The literature of the non-virulent or pseudo Bacillus diphtheriæ is still in its infancy. Hofmann, Loeffler, Escherich, Fraenkel, Welch, Abbott, and the writer of this article have studied it. Its rôle and exact place in the morphology of diphtheria are still a mystery. The German school of bacteriologists all unanimously agree as to its place among the harmless saprophytes. Fraenkel is an exception to this view and sides with Roux, who thinks that the non-virulent pseudo bacillus is a weakened form of the virulent bacillus and, under conditions not yet discovered, as stated was the case in charbon, may become a dangerous, virulent micro-organism.

In closing these studies upon diphtheria the writer wishes to emphasize the fact that the tonsil is an organ which possesses a circulatory activity hitherto not attributed to it. It was formerly looked upon as an anatomical appendage whose purpose was problematic. Stöhr has demonstrated the constant migration of leucocytes from the interior of the tonsil (follicles) to the surface, and therefore into the lumen of the lacunæ. The writer is inclined to believe that future work may reveal that the tonsil in this functional activity exercises a destruc-

tive influence upon pathogenic bacteria which may be on the surface of the tonsil or in the lumen of the lacune. Blood lymph and serum possess inherent destructive powers upon the life of bacteria (Nuttall, Buchner, Prudden). Leucocytes also have the power of attracting within their substance bacteria. Both these conditions exist in the tonsils. If we examine the lacunar plugs in lacunar diphtheria we find leucocytes which seem to contain within them cocci and bacilli. It may be that the prolonged retention of the Bacillus diphtheriæ for weeks in the depths of the lacunæ under the intimate influence of the above-mentioned phenomena of lymph and leucocyte activity may not be without effect on one phase of the vitality of the Bacillus diphtheriæ—its virulence. Such a theory as the above is

# PERFORATION OF THE APPENDIX VERMIFORMIS BY A WHITE BEAN.

REMOVAL OF THE APPENDIX AND A PART OF THE OMENTUM. BY HAL C. WYMAN, M.S., M.D.,

PROFESSOR OF SURGERY IN THE MICHIGAN COLLEGE OF MEDICINE AND SURGERY, DETROIT.

I was called by Dr. P. B. Le Blanc to see F. W. F., a salesman, aged twenty-five years, who had been under the doctor's care for four days. He began to complain of pain in his bowels, with diarrhea, twenty-four hours before the doctor saw him. He then had severe pain in the right side of the abdomen, and it was so severe that full doses of morphine were required to relieve it. He had fever also; his tongue was coated and pulse accelerated. Poultices were applied to the abdomen and hope expressed that the symptoms would soon disappear. On the contrary, however, he grew worse. Vomiting commenced and quantities of greenish fluid mixed with mucus were ejected at intervals of two or three hours. Medicine had no effect in controlling the nausea. Liquid foods were thrown up as soon as taken. His eyes sank into their sockets and dark circles appeared about them. His pulse and temperature did not vary materially from 90 beats and 101° F. We found the right side of the abdomen generally slightly tender on pressure. At a point midway between the anterior superior spine of the ilium and the umbilicus a sensation of unusual resistance was imparted to the fingers, unlike anything that could be felt in other regions of the abdomen. We decided that an operation was imperatively called for, to anticipate the collapse which the symptoms above described and the patient's general condition surely indicated. The situation was explained to him. He is a young man of marked intelligence and said that our view of his case corresponded with his ideas of his illness. He had "read in the newspapers of diseases and seeds in the blind sac of the intestine, and he thought he ought to have an operation performed." His language is quoted as nearly as it can be recalled here for the purpose of showing the clearness of his mind, notwithstanding the gravity of his symptoms.

Dr. C. B. Storrs was called to assist us. We had the patient's abdomen washed with soap and water, bad him placed on a table, and gave him chloroform until he was anæsthetized.

While his father held a lamp to illuminate the field of operation we cut a wound two inches long through the skin, fat, and fascia, over the most unyielding point we could find between the right anterior superior spine of the ilium and the umbilicus. Then we separated in turn the fibers of the external oblique, internal oblique, and transversalis muscles and exposed the peritonœum, holding the parts asunder with retractors. The parts adjacent to it were slightly cedematous. We incised it and introduced our finger. Immediately a quantity of foul-smelling pus spurted out. Exploring this abscess cavity with our finger, we soon found the appendix vermiformis with a large perforation, through which could be felt a hard substance which, on removal, we found to be a white bean. We drew the appendix up through the abdominal wound, ligated it with strong silk close to the cæcum, and cut it off. But one perforation was found in it, and that was just large enough to transmit the bean. The appendix was very dark in color, stained by the fæcal gases and pus.

Exploring the abscess cavity again with our finger, we found a tag of omentum very much blackened and about two inches and a half in length; this we ligated and removed. We next introduced a piece of nursing-bottle rubber tubing, five inches in length, perforated at intervals of an inch, into the deepest part of the abscess cavity, and around it packed loosely ten-percent. iodoform gauze. The wound was now covered with several layers of ten-per-cent. iodoform gauze, a thick layer of sterilized cotton, and an abdominal bandage. No sutures were used. The muscles were not cut. The wound through them and the peritonæum was just large enough to admit one finger.

The patient was placed in bed with warm bottles to his feet, though there was no coldness of his extremities, nor was the rate and rhythm of his pulse materially changed by the procedures just described. Anæsthesia passed off gradually. He came to his senses and expressed himself relieved of the pain which had disturbed him constantly since he was first taken sick. The dressings were not removed for two days; then Dr. Le Blanc took off the cotton and gauze, which were soiled with pus, and injected a teaspoonful of peroxide of hydrogen (fifteenvolume solution) through the tube and cleansed the abscess cavity. Gauze and cotton were reapplied. This dressing was repeated daily for a week. The gauze which had been inserted with the tube was then removed, the cavity was again washed out with a fifteen-volume solution of peroxide of hydrogen, which foamed freely from the wound; the tube was reinserted; the muscles from day to day grew snugger about it, and at the end of two weeks, pus no longer discharging, it was withdrawn, and a few days later the wound closed.

The writer thinks it is of great advantage to treat the muscles in this operation without cutting them. Two important purposes are gained by this method—viz., first, less risk of infection through the wound; second, less danger of subsequent ventral hernia. In fifteen consecutive cases for malignant appendicitis he has treated after this method within the past six months every patient has recovered health, and each has a perfectly cicatrized and sound abdominal wall.

The Erie County Hospital.—A competitive examination will be held at the hospital, Buffalo, about March 15th, to fill the positions of house physician, assistant house physician, and assistant house surgeon. The hospital contains three hundred and fifty beds and is the largest in the city of Buffalo. Full particulars about the examination and the positions can be obtained from the secretary, Dr. Francis T. Metcalfe, No. 329 Franklin Street, Buffalo.

# A CASE OF SITUS VISCERUM INVERSUS.

BY ALDRED S. WARTHIN, Ph. D., M. D.,
DEMON-TRATOR OF PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF MICHIGAN,
ANN ARROR.

Although numerous cases of situs viscerum inversus have been reported, the majority of these have been cases in which the condition was discovered only after death, at the post-mortem or dissection table. The discovery, therefore, of this anomaly in a living adult may become worthy of note because of the interest attached to the physical signs. Such a case having been discovered and thoroughly studied in our classes of physical diagnosis, I have considered it worth while to present a brief outline of the physical signs arising from such a condition.

The patient, Mr. A., is fifty-one years of age, an American, and a farmer. There is a history of epilepsy in the father's family. No other cases of abnormity in the family. As a child he was not strong. Is subject to epileptoid attacks, closely connected with gastric disturbances. For the last two years he has had diabetes mellitus.

Is of tall and slender frame; muscles poorly developed. Is left-handed. Patient himself has never suspected his condition, though he says his wife had told him that his heart was on the right side.

On inspection, a diffuse pulsation is seen on the right side in the fifth intercostal space, strongest just outside of the right parasternal line, and most plainly seen during expiration. This pulsation could be made evident to a large class by placing a flag upon the spot of strongest impulse. The shock of heart can be felt on the right side between the third rib and fifth interspace. Over the normal heart area on the left of the sternum no pulsation can be seen or felt.

Percussion boundaries show as a mirror image of those in the normal body, being completely reversed. The area of absolute heart dullness begins on the upper border of the fifth rib in 'the right sternal line and extends out almost to the apex beat, and to the median line over the sternum. It is continuous below with dullness extending to the left from the right sternal line. The area of relative dullness begins on the fourth rib, runs downward across the sternum, meeting relative liver dullness in the fifth intercostal space in the left sternal line. There is no dullness in the normal heart area on the left of the sternum.

The lower lung boundaries are on the seventh rib in the nipple lines. An attempt to locate the boundaries of the lobes of the lungs by means of auscultatory percussion, which in our hands has never given the satisfactory results obtained by some others, seemed to show that the lungs were also reversed—three lobes on the left side, two on the right. As further proof of this, vocal fremitus is stronger left than right; and auscultation shows that posteriorly over the bronchi the bronchial breathing is stronger on the left than on the right side.

In the area of normal liver dullness, beginning in the right nipple line on the seventh rib and extending between the right anterior axillary and sternal lines, there is a clear tympanitic note on percussion resembling that of the stomach. This extends two fingerbreadths below the edge of the ribs in the right nipple line, and curves up to the eighth rib in the anterior axillary. The lower lung boundary on the right side anteriorly is, therefore, a clear tympanitic tone, instead of the normal liver dullness.

Inflation of the stomach with CO<sub>2</sub> shows that this organ does lie in this area of tympanitic percussion sound, the inflated stomach rolling out from under the right edge of the ribs, filling in the right hypochondrium and right half of the epigastrium. Auscultatory percussion over this area gives the characteristic shock and silvery stomach tone. Succussion sounds can be also produced in this region, and the gurgling sounds produced in the stomach are heard in this region and not upon the left side.

There is a slight curvature of the dorsal vertebræ toward the left side, and upon auscultation, while the patient is drinking, the œsophageal gurgling is much louder upon the right side than upon the left, indicating that the position of the œsophagus is to the right of the spinal column.

Upon the right side, in the anterior and middle axillary lines, there is dullness extending from the seventh to the ninth rib, in size and shape corresponding to that of the spleen.

An area of absolute dullness corresponding to that of the liver begins in the left sternal line on the upper border of the seventh rib; in the left nipple line, on the same; in the middle axillary line, on the ninth; posteriorly, on the twelfth. The right border of this area of dullness is formed by the right sternal line. In the median line the lower border is four finger-breadths below the ensiform; in the left nipple line it is at the edge of the ribs. Above, on the right, this dullness is continuous with heart dullness. The half-moon-shaped space is thus filled in by dullness, which descends on inspiration, and in form and size corresponding to the area of liver dullness.

No heart sounds can be heard in the region of normal apex beat. On the right side, over the pulsation described above, they are distinctly audible. First sound, impure; second, normal. There is a faint diastolic sound in the right second interspace; one slightly louder in the left second interspace.

There is constant tympanitic note in the left iliac region, and inflation of the large intestine shows reversed arrangement, the sigmoid flexure and descending colon being on the right side.

The right testicle hangs much lower than the left, and there is a slight varicocele of the right spermatic veins.

These form the interesting combination of physical signs from which the diagnosis of complete situs viscerum inversus was made and are valuable because of their completeness.

The case was also exhibited in Dr. Dock's clinic of internal medicine, and the following points were there discussed: The existence of left-handedness, which has not been observed in all of the cases previously reported; the relation of the dorsal curvature to muscular action or to the position of the aorta and the cosphagus; and the position of the right testicle with coexistent varicoccle (it is not at all uncommon to find the right testicle lower than the left in persons of normal development). It was also suggested that it was probable that the condition was much more common than was generally supposed, since to many dissecting laboratories one or more such cases came in the course of a year.

The Colorado State Medical Society.—We have been asked to announce that members of the American Medical Association are cordially invited by the Colorado State Medical Society to stop in Denver on returning from the coast and attend the meeting of the society on June 19th, 20th, and 21st. Members who expect to return via Denver are invited to correspond with the secretary, Dr. A. Stewart Lobingier, Denver, that invitations to participate in the proceedings and proper entertainment may be arranged.

THE

# NEW YORK MEDICAL JOURNAL, A Weekly Review of Medicine.

Published by D. Appleton & Co. Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MARCH 10, 1894.

THE IMMEDIATE CAUSE OF CONVULSIONS IN CHRONIC NEPHRITIS.

When convulsions occur in an adult who is not the subject of chronic epilepsy or of bysteria, the urine is to be examined at once. If albumin is present, and especially if casts are found, the physician diagnosticates uraemia, and accepts this as a sufficient explanation of the onset of the convulsions. But this inference is insufficient. Why should a patient with chronic nephritis have a sudden outbreak of convulsions when the kidney disease is apparently no more intense than it has been for months or years past? Would not the ability of the human system to accommodate itself to slow disease-changes protect the patient from sudden outbreaks in chronic disease? If there is no sudden, marked change in the unwholesomeness of the blood that nourishes the nerve centers, why should nerve explosions occur?

Careful thought on these questions may convince our readers that in cases of nephritis pursuing an even, chronic course the occurrence of convulsions ought to lead to a search for acute intercurrent conditions elsewhere than in the urinary tract, and that the correction of these intercurrent conditions may be expected to relieve the patient of the convulsive status and to secure him against subsequent repetition of the paroxysms. These intercurrent conditions may be sought for in various regions of the body and in different functional disturbances. During childbirth the nerve irritation of inefficient attempts to expel the fœtus may bring on an eclamptic attack which would never have occurred, even in the presence of . chronic Bright's disease, had the labor proceeded swiftly or been promptly terminated by instrumental interference. In other patients, not parturient, excessive mental anxiety or physical overfatigue may excite convulsions when without these exciting conditions nephritis would have gone on for years without sign of spasm.

Disturbances of the digestive tract are well known as tending to precipitate convulsions in the chronic epileptic; and it is very probable that acute disorders of this tract, whether arising from "catching cold," with its inward congestions and check of secretions, or from the ingestion of unwholesome food, or from constipation, are often the immediate exciting causes of convulsions in patients with chronic nephritis.

The influence of such acute disorders of the digestive processes upon the ever-sensitive convulsive centers in childhood is universally admitted; and there are reasons for believing that in chronic nephritis of the adult, where the nervous system is in an abnormally sensitive state, these same centers may in like manner be stirred to sudden explosive action, either by reflex irritation from the nerve-endings of the intestinal canal or through the absorption of abnormal digestive or fermentative products into the circulation and consequent excitement of the convulsive nerve matter.

When, therefore, convulsions occur in chronic nephritis, we should look beyond the chronic condition and seek for an acute intercurrent cause; and, if that is found, we should, without neglecting the treatment of the nephritis, devote proper attention at once to the removal of this exciting cause.

#### THE QUIZ SYSTEM.

Ir must be accepted as a self-evident fact that the object of a professional school is so to prepare and instruct its students that, after graduation, they shall be properly qualified to practice the profession for which they were trained. This object the schools more or less perfectly attain by means of didactic lectures, and, as tests, use examinations. To these essential elements of professional education are sometimes added demonstrations, practical work, clinical teaching (in the case of the medical schools), and sometimes recitations.

It would seem as if by these methods all possible means and aids to education were provided, and it is certain that by them alone many a man is educated and fitted for a life of professional usefulness and brilliancy, yet there has sprung up beside but independent of these courses of instruction a system of supplementary and private instruction of which a large number of professional students avail themselves. This is the tutoring or "quiz" system.

Many arguments have been brought to bear against this system, and perhaps the most valid is that, if a school pretends to educate its students properly, it should be unnecessary for them to have instruction without its walls. Theoretically this may be unanswerable; practically it is absurd, and many a bewildered but otherwise able man has been tutored into grasping ideas he had failed to grasp in the lecture room. But, if it is true that all professional schools should by their very existence (if they are what they should be) inhibit quizzing or tutoring upon their courses, then are we at a sorry pass indeed, for it is probably true that there is not an academic, scientific, or professional school in the world in which this system does not appear to a greater or lesser extent. But, again, say the critics, if this system is so widespread and therefore presumably so important, the school itself should do the quizzing, else it fails in its duty. Theoretically, again, perhaps correct; practically, impossible, for no school could by any chance divide its students up into such small groups as is done in private quizes. And thereon depends the whole question. It is the personal association and acquaintance between master and student that makes the system of tutoring what it is-the personal coaching and supervision of the quiz-master for the student, whom he studies and knows.

True, there are many students who are unable to avail themselves of these advantages, and to them the system may seem unjust and but another luxury they must deny themselves,

But, if it is a luxury, the school provides the necessities, and on educational necessities alone have many of our greatest men been brought up.

If the quiz system has critics, so has it advocates who regard it as a beneficial and proper, though accessory and, strictly speaking, unnecessary, adjunct to teaching in the professional school; who, in reply to the demand that a college shall render a quiz impossible by its own "required" recitations, hold the "university" idea and say that to offer instruction, not to compel it, is the function of a professional school.

In advocating the quiz system we may lazily and indolently commit ourselves to the fallacy that what was good enough for our fathers is necessarily good enough for us, we may point to the failure of attempted "college quizes"; but after all is said the surest proof of the value of the system is not its survival but its growth.

# MINOR PARAGRAPHS.

#### AN ABORTIVE TREATMENT OF CORYZA.

Dr. J. Gerard, in La Médecine modérne, reports some very good results which he has obtained by the use of inhalations of chloroform in arresting the extension of coryza to the bronchial tubes. He at first employed a mixture of carbolic acid and ammonia, but this was finally replaced by chloroform, which was found to act much better. The inhalation is to be practiced several times up to the point of the first signs of anæsthesia. When this has been done at the time the first nasal symptoms appeared, no further extension of the affection has occurred. In epidemics of coryza and influenza, even in cases where the catarrhal condition was severe, the author has seen the disease aborted.

#### HYSTERICAL MENORRHAGIA.

M. Right, in the same journal, says that there are many more cases of simple menorrhagia, where the flow may be very abundant and painful, due to hysteria than is generally supposed. In these cases the patients are perfectly well during the interval. Examination during the attack reveals intense congestion of the uterus and ovaries, and in some instances the ovaries are easily palpated. The symptoms in some cases are very severe—great pain, convulsions, and profuse hæmorrhage. These patients recover very rapidly after an attack, and nothing remains of the congestive condition. Such cases occur mostly in young, highly emotional women.

### LACTOPHENINE.

At a recent meeting of the Paris Société de biologie, a report of which is published in the Union médicale for February 10th, it was stated that M. Londowski had experimented on a number of patients in M. Proust's service with a substance allied to phenacetine which he called lactophenine. This body is at once antineuralgic and hypnotic, and may be employed in daily amounts of from ten to forty-five grains, in divided doses. The only after-effects observed, and those are by no means constant, are a little sweating and giddiness.

# THE ACTION OF POISONS ON THE FŒTUS.

La France médicale contains a report of a recent meeting of the Académie de médecine at which M. Porak gave the results of extended experiments on the placenta with various substances. He concludes that arsenic, copper, atropine, phosphorus, mercury, and alizarin do not pass through the placenta, but that copper and mercury have a cumulative and elective action upon that organ. The poisons accumulate in greater quantities in the tissues of the fœtus than in those of the mother, and their diffusion also is greater in the fœtus, for they are found in the liver, in the central nervous system, and in the skin, while in the mother they are found almost exclusively in the liver.

### A PROPOSED BUILDING FOR PHYSICIANS' OFFICES.

ELSEWHERE in this issue we give the leading points of a scheme for the construction and management of a large office building for the almost exclusive use of physicians. This will be a novelty in New York, where a physician's office is almost invariably a portion of his residence. There is much to be said in its favor, especially as a means of enabling the younger members of the profession to economize and at the same time enjoy the advantage of office accommodations far superior to what they could hope to obtain in much more expensive quarters in a dwelling. If it is prudently managed, we have no doubt the experiment will prove successful.

#### THE CONGRESS OF NORWEGIAN PHYSICIANS.

This congress was recently convened at Christiania, but, instead of hiring a hall in which to hold the daily sessions, it chartered a large steamer, which moved from place to place along the coast. The members were thus enabled to have a plentiful supply of fresh air and a change of scene while continuing their discussions of medical subjects.

#### ITEMS, ETC.

Infectious Diseases in New York,—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 6, 1894:

DISEASES.	Week ending Feb. 27.		Week ending Mar. 6.	
22022000	Cases.	Deaths.	Cases.	Deaths.
Typhus	0	0	()	0
Typhoid fever	9	2	5	3
Scarlet fever	134	12	184	15
Cerebro-spinal meningitis	2	1	()	2
Measles	430	31	478	27
Diphtheria	188	61	203	52
Small-pox	37	9	23	3

The New York Hospital Library.—Among notable gifts of books that have been made to the library recently are that of nearly two hundred volumes from the library of the late Dr. Gurdon Buck, presented by his son, Dr. Francis D. Buck; and that of Dr. D. B. St. John Roosa's collection of otological books. Dr. Roosa, who was formerly on the house staff of the hospital, gave these books in anticipation of the provisions of a will, made by him some time ago, whereby the library was to receive his medical books.

The Western Reserve (Ohio) University.—The commencement exercises of this institution were held at Cleveland on February 28th, and a class of twenty-one was graduated. An address was delivered by Professor William H. Welch, of the Johns Hopkins University, on Higher Education in Medicine. The university was the recipient of donations amounting to \$300,000. Of this amount, \$257,000 was for the erection and equipment of a physical laboratory. The degree of LL. D. was conferred upon Professor Welch and upon Dr. J. C. Reeve, of Dayton, Ohio, an alumnus.

The Society of Medical Jurisprudence.—The special order for the next meeting, on Monday evening the 12th inst., at the Academy of Medicine's building, is a paper on Hypnotism, Insanity, and Legal Responsibility, by Mr. Charles M. Demond, of the New York bar.

The German Medical Society of the City of New York.

—At the last meeting of the Deutsche medicinische Gesellschaft der Stadt New York, on Monday evening, the 5th inst., Dr. S. J. Meltzer was to read a paper on Myxedema, and Dr. S. Breitenfeld one on Sexual Impotence and its Cure.

The Association of Military Surgeons of the United States will hold its fourth annual meeting in Washington on the 1st, 2d, and 3d of May, under the presidency of Dr. Nicholas Senn, of Chicago.

The City (Charity) Hospital.—The regular examinations of candidates for appointment as junior assistants on the house staff will be held at the hospital on Thursday, the 15th inst., at 2 P.M.

The Cleveland Medical Society.—The programme for the meeting of Friday evening, the 9th inst., included the following papers: Bladder and Ureter Work in the Female, by Dr. Howard A. Kelly, of Baltimore; and Hypnotism, by Dr. M. J. Parke.

The Death of Professor William Leishman, the distinguished Glasgow obstetrician, is announced in the Lancet as having taken place on Sunday, February 18th. He was in his eightieth year.

The Death of Dr. Henry C. Cooper, the clerk of the faculty of the Medical Department of the University of the City of New York, is announced as having occurred suddenly on Sunday, the 4th inst. The deceased was a graduate of the school of the class of 1881.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the week ending March 3, 1894;

ASHBRIDGE, RICHARD, Passed Assistant Surgeon. Dismissed from the naval service February 28, 1894, by the President's approval of the sentence of general court-martial.

CABELL, A. G., Passed Assistant Surgeon. Ordered to the U.S. Steamer Michigan.

SAYRE, J. S., Passed Assistant Surgeon. Detached from the U. S. Steamer Michigan and ordered to the Naval Hospital, New York.

BRODERICK, R. G., Assistant Surgeon. Detached from the Naval Laboratory and Department of Instruction and ordered to the Naval Hospital, Mare Island, California.

# Society Meetings for the Coming Week:

Monday, March 12th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society (private), New York; Society of Medical Jurisprudence, New York; Boston Society for Medical Improvement; Gynæcological Society of Boston; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private); Baltimore Medical Association.

Tuesday, March 1:tth: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); Kings County, N. Y., Medical Association; Medical Societies of the Counties of Chemung (quarterly—Elmira), Rensselaer, and Ulster (quarterly), N. Y.; Newark, N. J., Medical Association; Trenton, M. J., Medical Association;

ciation (private); Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Baltimore Gynæcological and Obstetrical Society; Practitioners' Club, Richmond, Ky.

WEDNESDAY, March 14th: American Microscopical Society of the City of New York; Metropolitan Medical Society (private), New York; New York Pathological Society; New York Surgical Society; Medical Societies of the Counties of Albany and Montgomery (quarterly), N. Y.; Pittsfield, Mass., Medical Association (private); Worcester, Mass., District Medical Society (Worcester); Philadelphia County Medical Society.

THURSDAY, March 15th: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Mass., Society for Medical Improvement (private).

FRIDAY, March 16th: New York Academy of Medicine (Section in Orthopædic Surgery); Baltimore Clinical Society; Chicago Gynæcological Society.

SATURDAY, March 17th: Clinical Society of the New York Post-graduate Medical School and Hospital.

# Proceedings of Societies.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Eighty-eighth Annual Meeting, held in Albany, on Tuesday, Wednesday, and Thursday, February 6, 7, and 8, 1894.

The President, Dr. HERMAN BENDELL, of Albany, in the Chair.

(Continued from page 184.)

Diphtheria.—In the continuation of the discussion of this subject, Dr. Thomas E. Satterhwatte, of New York, said that he believed that membranous croup and laryngeal diphtheria were histologically one. The value of the bacteriological work in this field could not be questioned. To it we were indebted for the discovery of the toxines, antitoxines, albumoses, and bacilli pertaining to the disease, but he was not quite prepared to admit all that had been asserted by the bacteriologists. The virus of diphtheria was very persistent, retaining its vitality a long time, which accounted for the diffusion of the disease as an epidemic.

Dr. A. Jacobi, of New York, took issue with those who objected to the local treatment of diphtheria. He agreed with those who advocated large quantities of alcohol. The latter was not a toxic agent until the period of convalescence was reached. Tincture of chloride of iron was a tried and standard remedy, but it was not equally well tolerated by all stomachs. The bichloride of mercury, in solutions of 1 to 6,000 or 1 to 8,000, was readily tolerated almost invariably, and in his judgment was the most valuable of all the remedial agents employed.

Dr. Wood, of Richmond County, had found great satisfaction in the use of inhalations of tar and turpentine, which had not been mentioned by any of the previous speakers.

Dr. H. R. HOPKINS, of Buffalo, advised the use of alcohol per rectum for very young infants, with whom the same agent would not be tolerated by the stomach.

Dr. Seymour, of Troy, hoped that the recommendation in Dr. Suiter's paper, that the diagnosis of suspicious or supposed cases of diphtheria be referred in each county or town to the appropriate health official, would be formally indorsed by the society.

Dr. BAILEY expressed his preference for calomel rather than

corrosive sublimate as the best agent thus far available in the treatment of diphtheria.

Treatment of Depressions in the Skull of the New-born. -Dr. DAVID D. JENNINGS, of New York, believed that the plan of leaving the cure of these cases to Nature was not justifiable in the present age of advanced cerebral surgery, for, while some cases ended in recovery and the infants suffered no serious consequences, many cases of hemiplegia, epilepsy, and impaired intellect resulted, and the deformity, especially in the frontal indentations, often persisted. Many of these infants died shortly after birth, and raising the depressed bone by the operation of trephining would have saved some of them, besides anticipating subsequent cerebral trouble. Dr. Jennings successfully trephined the skull of an infant, forty hours old, for a marked depression of the left frontal bone, the boss frontis presenting a concavity equal to the usual convexity. After the surrounding bone had been lifted into position with an elevator, the removed button was replaced, and the wound closed with catgut sutures and drainage. Antiseptic dressings were applied, and the infant was soon quietly nursing at its mother's side.

The operation was simple and apparently without shock. No anesthetic was employed, and it was not necessary to tie a vessel. The wound healed by primary union, and the infant made an uneventful recovery.

The following conclusions were offered:

- 1. Use pneumatic traction. If this failed, trephining was the best operative procedure.
  - 2. Trephining, per se, was not a dangerous operation.
- The removed button of bone could be replaced with good prospect of its union on account of the vascularity of the bones at this age.
  - 4. Frontal depressions rarely corrected themselves.
- 5. Immediate action was desirable, if there were symptoms which indicated operation.
- If the depression was still exaggerated at the end of two weeks, an operation to prevent subsequent brain trouble and overcome the deformity should be performed.

Dr. Andrew F. Currier, of New York, called attention to the theory which Marion Sims advanced many years ago, that convulsions in the new-born infant were the result of the prone position with pressure on the occipital bone. That theory had not been generally accepted. Dr. A. Jacobi had also called attention in more recent years to the influence of cranial pressure in prolonged labors in producing impairment of cerebral and mental development. In the cranial injuries resulting from obstetrical operations the speaker's observation had been that convulsions and early death were the almost uniform result. That would tend to deter him from performing such an operation as trephining upon the new-born. He did not doubt, however, that there were cases in which the operation was indicated and could be performed successfully. The case under discussion was one of that character, and he congratulated the reader on his success, as well as the manner in which he had treated the subject.

Dr. Carter S. Cole, of New York, observed that it was not the depression of cranial bone so much as the injury to the membranes and cerebrum which called for operative treatment, and thought that surgical injury in operation would be minimized by using the chisel and mallet rather than the trephine. With such instruments there would also be the least possible loss of cranial substance.

Dr. A. M. Phelps, of New York, approved of operation in such cases as were under discussion, and trephining in preference to the use of chisel and mallet. He narrated cases and presented photographs of patients in which epilepsy had been relieved by such treatment.

Senile Endometritis.—A paper with this title, by Dr. A. J. C. Skene, of Brooklyn, was read by Dr. Buckmaster. The prevailing opinion that the senile uterus was subject only to malignant disease was not true. Certainly it was rarely susceptible to gonorrhea and other acute infectious diseases, which were so common in early life. The form of endometritis which was not uncommon in the aged was quite different from the endometritis of earlier life. This was due to the histological changes of an atrophic character which had taken place in the organ. The entire mucosa might be involved, or only that of the portio vaginalis. The most noticeable symptom of the disease was an offensive sero-purulent discharge. There was also stricture, more or less pronounced, at the os internum, and sometimes at the os externum. This would cause intermittence in the appearance of the discharge, and that characteristic would be the more marked if the uterus were retroflexed. In addition to retroflexion as a causative condition might be mentioned myomata of the uterus. In addition to the discharge there might be acute pain, especially with stenosis at the os internum. Aspiration of the uterine cavity was sometimes necessary in order to settle the diagnosis. The treatment was not always satisfactory or as efficient as might be desired, and might consist in the free use of hot disinfecting solutions to the vagina and uterine cavity; astringent tampons in the vagina, especially of iodoform, and peroxide of hydrogen; also, if fissure of the os was present, trachelorrhaphy. If the disease was complicated with prolapse of the uterus, hysterectomy might be required and would be warrantable.

The Treatment of Endometritis.—Dr. H. E. Hayd, of Buffalo, regarded this disease as of unusual importance from the fact that it was initial to so many of the diseases of the pelvic organs. It might be acute, subacute, or chronic, and involve the entire endometrium or that of the cervix or the corpus alone. The treatment of the acute form should consist in dilatation, irrigation, curettage, tamponade with gauze, and, what was quite as important, rest in bed, with the use of easily digested food and especial reference to an open condition of the bowels.

The subacute form was frequently caused by fissure of the os, and required, in such cases, suitable operative procedures in addition to the use of suitable local astringents, including galvanism. It was scarcely necessary to insist that all means of treatment should be employed with the utmost cleanliness.

In the chronic form of the disease there very often was extension to the tubes, ovaries, and peritonæum, and if the tubes and ovaries became at all involved the question of an abdominal operation was always to be borne in mind. Conservatism should be the rule, however, and the more serious operation should be deferred until it was determined that curettage and drainage would not suffice.

Dr. W. E. Ford, of Utica, was an advocate of the use of galvanism in all cases in which the peritoneum or the tubes were not seriously diseased. It was not indicated in cases in which there was pus in the tubes or in cases in which perimetric adhesions seriously impaired the mobility of the uterus. If curettage was performed, he thought the dull was usually preferable to the sharp curette, and if the uterus was tamponed, the tampon should not be too firm, as drainage would then be imperfect.

Normal Menstruation.—A discussion on menstruation and its abnormities was introduced with a paper on this subject by Dr. Andrew F. Cuerier, of New York. (To be published.)

Dysmenorrhæa, its Causes and Treatment.—Dr. How-ARD A. Kelly, of Baltimore, insisted that dysmenorrhæa was no disease, though often regarded as such by the general practitioner. It was simply pelvic pain associated with pelvic congestion, and was a symptom common to numerous diseases Its frequency was seen in the fact that, of four hundred cases in which he had performed abdominal section in women, dysmenorrhea had been reported as a troublesome symptom in two hundred and ninety-one. In more than half the cases in which the minor pelvic disorders were present, dysmenorrhæa was associated. Of fifty-two cases in which retroflexion of the uterus had been pronounced, dysmenorrhœa had been annoying in forty-one. The symptom was also annoying in many cases in which small tumors of different varieties were found in the pelvis, and in many women who were neurotic and hysterical. The habitual prescription of morphine as a means of relieving such trouble was immoral unless the pain was associated with gross pelvic lesions. For the treatment of dysmenorrhoa in young girls, reliance should be placed upon proper diet and hygiene, rest in bed during menstruation, and suitable medication to keep the bowels freely open.

The speaker believed that the local treatment of young girls for this symptom was usually unnecessary and inadvisable. In general it might be said that dysmenorrhœa would be relieved when the local cause producing it was removed; this might imply the removal of the uterine annexa. He was prepared to advocate such an operation, even if the organs were without gross lesions, if the health of the individual was being wrecked by the persistently recurring pain. Dilatation of the uterus was useful as a means of treatment in many cases. A cure was produced by such means in about ten per cent., while in a much larger percentage the relief obtained was considerable.

Profuse Menstruation .- Dr. Charles P. Noble, of Philadelphia, said that the causes of this condition were many and might be either local or general in character. It was also a suspicious symptom with women who had passed their fortieth year, for then was the period of degeneration and development of malignant disease. The idea was now an exploded one that profuse menstruation during the period of the menopause was necessary and of no consequence. It had often happened that cancer of the uterus developing during the menopause had been overlooked by the physician until the time had gone by when a radical cure was possible. Profuse menstruation in young women, on the other hand, was, as a rule, the sign of endometritis in one or another of its various forms. There was no routine treatment for the cure of this condition; each case was to be studied and treated by itself. As physical weakness was an almost inevitable attendant, it was a good rule to prescribe strychnine, digitalis, and ergot, and, while this treatment might suffice for some cases, it would be more consistent with scientific accuracy to follow it up in all cases with a careful physical examination to determine the exact condition of the pelvic organs. Pelvic congestion alone seldom caused profuse menstruation, but it predisposed to it, and hence was of significance. If the cause was found to be endometritis, curettage was indicated; if malignant disease, hysterectomy as early as possible. A sufficient time should be allowed when possible to improve the patient's general condition in preparation for the major operations. One of the preparatory or palliative operations which would sometimes be found useful consisted in the ligation of the uterine arteries per vaginam. Another useful measure was the application of strong caustics to the endometrium followed by tamponade of the cavity. This would bring away a slough composed of more or less of the structure of the uterus. The measure was somewhat dangerous, especially for cases in which the annexa had not previously been removed. In young virgins the condition was usually functional and was due to rapid growth at the period of puberty. In such cases it was usually curable without operation. In childbearing women it was usually due to some fault at or subsequent to parturition, and operative treatment might be necessary to relieve it. The important facts to be remembered were, that, when it occurred subsequent to the fortieth year, it might be expected to indicate approaching malignant disease; that examination to detect its cause was requisite in all cases, except occasionally among the young and unmarried; and that, if it was simply an indication of pelvic congestion, it could often be effectively treated by general measures.

Scanty Menstruation,—Dr. Franklin Townsend, of Albany, read a paper with this title. (To be published.)

Irregular Menstruation .- Dr. E. W. Cushing, of Boston, considered first the irregularities of the establishment of menstruction at puberty. These consisted in some cases in profuse hæmorrhage, and in others in scanty, delayed, or omitted menstruation. A certain amount of irregularity was to be expected, both at this period and at the menopause, and it was to be enjoined upon girls with whom the function was being established that study should not be too severe or confining, and that as much time as possible should be spent in the open air in the enjoyment of healthy exercise. As to the diagnosis between irregular menstruation and other bloody discharges from the vagina, first in importance were the sudden and severe hæmorrhages at or near the menstrual epoch, or the total suppression of menstruation due to inflammation of the appendages and of the fundus uteri, which were usually ascribed to "catching cold." Many troubles, even such as were serious in character, might follow such an attack. Irregularities were also associated with subinvolution of the uterus, and were frequently susceptible of relief only by surgical measures. Extra-uterine pregnancy also had associated with it irregularities of menstruation; in fact, this might be the first symptom calling attention to the condition. The peculiarities of the flow of blood were such that the patient seldom knew whether she was pregnant or not.

Irregularities during the middle period of married life were quite common among those who had been repeatedly pregnant and had had household cares in abundance. It was of great importance that such cases should be carefully followed and the presence of disease of more or less serious character discovered in time to treat it effectually. Myoma uteri at such a period was most likely to be troublesome, and the effort should be made to distinguish it from other conditions at the earliest possible moment. Irregularities due to the presence of fissured or lacerated cervix were often relieved by the performance of trachelorrhaphy.

Besides cancer, the occurrence of irregular hæmorrhages, especially in cases in which it was supposed that the menopause had occurred, was suggestive or indicative of malignant adenoma. The condition might also be due to diseases of the heart, violence of the emotions, sexual excitement, etc.

The Menopause, Natural and Artificial. - Dr. ARTHUR W. JOHNSTONE, of Cincinnati, remarked that the close of the nineteenth century would see the emancipation of the uterus from the thralldom of the ovary. The two organs were entirely independent of each other. Steavenson's law had elucidated the physiology of the reproductive organs. Its parallel in the nervous system was the every-day occurrence of sleeping and waking, anæmia of the brain during sleep and congestion in the waking hours. The body and limbs were larger in the sleeping than in the waking hours, owing to the excess of blood derived from the brain. This wave process of twenty-four hours' duration was analogous to the menstrual wave, in which the duration of the cycle was twenty-eight days. The acme of its pressure was at the beginning of the menstrual flow, the trough of the wave shortly after the flow was over, then a long, low tracing for three weeks, increased at the beginning of the

fourth to the point where the rupture of the vessels, with the menstrual flow, began. In addition to the menstrual wave, Steavenson had proved that there were associated a urea wave and a carbonic-acid wave, and that increased oxidation occurred a few days before menstruation came on, burning up the material in the mother's blood which was there for the nourishment of a fœtus. He had also shown the truth of the old saving that "the normal state of a woman was pregnancy." The excessive material was got rid of by oxidation when impregnation did not occur. Such was the meaning of menstruation. The active urea and carbonic-acid changes did not begin in the woman until the period of puberty, when a number of wellknown and interesting phenomena were observed for the first time. The recurring phenomena of menstruation occurred only during the period when physical activity was at its best. When the childbearing period was over there was necessarily a conservation of the vital forces, for their resisting power had been diminished. The first positive mark of this was seen in the wearing out of the endometrium, an adenoid structure like Peyer's patches. In place of new tissue rapidly formed and changed, the endometrium was converted into old fibrous cicatricial tissue. The nervous-system activity now found its expression in the sudden flashes of heat and cold, instead of in the vascular system of the pelvis, in vertigo, headache, and biliousness, the particular form of disturbance manifesting itself in that organ or apparatus which was always most inclined to disturbance. In this way the various affections which were so prone to develop about the period of the menopause could be accounted for. Of these, diabetes of the menopause was a good example. The previous individual and family history of the woman would have much influence upon the way in which she would experience the menopause. In the artificial menopause the important object to be sought was the cutting of the nerves, which had much to do with the control of menstruation, if the pelvic organs were so diseased that their removal was necessary. The nerve center which presided over menstruation was probably a mixed one; its exact situation was not known. To destroy all the nerves of control, a considerable portion of the broad ligament must be removed.

(To be continued.)

# Book Notices.

Vertebrate Embryology: a Text-book for Students and Practitioners. By A. MILKES MARSHALL, M. D., D. So., M. A., F. R. S., Professor in the Victoria University, etc. New York: G. P. Putnam's Sons. London: Smith, Elder, & Co., 1893. Pp. xxiii-640. [Price, \$6.]

The chief aim of this work seems to be to enlighten the student of human embryology upon the analogies between the development of the lower vertebrates and that of man, and it is written in such a clear and interesting style that it must succeed in great measure in accomplishing this object. In an introductory chapter a general account is given of the development of animals and of the structure, maturation, fertilization, and segmentation of the ovum. Then in succession the process of development of amphioxus, the frog, the chick, the rabbit, and the human being is outlined. About two hundred pages are devoted to human embryology. From this portion of the work we quote the following paragraphs on ovulation and menstruation as showing the excellence of the author's method of dealing with the subject: "From the time of puberty, and

BOOK NOTICES.

throughout the whole of the childbearing period of life—i.e., from about the fifteenth to about the forty-fifth year—the gradual maturation of the Graafian follicles, ending in rupture of the follicles and discharge of the ova, is continually going on: and in the healthy condition this discharge of ova occurs, not in an indefinite manner, but at regular and usually monthly intervals, one or more ova being set free at each period. This periodical maturation and discharge of ova is spoken of as ovulation. It goes on independently of sexual intercourse or of any kind of influence from the male, but it is possible that, as held by many authorities, the discharge of ova, though in no way dependent on sexual intercourse, may yet be hastened by this.

"Menstruation is the periodical discharge from the uterus of a certain amount of blood, mixed with mucus from the uterine glands and with epithelial and connective-tissue cells derived from disintegration of the mucous membrane of the uterus itself. There is a close connection between menstruation and ovulation. Both processes commence at puberty, and last throughout the childbearing period. They both recur periodically, and, further than this, the intervals are the same, and the two processes occur, as a rule, simultaneously."

"Menstruation, i. e., the actual discharge from the uterus of blood and other matters, is not an isolated process, but is the terminal act of a series of changes which occur at regular intervals in the walls of the uterus and of which the sequence is as follows: In the quiescent condition the uterus is lined by a smooth mucous membrane of a soft, spongy consistence and pale-red color. It consists of a single layer of ciliated epithelial cells, resting on a very delicate basement membrane, beneath which is the connective-tissue layer of the mucous membrane. This latter is about 1.5 millimetre in thickness, and consists of connective tissue, with very numerous connective-tissue cells, and traversed by irregularly arranged muscle fibers. It is attached by its outer surface to the muscular wall of the uterus. The epithelium lining the uterus is pitted to form the uterine glands. These are tubular glands, imbedded in large numbers in the connective-tissue layer of the mucous membrane, vertically to the inner surface of the uterus; they are straight or slightly convoluted, their blind or outer ends are usually slightly dilated, and they secrete a transparent, glutinous, alkaline fluid.

"The changes in the mucous membrane accompanying mensuration commence with congestion and tumefaction of the mucous membrane lining the entire uterus. This swells up considerably, becoming softer and more vascular than before, and forming ridge-like folds which project into the cavity of the uterus. The connective-tissue cells increase considerably in number, and the uterine glands become longer, wider, and more convoluted. The whole layer of mucous membrane increases in thickness from 1.5 millimetre to from 3 to 5 millimetres, while the glands increase in diameter from 0.08 to 0.12 millimetre. This swollen and hypertrophied mucous membrane forms what is called the menstrual decidua.

"At the menstrual period the superficial layer of the mucous membrane, about a fourth of the entire thickness, breaks down and is thrown off, usually in detached fragments, but sometimes, in cases of dysmenorrhoa membranacea, as a single piece, forming a complete cast of the interior of the uterus. Fatty degeneration has been noticed in these cast-off cells, but only in the later stages, after the menstrual discharge has actually commenced.

"This disintegration and casting off involves the loss of the epithelial lining of the uterine cavity, of the mouths of the uterine glands, and also of about one fourth of the entire thickness of the swollen mucous membrane. It of necessity causes rupture of the blood-vessels of the detached portions, and so

occasions more or less free hæmorrhage; and the blood so discharged, together with the broken-down mucous membrane of the uterus and with a certain amount of mucus from the uterine glands, forms the menstrual or catamenial flow."

"On the cessation of the menstrual flow, the uterine epithelium is very quickly generated, spreading over the surface from the necks of the uterine glands. It is completely reformed within three or four days at the end of the menstrual period. After this re-establishment of the uterine mucous membrane, the uterus remains in a quiescent condition for from ten days to a fortnight; at the end of this time it begins to swell again, and the menstrual process is repeated."

"The complete menstrual cycle, occupying in typical cases twenty-eight days, may be divided into four stages, which follow one another in regular sequence.

"The first or constructive stage is characterized by swelling of the nucous membrane, enlargement of the uterine glauds, and increase in the connective-tissue cells of the nucous membrane; it results in the formation of a menstrual decidua lining the entire uterus.

"The second or destructive stage includes what is ordinarily known as the menstrual or catamenial period. It is marked by abundant discharge of mucus from the enlarged glands and by the disintegration and discharge from the uterus of the inner layer of the mucous membrane. It involves loss of the epithelial lining of the uterus and of the necks of the glands, and is accompanied by hæmorrhage.

"The stage of repair comes next, during which the uterus is recovering from the destructive changes. The uterine epithelium is restored by growth from the lips of the deeper parts of the uterine glands, and the swelling of the mucous membrane subsides.

"The fourth stage is the period of quiescence, during which the uterus, having regained its normal structure, remains without further change until the commencement of the next succeeding constructive stage.

"The actual and relative durations of the several stages enumerated above are not determined with certainty, and are subject to individual variations. It will, perhaps, be right to assign about a week to the constructive stage, rather less than a week (five days on an average) to the destructive stage, three or four days to the stage of repair, and twelve or fourteen days to the quiescent period, the four stages together occupying the twenty-eight days which make up the normal menstrual cycle."

"Concerning the first or constructive period, there is hardly any room for doubt that it is to be regarded as a preparation on the part of the uterus for the reception of an ovum. The several stages of the process correspond closely, in essential respects, with those that occur in the placental lobes of the rabbit's uterus from about the fourth to the eighth day. In the rabbit, as in the human uterus, there occur swelling of the mucous and submucous tissues, increased vascularity, a large increase in the number of the connective-tissue cells, and a great enlargement of the uterine glands, which become larger, wider, and more freely branched. These changes, in the rabbit's uterus, are clearly related to the nutrition of the embryo, for it is to this hypertrophied and modified area of the uterine mucous membrane that the embryo becomes attached on the eighth day, and it is from this area that the maternal part of the placenta is formed.

"The most important difference between the rabbit's and the human uterus, as regards these stages, is that in the rabbit the ovum, or rather the blastodermic vesicle, is present within the uterus during the whole of the series of changes, although it lies quite freely and does not acquire attachment until the eighth day, while in the human uterus, on the other hand, the

menstrual constructive process goes on without the stimulus afforded by the presence of an ovum.

"As regards the actual changes in the uterus itself, the resemblance between the two cases is so great that it seems necessary to suppose that their significance is the same; and it must, therefore, be concluded that the human uterus periodically prepares itself, by the formation of a decidual lining, for the reception of an ovum, the process occurring at monthly intervals throughout the childbearing period, and quite irrespectively of the presence or arrival of a fertilized ovum.

"The second or destructive stage, constituting the act of menstruation in the ordinary sense of the term, is much more difficult to explain. At first sight it appears to consist simply in a rapid and somewhat violent undoing of the work accomplished in the preceding stage. If, however, it is compared with the changes that take place in the rabbit's uterus during gestation, it is found that the human uterus at the end of the constructive period of menstruation has reached a stage corresponding to that of a rabbit's uterus at the end of the seventh or beginning of the eighth day of pregnancy, when the blastodermic vesicle is still lying freely within the uterus, but is just about to acquire its attachment. In the rabbit this attachment is effected, early on the eighth day, by fusion of the wall of the blastodermic vesicle with the epithelium of the modified and hypertrophied placental lobes of the uterus. This fusion is immediately followed, or rather is accompanied, by degenerative changes in the uterine mucous membrane opposite the area of attachment, which rapidly leads to absorption of the uterine epithelium, and of the mouths and necks of the uterine glands.

"Similar changes occur during the formation of the human placenta, and, . . . inasmuch as the portion of the wall of the uterus which is concerned in the changes is the same in menstruation and in pregnancy, the menstrual discharge may be viewed, not merely as a destructive process, but as corresponding in a modified form to the rapid absorption of the same parts which occurs normally during pregnancy.

"The constructive stage of menstruation, and, as just seen, the destructive stage as well, may be regarded as phases in the preparation of the uterus for the formation of a placenta; stages which can be carried up to a certain point without needing the stimulus of the presence of an ovum or embryo, but which, having reached a point at which further development is impossible without an embryo, stop abruptly. The constructive stage has been shown to be an active preparation of the uterus for the reception of a fertilized ovum; the succeeding or destructive stage is not to be regarded as a simple undoing of this preparation, but as a further continuance, in a modified form, of the act of preparation, which leaves the uterus in a condition in which, for further elaboration to occur, the presence of an embryo is indispensable.

"Ovulation and menstruation, or the discharge of ova from the ovary and of the disintegrated decidua from the uterus, are processes which occur periodically and, as a rule, simultaneously; and it becomes a matter of interest to inquire into the nature of the connection between them. The ovaries swell up and become tender at monthly intervals. The enlargement commences, as a rule, a few days before the menstrual period. attains its maximum about the time of the period, and gradually subsides after the period is over. As the ovary is known to become congested just before the rupture of a Graafian follicle and the discharge of an ovum, it appears a fair inference that this discharge occurs about the same time as the menstrual flow-i. e., that ovulation and menstruation are practically simultaneous. However, although this may be, and probably is, the rule, vet it is far from being an invariable one. Thus, Kölliker, on examining the ovaries of seven women who had

died directly after menstruation, found that in two of the cases there was no fresh corpus luteum in either ovary—that is, no ovum had been discharged at the time of menstruating; and Coste had cited similar instances.

"Ovulation and menstruation may be assumed to occur, as a rule, about the same time, but it is by no means clear what is the precise nature of the connection between the two processes. Authorities differ as to the stage in the menstrual period at which ovulation occurs, tho majority holding that it takes place two or three days before the commencement of the period, while others maintain that it happens at the middle or even toward the end of the period. It is very possible that there is no constancy in this particular respect.

"A still more difficult point remains to be considered. The menstrual decidua is to be viewed as a preparation on the part of the uterus for the reception of an ovum; but it has still to be determined whether the decidua which is broken up and discharged at a given menstrual period is the one prepared for the ovum which is set free from the ovary at the same period, or for an ovum liberated at some previous or subsequent period. The question is one of great importance, as the means of determining the age of human embryos are very materially affected by the answer given to it.

"The menstrual cycle has been seen to consist essentially in a periodically recurring preparation of the uterus for the reception of an ovum. It is important to determine, if possible, at what particular phase of the cycle the uterus is in the condition most favorable for the reception of an ovum. Very different views have been expressed on this point, and two of these call for special notice: (1) That the end of the constructive period is the natural and most favorable moment for the ovum to enter the uterus. (2) That the period of quiescence is the most favorable time. In support of the former view it is urged that the formation of the decidua is unintelligible except on the supposition that it is a preparation for the reception of the ovum, and that the analogy of the rabbit's uterus, in which the sequence of changes is strikingly similar, is in favor of the end of the constructive period, or perhaps the commencement of the destructive period, being the one specially concerned with the fixation of the ovum to the wall of the uterus. It must be noticed, however, that, if the normal time of attachment to the uterus is, in the human ovum, the end of the constructive period -i. e., the commencement of the menstrual period-then it is clear that the ovum which is to be attached can not be the one discharged from the ovary at the same period. For the discharge of the ovum is practically coincident with the onset of the menstrual period, and the ovum, after leaving the ovary, has still, in order to reach the uterus, to travel along the entire length of the Falloppian tube, a passage which is known to take three days in the rabbit and eight to ten days in the dog, and which in all probability takes at least a week in the human species. It follows that decidua which is discharged at a given menstrual period can not have been prepared for the ovum discharged at the same period, but must be the preparation for the ovum which was discharged at the preceding menstrual period.

"The second view, that the period of quiescence in the menstrual cycle is the most favorable time for the entrance of the ovum into the uterus, leads to the same conclusion, inasmuch as the only ovum which could reach the uterus during the quiescent stage is the one discharged at the previous menstrual period. In favor of this second view, that the quiescent period in the menstrual cycle is the most favorable time for the ovum to enter the uterus, the following considerations may be urged: (a) A much greater range of time is given within which the uterus is ready for the reception of an ovum. The quiescent

period is the longest of the four stages which compose the menstrual cycle, lasting from twelve to fourteen days; while, on the other view, that the completion of the constructive process marks the time at which the uterus is best fitted to receive an ovum, the range of time is limited to two or three days at most; and the longer period is more in accordance with what is known of the range of time within which conception may occur.

"(b) The stages in the formation of the menstrual decidua have been compared above with the changes which occur in the uterus of a rabbit from the fourth to the seventh or eighth day of pregnancy; and the close similarity between the two cases has been insisted on. It should now be noticed that these changes in the rabbit occur after the entrance of the ovum into the uterus—i. e., that in the rabbit the ovum enters the uterus while this latter is in the quiescent stage.

"Neither of the above arguments is at all conclusive, and the question is still an open one. It must be repeated, however, that, if either of these views is correct, the same conclusion follows with regard to the relation between ovulation and menstruation-viz., that the decidua of a particular menstrual period is related, not to the ovum discharged at that period, but to the ovum discharged at the preceding period. It follows that there is no necessary connection between ovulation and the occurrence of the menstrual flow, a point which helps to explain the cases quoted by Kölliker, Coste, and others, in which there was no discharge of ova at the time of menstruation. The fact that the two processes, ovulation and menstruation, occur normally at or about the same time, may perhaps be explained by the consideration that at the time of ovulation there is very considerable congestion of the ovaries and Falloppian tubes; and this, owing to the free communication between the ovarian and uterine arteries, must almost necessarily cause congestion of the uterus; and this determination of blood to the large and thin-walled vessels of the decidua is probably an important factor in causing the menstrual hæmorrhage."

These quotations are enough to show the character of the text, and we have only to add that the illustrations are exceptionally meritorious. The book should be studied by all who wish to obtain as clear an insight as possible into the present state of our knowledge of embryology. We would particularly recommend its study in connection with that of Dr. Minot's work on embryology, recently noticed by us.

The National Dispensatory. Containing the Natural History, Chemistry, Pharmacy, Actions, and Uses of Medicines, including those recognized in the Pharmacopæias of the United States, Great Britain, and Germany, with Numerous References to the French Codex. By Alfred Stillé, M. D., LL. D., Professor Emeritus of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania; John M. Maison, Phar. D., late Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy; Charles Caspari, Jr., Ph. G., Professor of Theoretical and Practical Pharmacy in the Maryland College of Pharmacy; and HINRY C. C. MAISCH, Ph. G., Ph. D. Fifth Edition, enlarged and revised in accordance with the Seventh Decennial Revision of the United States Pharmacopæia. With Three Hundred and Twenty Illustrations. Philadelphia: Lea Brothers & Co., 1894. Pp. vi-1903. [Price, \$7.25.]

IMMEDIATELY upon the appearance of the first edition of the National Dispensatory it took a place high in favor with both physicians and pharmacists. The reputation of the men who produced it, together with the intrinsic evidence it bore of their

careful and intelligent labor in its production, caused it to take rank at once as among the foremost books of its class. The succeeding editions have sustained its title to such esteem. It is a subject of congratulation that the late Professor Maisch had practically finished his portion of this revision before he died. The work has been made to conform in every respect to the new Pharmacopeia, and the bulk of what is really valuable in the recent literature of new remedial agents is adequately set forth. The work will undoubtedly meet with great favor among medical men and pharmacists.

## New Inbentions, etc.

AN ADJUSTABLE BRACKET WITH TEST-LENS HOLDERS USED IN TESTING ANOMALIES OF REFRACTION AND THE VARIOUS FORMS OF HETEROPHORIA.

By J. Frederick Herbert, M. D., PHILADELPHIA.

A New and improved apparatus, recommended as a substitute for the heavy, cumbersome test frames now ordinarily used, is intended to be screwed to the wall, the window sill, or the back of a heavy chair.

All physicians who have had experience in using the test frames usually furnished with the test lenses know how much

trouble it is at times to adjust the same on the patient's face; if one ear is higher than the other, then one side of the frame will be too high and the other too low, and very often the patient will complain of the weight upon the nose, especially if the examination is protracted, and each additional lens placed

in the frame only increases the patient's discomfort, which sometimes really amounts to suffering.

Then, again, ophthalmological instruments on stands or tripods are not made rigid enough; there is too much vibration and much valuable time is spent in placing the same in the proper position in front of the patient, and they are also difficult to adjust. Having had these difficulties to contend with, it has been the writer's aim to devise an instrument to overcome some of the objectionable features met with in the instruments used in the daily routine practice of an oculist. The illustration of the instrument with a full description is placed before the profession for their kind consideration.

A is the vertical bar or upright from which extend the arms B and C, fitted into sockets at both extremities, permitting the instrument to be placed in any position, from that of being folded flat when not in use to that of the bars B and C being at right angles, and the carriers D and E parallel to the wall so that the patient can be seated comfortably behind it when in

B is the upper horizontal bar with bearings at the extreme end for receiving the upright, which contains lens holders, etc.

O is the lower horizontal bar similar to B for holding the chin rest. It will be noticed that the two bars B and C are separated throughout their entire length. This is one of the features of the instrument, and the idea is entirely original. This is done to prevent the upper bar from being thrown out of plumb by the weight of the patient's head after the instrument has been properly adjusted and fixed ready for use. It is quite evident that when the chin rest is attached to the same bar as the optical portion of the instrument, the results are vitiated, and we could not depend upon the accuracy of the tests. The two bars B and C are independent of one another, and no matter how much weight is placed on the lower bar, the upper one is not affected in the least, which fact can easily be verified by noticing the action, or rather inaction, of the spirit level.

D is the carrier to which are attached the lens holders, phorometer slide, and small bar with test card holder.

E is the adjustable chin rest fastened by the thumb screw F. F F are the screws holding the parts rigidly in position when adjusted to the proper height.

G are the lens holders, graduated from 0 to 180, similar to a test frame, each containing one revolving and three stationary cells. The outer cells revolve around the entire circle by means of an endless screw and toothed arrangement on the outer portion of the ring (as in the test frame suggested by Dr. Oliver); the three pairs of inner or stationary cells (not shown in the illustration) are also of the standard size for receiving test lenses, plane or rotary prisms, the Maddox rod, etc.

H are the thumb screws for revolving the movable cells, and can be easily handled by either physician or patient in determining the best position or axis when correcting astigmatism, or for placing either cylinders or prisms at any desired angle.

I is the slide or receptacle for the Stevens phorometer.

J is the Stevens phorometer for testing the various forms of heterophoria.

At K there is a hinge by which the slide with the phorometer can be swung into position directly in front of the lens holders (test frame) so that tests for myscular insufficiencies can be made both with and without the correcting lenses.

The thumb screw L adjusts the lens holders (trial frame) G G for interpupillary distances; the bar on which the holders slide is graduated in millimetres and can be used as a pupilometer.

M is the ground spirit level for truing up the instrument

which, as can be seen in the illustration, is placed directly beneath the test-lens holders; this makes the adjustment quite simple and at the same time very accurate.

N is the screw and lever for adjusting or leveling up the lens holders G G.

The bar O, fifty centimetres long, graduated in the metric and inch systems, is brought into use when testing the near point; it is made on a hinge joint; when in position for use it extends directly outward midway between the lens holders, and when not in use it is placed out of the way, parallel with the horizontal arm of the earrier D, as shown in the illustration.

The carrier P slides freely forward and back the entire length of the bar O; it has two sets of clips for receiving cards, test types, and figures for testing the near point.

The instrument is well made in every detail, and is not only of scientific merit, but an ornament to any office, and will at once commend itself to those who appreciate and desire to do accurate work.

This instrument may be obtained from Queen & Co., 1010 Chestnut Street, Philadelphia,

1313 ARCH STREET.

# Miscellany.

Injury by Golf-playing.—In the Lancet for February 10th Dr. A. Symons Eccles gives notes of two cases of gluteal strain in golf-players.

"The first case," he says, "was that of a man, fifty-two

years of age, who came into my consulting room in February, 1893, presenting the usual appearance of a patient suffering from severe sciatica of the right limb-his mode of progression and the posture adopted in standing being at first sight identical with those most commonly acquired by persons afflicted with long-standing painful affections of the sciatic nerve. Supporting himself on two sticks with the trunk thrown over to the left side, the right knee was semiflexed and the heel raised, the toes only being in contact with the ground. He complained of severe pain over the greater part of the right buttock, which was greatly increased by any movement of the right limb, especially aggravated when the weight of the trunk was thrown upon it, as when the left limb was raised in the act of walking. While standing he was careful to throw the whole weight upon the unaffected limb, and could not be persuaded to relinquish the support afforded by the sticks or to attempt locomotion without their aid. On examination I failed to detect any tenderness over the sciatic notch or anywhere in the course of the nerve, nor was there any tenderness about the buttock, save on its upper and outer aspect. Between the anterior superior spine of the ilium and the upper margin of the great trochanter there were distinct tenderness on pressure and apparent swelling. There was also pain of a less severe character in the right lumbar region, which was increased when any attempt was made, whether passive or active, to induce the resumption of the erect posture. No tenderness, however, was elicited on pressure over the lumbar region. On measurement from the point of the second sacral vertebra round the respective buttocks to the median line in front, the swelling on the right side. which I had been at first inclined to regard as only apparent and merely due to posture, proved to be real, as on that side the measurement between the sacral spine and the middle line in front was fifty-three centimetres, the corresponding measurement round the left buttock being only forty-eight centimetres.

The measurements were made as the patient stood supporting his weight on the left limb, the right glutæi being completely relaxed, thus showing that the increased measurement was not due to the contraction of the anterior fibers of the glutæus maximus. On inquiry as to the cause and duration of the pain, the patient informed me that he had, within the previous ten days, commenced to learn the practice of golf, and though, during the first few days, going round the links once daily, he had experienced some general stiffness and soreness at night and in the morning on rising, no localized or severe pain had been felt until two days previously, when, having devoted the greater part of the afternoon to the practice of a stroke involving an attitude and a rapid muscular effort which I am at a loss to describe, but which are no doubt familiar to those who play golf, and desiring to pose in driving a 'tee'd ball' in the most finished style, he felt a violent pain in the upper and outer part of the buttock and over the right lumbar region, so that on leaving the ground he was unable to walk without much suffering and could not maintain the erect posture. At night the pain involved sleeplessness, and no sort of rest could be obtained save while lying on the left side with the back and right thigh propped with pillows. Hot fomentations and rubbing with embrocations had failed to give relief.

"The second case occurred in the person of a member of our own profession, who consulted my friend Mr. Keetley, to whom I am indebted for the opportunity of seeing this second example of the same accident, as he was sent to me for massage of the affected part. I first saw the patient early in April, 1893, when he told me that, as a beginner, on March 31st he was playing golf and went twice round the links, feeling very stiff at the end of the day, especially about the right hip, but not until the evening did he feel anything seriously amiss, when he began to suffer somewhat severe pain about the upper part of the right buttock and lumbar region. As time went on, he felt no better, and was unable to support the weight of the body on the right limb, the trunk being tilted to the left side and the left shoulder thrown forward, the patient presenting somewhat the appearance of lateral spinal curvature, due to faulty posture. The position adopted by this patient when standing and the mode of performing the act of walking were identical with those previously described in the first case. On examination I failed to detect any tenderness on pressure; the whole buttock appeared to be slightly swollen, but the muscles were kept carefully relaxed, any attempt to throw them into action causing pain, especially between the crest of the ilium in the axillary line and the great trochanter, the pain radiating forward toward the anterior superior spine and upward over the right erector spinæ. The measurements from the center of the sacrum to the median line in front over the buttock were-right, forty-nine centimetres; left, forty-seven centimetres. Firm massage of the buttock and loin was administered for fifteen minutes. On April 12th the measurements were-right, forty-eight centimetres; left, forty-seven centimetres. After two or three days' massage the severe pain subsided, though it was not until some days after this that the patient was able to assume the erect posture and to maintain it without painful effort.

"In the first case daily massage of the part for seven days completely restored the patient to the painless use of the affected limb, and after the first four days he was able to walk and maintain an almost erect position, both standing and walking; but the treatment was initiated within twelve hours of the appearance of the local deformity. In the second case, however, there was a lapse of ten days between the commencement of the pain and stiffness and the date on which the patient first saw Mr. Keetley and myself. Owing to the engagements of the patient, he was unable to attend for massage regularly, other-

wise I believe that the pain, swelling, and deformity characteristic of this new accidental malady would have more readily been reduced. The lesion, if so it may be termed, which I venture to suggest existed in these two cases, somewhat akin in their nature and ætiology to tennis elbow, appears to me to consist of a strain and possible rupture of a few fibers of the anterior portion of the glutæi. It will be remembered that the anterior fibers of the glutæi are said to rotate the thigh inward, which is precisely the attitude vigorously adopted at first in making the 'driving stroke.' The aponeurosis of the erector spinæ is suddenly rendered tense when the trunk is rotated upon itself, as the 'driver' is forcibly thrown upward and then backward before being brought down to strike the ball, and it is not difficult to understand how, by the repetition of this exercise on the part of a neophyte, the glutæi may easily become overstrained, even when they are not suddenly called into action to maintain the equilibrium of the player, when, as I believe sometimes happens, in his earlier efforts he fails to strike the ball. It appears to be the habit of some professionals to keep the beginners under tuition constantly practicing certain strokes, not the least important of which, from a golf point of view, being the use of the 'driver,' which is not infrequently broken in the attempts made by neophytes to attitudinize on the model of old and distinguished players."

A Comparison between Chloroform and Ether as Anæsthetics,-At a recent meeting of the Berlin Medical Society, as reported in the Mercredi médical for February 14th, Dr. W. Koerte presented a comparative study of these two anæsthetics. In the course of his researches concerning accidents from the use of chloroform he had found one death in about three thousand cases of its administration. He called attention, moreover, to albuminuria or fatty degeneration of the kidney observed in animals after the prolonged use of chloroform in experiments. Etherization, which he had experimented with in many cases, appeared to him preferable, chiefly by reason of its not producing feebleness of the pulse. In addition, he had found that it hardly ever produced either vomiting or intestinal derangement, so that often on the very day of the operation the patient had been able to take solid food. The author thought that sleep was favored by the previous use of morphine hypodermically, and to that he attributed the fact that the awakening from ether anæsthesia was less disagreeable than that from chloroform anæsthesia. This impression he founded upon what he had been told by patients who had been subjected sometimes to the one and sometimes to the other. Some persons, however, described their sensations at the outset as being more disagreeable when ether was used; it produced a manifest irritation of the respiratory mucous membrane, and it was contraindicated in serious diseases of the respiratory apparatus. On the other hand, it exerted no injurious action upon the kidney or upon the heart. Although fatal accidents might be observed in the course of etherization, they seemed to be more easily avoided than those due to chloroform. In fourteen thousand cases of etherization, Gurlt had not witnessed a single fatal accident imputable to this method of anæsthetization. In administering ether Koerte uses Julliard's mask, with which the air breathed contains always less than five per cent. of ether, less than two per cent. of carbonic acid, and more than sixteen per cent, of oxygen. Anæsthesia is usually produced in about seven minutes, and for this purpose from an ounce to an ounce and a half of ether is required; it can be maintained after that with every appearance of natural sleep by means of a very small quantity of ether, so that generally the total amount consumed in an operation lasting half an hour is not more than three ounces. In the rare instances in which anæsthetization

March 10, 1894.]

with ether is retarded the addition of about twenty drops of chloroform is sufficient.

Water in the Treatment of Scarlet Fever.—Dr. John H. Carslaw, of Glasgow, contributes an article entitled On the Severer Forms of Scarlet Fever, with Special Reference to Antipyretic Methods of Treatment to the February number of the Glasgow Medical Journal.

"With regard to the external use of applications of cold and tepid water," he says, "I hope to have shown:

"1. That in the large majority of cases they are not required.

"2. That even in simple cases and in anginous cases tepid spongings are useful in allaying restlessness and giving comfort—if the rash has not developed, the addition of mustard being an advantage.

"8. That mustard spongings are particularly useful during the earlier stages of an attack in which nervous phenomena are prominent.

"4. That for the hyperpyrexia of such (nervous) attacks, especially if the rash has developed, repeated cold wet packing is a convenient and efficacious method of treatment, general improvement often following its use.

"5. That local applications to the head may sometimes be of assistance.

"6. That in all cold applications there is need for the exercise of the greatest care."

Should Civilization Suppress Quackery ?—The Hospital, an English journal, prints the following:

"Unlicensed medical practice either makes for the public good or it does not. By this standard it is to be tried; and by this standard it will, in the long run, either stand or fall. As medical men, we have no taste for 'kicking against the goads'; and as educators of public opinion we accept the challenge thrown down to us by a portion of the public, and we defend this general position: that only men of special education and training are competent to deal properly with bodily diseases. If this position can be successfully maintained, it follows in the strictest logic that only men of special education and training should be allowed by law to practice the medical art or any part of it. The mere penalizing of the unlicensed use of medical titles is a delusion and a snare.

"One might naturally suppose a priori that no intelligent person would think that a practitioner without special training could be as competent as a practitioner with special training. But in actual experience we find that a considerable percentage of the population put their trust in persons who have had no medical training. Now, we can not at any length argue this point here, for want of space, although we think it is well worth arguing. But let us put a single case which will illustrate the whole position. There are in Central Africa medicine men, rain-makers, witch doctors, and the like. Would any sane English man or woman think of putting himself under the care of such persons in a dangerous illness if an English doctor were at hand? Most assuredly not! But why not? The sole reason is that the African has no certain knowledge, and therefore no assured skill. The white doctor has knowledge, and therefore skill. It is the possession of proved knowledge and skill, and that alone, which makes the white doctor trustworthy as a doctor. It is the want of such proved knowledge and skill which makes the savage dangerous. But in this country a person who has had no medical education is necessarily as ignorant of medicine as the African witch doctor, and in many cases even more ignorant. An untrained man who practices medicine is likely to know much less of his art than an untrained man who practices law, and for this reason: the things con-

nected with a knowledge of the law are to some extent a part of everybody's general education. But anatomy, pathology, chemistry, the medical art—none of these constitute any part of general education. So that for practical purposes any man who has had no special training for medicine is just as ignorant of the art and science which he essays to practice as if he had no education of any kind; just as ignorant, in short, as the Central African medicine man. This illustration may stand as a sample of the line of argument which should be addressed, not indeed to the intelligent public, but to that portion of the well-meaning public who, with the most peculiar mental perversity, insist that for life-saving purposes a lifeboat which has been specially built to float in storms is not so trustworthy as a washing tub would be, which is not a boat at all."...

"Now, if a business is such that its managers are afraid to expose it 'to the full light of day'; if, moreover, it is such that 'no honest man' can have anything to do with it, can it be for the interests of the public that such a business should be allowed to be carried on? Let it be remembered that these are the conclusions of a man who is not in a position to form a really competent opinion of the medical aspects and dangers of the business. They are the opinions of an educated man of fair mind on the broad and non-technical aspects of the case. In plain words, quackery, in its most favorable form, has been declared by this fair-minded magistrate to be a thing which will not bear exposure to the 'full light of day,' and a thing of which 'no honest man can approve.' If scientists and medical specialists, who alone can see the thing in its true and dangerous light, had been sitting in judgment upon the case, terms of condemnation very different from these would have been truthfully and properly employed.

"But if quackery in this favorable form be condemned by all right-minded men, what is to be said of it when practiced on the poor and ignorant by unscrupulous persons who have not merely no knowledge of medicine at all, but who are destitute of that general mental capacity and common sense which enable a man to minimize dangers and to practice the scoundrel's trade with a minimum of scoundrelism? There is only one thing to be said by men who recognize the logic of facts; Quackery ought to be stamped out. A quack medical practitioner is much more dangerous than a mad dog. The law encourages the suppression of mad dogs; it does not, as it now stands, encourage the suppression, but the increase of quacks.

"Now let us come to practice. If unlicensed medicine is to be stamped out, who is to lead the way in its suppression? The medical profession undoubtedly. It is mere folly to suppose that lawyers will initiate reforms in the laws which regulate medicine. We ourselves must do that. Loyalty to the State imposes upon us the obligation of uprooting and destroying everything which makes against the health of the state. If it be asked what class of medical men are to undertake this duty, the answer is that the General Medical Council is under the most absolute obligations to lead the way. That council takes no steps, however, and therefore the whole body of practitioners must organize Aoluntary societies to effect such alterations in the law as the necessities of the case demand. Of course a certain amount of unpopularity will fall to the lot of any medical man or medical organization which takes up this line of action, and base motives will be imputed. But is a man or a profession to be deterred from plain duty by the fear of the imputation of unworthy motives? When political Liberals demand reform, somebody is always ready to assign base motives. When Unionists stand for the Union, somebody else sees the cloven hoof of base motives. But does any man, who is a man, hold his hand for that? The medical profession is very timid, and very ready to run away from shadows. That

is a kind of cowardice entirely unworthy of educated men, and especially of Britons. The plain duty of doctors is to check and uproot all kinds of ignorant and unscrupulous medicine which endangers the public well-being, and that duty they must rise and do or confess themselves unfit to carry the status and name of Englishmen."

A Medical Building.—To meet the requirements of many members of the medical profession, it is proposed to erect an improved office building in the central part of the city. The plans have been designed with special reference to the needs of the tenants, who are to be exclusively members of the medical profession or engaged in occupations directly associated with medical practice, and no office will be rented to any tenant whose standing in the profession is not entirely satisfactory. The location will be convenient to the Grand Central Depot, the Fifth Avenue stages, the Third and Sixth Avenue elevated roads, the Madison Avenue and Sixth Avenue surface lines, and the Forty-second Street crosstown cars.

It will have every convenience and practical facility for the accommodation of tenants, such as telephones, a telegraph office, a district messenger service, an agency for trained nurses, mail chutes, pneumatic tubes, steam heat, electric light, electric motor power, etc.

The elevators will be especially large and smooth-running, and the access to each floor will be also had by means of easy stairs.

The best of janitor service will be furnished, and wheeled chairs will make it practicable for an invalid to be conveyed from a carriage to the elevator and thence to an office in any part of the building with greater facility than a lame or feeble person can now enter an office in an ordinary house.

The building will be thoroughly fireproof and will be finished in the most attractive manner. On each floor there will be separate retiring rooms for gentlemen and ladies. The ground floor will be occupied by stores, which it is believed will be very desirable for apothecaries, instrument-makers, opticians, etc. There will be hot and cold water in every office, and all special conveniences will be arranged to suit tenants reuting space in advance. All wiring for electric motors, etc., will be done when the building is erected, so that subsequent expense for such improvements will be unnecessary. The rents will pay for janitor service, heating, and lighting, and will be very moderate in comparison with the rents now paid by physicians for ordinary offices, without the advantages of location, facilities, motor power, attendance, association, etc., which will be secured in the proposed building.

The facilities so difficult for specialists to obtain in flats, boarding houses, and ordinary residences will be at hand in every office in the building.

Resection of the First Metacarpal Bone. - The Lyon médical for February 11th gives a summary of a Lyons thesis by M. P. Marlier, a pupil of the École du service de santé militaire. The author has been able to collect only three cases of this operation. One is attributed to Dr. Martin, of the Palatinate, in which there was a chondroma of the bone. In the two other cases, which occurred in Professor Poncet's clinic, the bone was resected by that surgeon on account of diffuse inflammatory lesions. The remote results of this operation have been studied by M. Marlier, who has been fortunate enough to fall in with M. Poncet's patients several years after the operation. The conclusions are as follows: When it is judged necessary on account of the gravity of existing lesions, extirpation of the first metacarpal bone is a good operation from the functional point of view. The general appearance of the hand is not very much changed. Of course the thumb, being carried back to the car-

pus, is just so much shortened, but it maintains its habitual usefulness in prehension, and for any manual work that does not require the employment of great force it is as serviceable as an ordinary thumb. If the tendons have been managed carefully, it preserves all its movements, but they are limited, at least apparently, and diminished in power. It has been observed that the force with which the thumb can be made to oppose the fingers is two thirds of that of a sound thumb. Whatever the patient's age may be, regeneration of the metacarpal bone can not be counted upon. The base of the phalanx comes into immediate contact with the trapezium, or is separated from it only by a few fibrous shreds. Although this failure of regeneration is to be regretted from an æsthetic point of view, it does not appear to compromise the functions of the digit. Since removal of the first metacarpal bone gives ultimate results so perfect, it may be assumed that simultaneous resection of this bone and of more or less of the neighboring bones is preferable to amputation. In one of M. Poncet's cases, believed to be unique, one of extirpation of the first metacarpal bone and the first phalanx, a rapid cure occurred in spite of the patient's comparatively advanced age. According to the accounts received, the digit maintains its utility. The same is true of a case of complete removal of the bones of the thumb reported by the author. The case was one of simultaneous removal of the first metacarpal bone and of the two phalanges of the thumb, in a young man, for acute infectious osteomyelitis with detachment of the epiphyseal periosteum.

The Antiseptic Treatment of Burns.—In the Centralblatt für Chirurgie for February 17th we find ana bstract of a Paris thesis on this subject by Madame (or Mademoiselle) Nageotte. After a very interesting historical introduction concerning the methods formerly employed in the treatment of burns the authoress states that the best results possible are attained by maintaining an aseptic condition of the wound. She says that, especially in very painful burns, it is best to employ general anæsthesia, in order that the application of the antiseptic process may not be interfered with. After the wound has been rendered aseptic she endeavors, wherever it is possible, to procure its healing under a dry dressing, whether the burn is of the first, the second, or the third degree, and uses as disinfectant agents iodoform, thiol, ichthyol, and particularly bismuth subnitrate as recommended by von Bardeleben. She adds histories of forty-five cases.

Mercurial Ointment in the Treatment of Erysipelas.—
In the Medical Reporter, of Calcutta, Dr. A. S. Sandel says that he has recently employed mercurial ointment in a case of erysipelas with extensive sloughing of the integuments of the chest and abdomen, after free incision and the usual constitutional treatment had proved insufficient to arrest the progress of the disease. Its use in this case was attended with such decided advantage that he determined to give it another trial as soon as a favorable opportunity occurred. Within three weeks a similar case came under his observation. The patient was an Ooriah and rather aged, but he recovered under the treatment. The ointment was spread on fine linen, and with that the whole of the inflamed surface was kept covered. It was not applied on the open sores.

Bilateral Congenital Absence of the Radius.—At a recent meeting of the Leipsic Obstetrical Society, according to the Centralblatt für Gynäkologie, Dr. Krönig showed a newborn child which was the subject of this defect of development, and remarked that in all literature there were only forty-five cases of entire absence of the radius recorded, and in only twenty-one of these was the defect bilateral.

# Rectures und Addresses.

#### MODERN EXPERIMENTAL MEDICINE.

ANNIVERSARY DISCOURSE, NEW YORK ACADEMY OF MEDICINE, November 29, 1893.

By WILLIAM H. THOMSON, M. D., LL. D., PROFESSOR OF MATERIA MEDICA AND THERAPPUTICS AND OF DISEASES OF THE NERVOU'S SYSTEM, UNIVERSITY OF THE CITY OF NEW YORK.

(Concluded from page 294.)

There is still another wide field in medicine which falls to the chemist. The living body is constantly generating poisons of its own as it lives. To remove these is the business of the excreting glands. But it is now known that certain great organs have the conservative function of destroying or neutralizing some of these self-generated poisons. Thus it is maintained that poisons are generated every day of our lives in natural digestion in the intestine which, if they were not properly dealt with by the liver and other organs, would quickly kill us, chiefly by their poisonous action on the nervous system. We seem to have here a promising clew to the origin of many neuralgic, convulsive, or paralytic functional disorders, and therefore to indications for their treatment, to determine which we are to look to the progress of chemical discovery.

Such being the different lines on which modern experimental medicine is pushing its investigations, the outlook for material gains in the next twenty-five years is fully justified by the splendid showing of special equipment for the purpose which the whole field of medicine now presents. Thus Italy, long ago the mother of medical schools for Europe, has recently, and almost suddenly, come to the very front again in her contributions to experimental medicine. One of the services of the young Italian school of investigators has been the following up of the great discovery of the French surgeon, Laveran, in Algiers, of the blood parasite which causes the ague disease or malaria. They have good opportunities in Italy for such a study, and the work of Marchiafava, Celli, Camillo Golgi, and others in this field is fully confirmed by Sternberg, Councilman, and Osler in this country, by Professor Vandyke Carter and Professor Evans in India, and lately by the important work of Dr. P. Hehir, lecturer on pathology in the Nizam's medical school, Hyderabad, India. Here in our New York hospitals we are also equally confirming the connection of ague with these blood parasites, the microscope thus aiding both our diagnosis and treatment.

The chief interest, however, of Laveran's discovery is not only in demonstrating the nature of one of the chiefest causes of what we call unhealthy places, countries, or climates, but that a new world is thus opened to us in the microscopic kingdom of life itself. For the malarial organism is not a bacterium or vegetable parasite, but in its nature is an animal organism, or amceboid protozoon, as it is called. If that be so, it can scarcely be the only one of its kind. In fact, the discovery of disease-producing micro-

scopic amœbæ is multiplying fast. Thus a peculiarly intractable and fatal form of dysentery is now demonstrated to be caused by a special amæba. But one of the most curious developments of the kind has been demonstrated in our own country as the cause of the Texas cattle plague. We may remark that the infectious diseases of animals are rightly regarded of as much significance as those of our own species. Thus the humble rabbit is now the object of the greatest interest and study to investigators in Naples, Berlin, Jena, Paris, Dorpat, London, and Glasgow, because it is infested by a very minute parasite, evidently not a bacterium, in the living cells of its liver ducts, and all this interest in the rabbit is because we may thus find out what cancer is. Now, in the case of the Texas cattle fever it is now demonstrated beyond question that it is caused by a protozooid parasite which enters and destroys the red blood-corpuscles of the cattle, reducing them from seven million to the cubic millimetre to two million, and in the same manner that Laveran's protozoon enters our red bloodcorpuscles. But the further extraordinary fact has been demonstrated that the Texas protozoon gains entrance to the bodies of the cattle by means of a Texas species of cattle tick, for ticks which infest cattle in our Northern States never produce this fever. This death-dealing cattle protozoon, therefore, must live first on ticks as its host, and from the ticks pass to the larger animal. Now, Livingstone first made the world acquainted with the formidable tsetse fly, whose bite destroys all bovine animals in certain localities in Africa by a slow wasting fever like the Texas cattle fever, and the mystery of its action-namely, that one such insignificant fly can kill an ox-may perhaps be found to be due to a similar infection to that of a Texas tick.

Thus this subject of animal protozoa is looming up in proportions which make us feel like the English naturalist Bates, when he had been working for eleven years in the vast Amazon forests, that the field seems to have neither beginning nor end. In fact, it seems to begin in our own blood in the case of our vast host of white corpuscles, which act very much like independent amæbæ or animals within us, whose business it is to eat up whatever should be eaten because it is growing old, or because it has no business to be there. Hence they are called phagocytes or eating cells, and Dr. Hehir thus describes how he watched a white corpuscle catch an actively moving malarial parasite: The phagocyte first advanced toward its victim, and then for about ten seconds appeared inactive, barely touching its prey, and almost suggesting that it came to make friends with the unwary parasite, reminding one of the spider and the fly. That portion of the parasite in contact with the white corpuscle was apparently stationary, while the rest of it was making lively efforts to set itself free, but gradually its movements became imperceptible. The phagocyte continued to entangle its prey, until within the space of a minute it completely incorporated the amœboid parasite within its protoplasmic web, whence there was no exit. (Lancet, May-28, 1892.)

But to return to the Italian school of experimenters,

who are largely disciples of instructors from beyond the Alps, such as the veterans Hugo Schiff, of Florence, and Moleschott, of Rome. Following up the discovery of the tetanus bacillus by Nicolaier in 1884 in Professor Flügge's laboratory at Göttengen, but which was first isolated in a pure culture by the celebrated Japanese bacteriologist Kitasato in 1889, the Italian investigators, Tizzoni and Cattani, developing Kitasato's suggestion, have succeeded in isolating an antitoxine to lockjaw from the blood of rabbits, which has been successful (in 1892) in eleven cases of severe tetanus in men, and with such promptness that no doubt of the curative efficacy of this remedy can be further entertained.

Crossing the Alps to the great medical center of Vienna, we have a striking example of the advantages of associated medical investigation carried on in the same building. In the Vienna Pathological Institute we have first the chemical laboratory under Ernst Ludwig, to which is committed by the Imperial Board of Health all questions about the pollution of drinking water and like public questions. Then the famous pathological laboratory founded by Rokitansky, and the laboratory for experimental pathology under the superintendence of the veteran Stricker, while in another building is the physiological laboratory of Professor Exner, well known for his work on cerebral localization, and the bacteriological laboratory under Weichselbaum, whose name is associated with the bacteriology of pneumonia. All these departments, liberally furnished by the Imperial Government with funds for the prosecution of original experimental research, cooperate together, each referring to the other any questions which may arise that call for a special report from its proper laboratory. In fact, Germany is the richest country in the world in laboratories of experimental medicine, with the result that she surpasses all other countries in her contributions to medical knowledge. Of the spirit of cooperation in this work and of its singular extent we need only cite, for illustration, the fact that the list of editors of the Archiv für experimentelle Pathologie und Pharmakologie contains the names of two professors of Leipsic, one in Munich, three in Giessen, one in Halle, two in Prague, four in Königsberg, one in Zurich, two in Marburg, two in Berlin, one in Göttingen, one in Erlangen, one in Berne, one in Kiel, one in Greifswald, one in Dorpat, one in Frankfort, and three in Strassburg.

Such a list, however, only represents a fraction of the number of zealous experimental investigators in a country abounding with every kind of laboratory for every kind of medical research. There is, however, one aspect of this subject which we must very briefly refer to, suggested by an appeal which I have received and which I suppose that others present may have likewise, from a society in London, apparently looking toward the formation of an international association for the suppression of all medical experimental laboratories, on the ground that they are little else than revolting establishments for cruelty to dumb animals. Now, it does not do to treat this serious subject with levity. It is no adequate answer merely to say, what is nevertheless the truth, that more animal suffering occurs daily at our slaughterhouses from which both vivisectionists and anti-

vivisectionists get the meat for their tables, or to insinuate that the collation after the adjournment of an antivivisection society testifies to more barbarity in its lobster salad than ever happens in Koch's whole building, because the unhappy crustaceans therefor were carried alive from their cool marine beds to be soused alive in boiling water. The real question is, What is cruelty? If simply killing animals is cruelty, then every hunter for the sport of the thing is a monster thereof, and buying butcher meat is patronizing and sharing in cruelty. All Nature, then, is Satan's kingdom from the beginning, and no one else's. The line should be drawn just here. Inflicting suffering per se is not cruelty; only unnecessary suffering so inflicted is. This principle is impregnable, for no one can live in this world without inflicting suffering, and none but hypocrites can deny that statement about themselves. The question, then, is not that of inflicting suffering, but for what purpose is it inflicted? That being so, we can strongly affirm that the intent of scientific men in experimenting on animals is so much the reverse of cruel that they may be trusted to devise the lessening of suffering in their work much more than ordinary butchers do in theirs, and as we allow these latter to kill in order that we may eat, we may let the men continue to work for the lessening of human sorrow and death, who already by that work have reduced, for example, the puerperal-fever mortality in the Vienna maternity from twenty-eight per cent. to one third of one per cent., who are saving now fully fifty thousand lives yearly in the field of surgery, and who bid fair to rid the world of all its epidemics as well as many of its hitherto greatest causes of suffering and death.

In illustration of this particular subject, and of our whole subject, we may give a short account of what a complete experimental medical institution is, as shown by the newly opened Koch Institute for Infectious Diseases in Berlin. Next to the new Infectious Diseases Hospital buildings, which have every arrangement for the isolation, treatment, and sanitation of the sick, is the Scientific Division building, a triangular structure, well lighted on all three sides. On the cellar floor on one side are the receptacles for the fodder or food for the stock of animals and the quarters for the animals themselves, whose cages are warmed by Kauffer's mantel ventilating heaters, which in winter force in a constant supply of fresh air. The rest of the space of this floor is used for an electro-motor, a water-distilling apparatus, a workshop, and for some of the heavier chemical apparatus. the next floor are the rooms of the inspector and the assistant physicians who attend to the observations on the animals on whom experiments are being made, those already inoculated, etc., which are there in the compartments assigned to them, each cage having a card with the manner and time of treatment of its occupant. The next floor is used for bacteriological studies; at the apex of the triangle are the workrooms of Robert Koch, then those of his assistants. These rooms are all furnished alike with a work-table and its appurtenances at its center, while at the large windows are the tables for working with the microscope, with every contrivance for lighting the microscope

stage, with a digester, chemical reagents, and tools within reach. In each room there is a gas stove with its incubator for bacteria, having a thermometer so connected with electric wires at the two points of desired maximum and minimum temperatures that a bell is rung automatically whenever either heat point is reached. On this floor is the large incubating room, made on the model of that in Pasteur's Institute, being a room within an ordinary room, lit by electric light, and whose ceilings, walls, and floors are of different non-conducting layers of wood, brick, and clay, and the whole interior lined with lead to keep the heat confined. The entrance to the room is by means of a double set of doors so arranged that the outer door must be closed and locked before the second door can be opened at all. On the walls are the leaden brackets for holding the cultures of bacteria. The heating of this room by hotwater pipes is automatically regulated by electric wires and bells so that the temperature never goes below 37° C. or above 40° C. On the next floor is the chemical laboratory, with rooms for the chief of that department and of his assistants, with all their requisites for work. Also the department for microphotography, with its full apparatus, the dark room of this laboratory having its floor cemented and varnished for further insuring against the defilement of dust. Lastly, on the next floor comes the library, that most indispensable adjunct of experimental medicine in these days of incessant publication of researches from Japan to America, and where we may be sure there are no dusty

If the ancient Greeks, among their gods for every quality, had a god for accuracy, they certainly would have erected his image over the portal of such a temple as this, Everything here is devised under the inspiration of that quality. The attending priests have to go through ablutions and washings of utensils which would have worn out the most scrupulous observer of the rules in Leviticus. It is curious, indeed, to read in the old Mosaic injunctions that leprosy might so infect the walls and plastering of a house that the priests had the right to condemn it and order the house to be taken down (Leviticus, xiv, 33-49). The modern discovery, therefore, that the bacillus of leprosy closely resembles the bacillus of tuberculosis might be commended to some modern critics as another proof that the old Egyptian priest Moses could not have written the Pentateuch, but that it is a very recent book indeed,

Time forbids us to more than mention that great center of experimental medicine, the University of Dorpat, in the German Baltic provinces of Russia. For years the reports of its physiological laboratory under A. Schmidt and of its chemical laboratory under the veteran Dragendorf have been widely known in the world of medicine; and of their younger colleagues, Professor Thoma stands in the front rank of bacteriologists, while the recently published work of Professor Kobert on the action of drugs as interpreted by experiments is generally received as the most authoritative work in its department.\* In St. Petersburg

itself the new Imperial Institute of Experimental Medicine, erected by the government and by the munificence of Prince Alexander Petrovich, who is its curator, is the largest establishment of the kind in the world. It includes no less than eight large buildings, and nothing has been spared to make it equal to Koch's Institute in Berlin and the Pasteur Institute in Paris. With the efforts made to fill its chairs with the most eminent professors who can be secured, there can be little doubt that it will soon be another of the great centers of scientific activity. In Sweden the ancient University of Upsala is known to all physiological chemists by the work of Professor O. Hammersten. In Norway Professor Lochman's laboratory at the University of Christiania is one of the resorts of English workers in original research, who till recently were denied such opportunities for prosecuting these investigations in their own country.

France is second only to Germany in the field of experimental medicine. Thus the English student of bacteriology has to learn the two languages, French and German, if he is to keep up with the subject at all. It is to France, indeed, that we owe the real beginning of our knowledge of the true relations of the invisible earthly world of life. Never in the history of human knowledge has it been given to one man to make a greater addition to it than that contributed by Pasteur. One can not help feeling a glow in reading the words addressed to him on his salutatory which describe how, beginning with his researches on fermentation with the lactic-acid-making yeast, he went on to the agents which produce putrefaction of animal substances, which he showed was a strictly analogous process with fermentation, till he came to this memorable conclusion: that "whenever and wherever there is decomposition of organic matter, whether it be the case of an herb or an oak, of a worm or a whale, the work is exclusively done by infinitely small organisms. They are almost the only agents of universal hygiene, as they quickly clear away the remains of all that has had life. They protect the living against the dead. They do more. If there are still living beings, if since the hundreds of centuries the world has been inhabited life continues, it is to them we owe it."

It is the Pasteur Institute in Paris that has been the model for all other institutions of experimental medicine not only in France, but also in all the world. The impulse to prosecute experimental researches has extended to every large hospital and medical school in the country, and the published researches of Gamaleia, Telamon, Roux, Yersin, Chauveau, Koga, Bouchard, Gautier, with the naturalized biologists, Metschnikoff and Soudakewitch, and a host of others in every department, show how well France maintains her old place and rank in the world of practical science.

The profession in Great Britain has been long fettered by legislation hostile to all forms of experimental medicine which involved experiments on animals. It is a curious chapter in history, with many of the features of a religious crusade. But now that the British public is learning better what sort of beings physicians are and what their aims are —namely, to spoil their own business as much as possible by preventing disease—English investigators are no longer

<sup>\*</sup> To the abiding disgrace of Russia, this great university has been suppressed this year because it was German.

obliged to go to foreign countries, but can work at home in London at the Conjoint Research Laboratories of the Royal College of Physicians and the College of Surgeons, at the bacteriological laboratory of the College of State Medicine, and at the Brown Institution, where experimental physiology and pathology are carried on. Besides these, there are physiological and pathological laboratories at University College, King's College, Guy's, St. Thomas's, St. Mary's, and Charing Cross Hospitals. At Cambridge there are the physiological and pathological laboratories of the university, and also at Owens College, Manchester; at Oxford, a physiological laboratory only. The University of Edinburgh is well supplied with laboratories in physiology, pathology, bacteriology, and sanitary science, and the Royal College of Physicians of Edinburgh has established its research laboratory. In Ireland, Queen's College, Belfast, has both physiological and pathological laboratories. This new movement and the former impetus from the continental schools have already borne good fruition. We may simply mention in illustration Gaskell's researches on the contracting, expanding, and conserving rôle of accelerating and of inhibiting nerves; McKendrick's on the gases of the blood; Macalister on the physiology of heat production; William Hunter on pernicious anæmia and on the physiology of the destruction of blood corpuscles; Sidney Martin on the blood poisons of diphtheria; and the important contributions to the physiology of the nervous system by Ferrier, Horsley, Beevor, Schaeffer, and others. The younger school of British bacteriologists is also rapidly assuming its proper status, as was shown in the important debates last year at the London Pathological Society and at the British Association on the subject of immunity. Lastly, to the illustrious Sir Joseph Lister the whole world is indebted for his early appreciation of the bearing of the immortal discoveries of Pasteur on surgery, and his triumphant demonstration of their practical application in the new surgery which will ever make the nineteenth century memorable in the annals of medicine.

In the field of experimental medicine our own America has shown hitherto that she is a new country in more than one sense. It would seem to be the fashion with many to praise whatever is new and depreciate whatever is old on principle. But we might as well prefer new wine to old as to welcome perfect newness in education, literature, or science. There was much that was crude enough in the medical education of the United States of twenty-five years ago. To get an adequate medical training, the tide of emigration had to be reversed and Americans had to go East. A better era, however, is now fairly begun. We have three laboratories in this city alone in which medical research is and can be carried on in either one of them with much better facilities than could be found in all America twenty years ago. But the laboratories of the College of Physicians and Surgeons, the Loomis Laboratory of the University, and the Carnegie Laboratory of the Bellevue Hospital College are things of yesterday, and yet already the work of members of this academy therefrom is now quoted and appealed to in the litera-

ture of the world's scientific brotherhood, a rare occurrence in former times. Meantime Johns Hopkins University has attained a foremost rank among the institutions of the world for original research, while the laboratories of Harvard, Yale, and Pennsylvania Universities, and of the University of Michigan, are each new centers of medical investigation, which bid fair to represent our country as she should be represented in the field of modern science. Our medical colleges, however, have been at a great disadvantage in comparison with similar European institutions, in that they have been so largely private institutions, with no support or recognition from the Government or even from the general public; and when they have been associated in name with academic colleges, the connection has often been anything but integral or organic, more as if they corresponded to an appendix vermiformis, which might easily be cut off without being either missed or regretted. It has been therefore mainly by private munificence, but lately given in any case, that America has been able to take a position in experimental medicine at all, and yet we can already point to such names as Welch, Councilman, Sternberg, Prudden, Byron, Wood, Chittenden, Vaughan, and others as men for us to be proud of.

Rather unexpectedly to some, the municipal government of the city of New York is to be credited with one good thing, and that not a small one. I bespeak here the full appreciation and co-operation of the academy and of the profession of our city in the work of the health board, under the supervision of Dr. H. M. Biggs, for the early diagnosis of diphtheria by bacteriological methods, for which he has devised a simple and effective system, which enables any practitioner to send an inoculation of his own from the throat of a suspected case to the health board. bacteriological laboratory, and to have the diagnosis settled within twelve hours. The practical value of this system is great, for every physician knows that we ought to have no doubt about a throat exudation in any case, for true diphtheria is always dangerous, not to the patient alone, but to everybody, and yet in many instances only a bacterial cultivation will give certainty to the diagnosis. Moreover, diphtheria does not always disappear with the membrane, for enough of it may remain to both inoculate a culture plate and to infect others, when only nasopharyngeal mucus is present to inspection, and such children may be allowed to play with others or go to school, with the most fatal results. Dr. Biggs has charts which by the graphic method conclusively demonstrate how single cases of diphtheria have started neighborhood epidemics in our city, just as a fire caught in a room spreads first to other rooms and then to surrounding houses; and this valuable work should lead to dealing with this fell disease by resorting to the same measures for removing and isolating the sick, till all its germs are known to be gone, that the community now allows to be done by law with small-pox.

'In conclusion, we protest against a word of what we have said about experimental medicine being construed as depreciating either clinical medicine or pathological anatomy. Showing the fine fruit on one branch of a tree certainly detracts nothing from the excellence of the fruit on

the other branches. More than that, experimental medicine never can be a substitute for clinical medicine. We might as well fancy that microscopes are going to be so wonderfully improved that they will not need eyes to see through them. Experimental medicine is but a new handmaid to clinical medicine, coming now just at the right time to aid us at the bedside toward clearer diagnosis, clearer appreciation of conditions, clearer prognosis, and last, but not least, to less empirical and to more scientific treatment.

Secondly, it is time that the general public should appreciate how universally beneficial all progress in medicine is to the rich and to the poor alike. Medical science knows absolutely no distinctions of circumstance, age, sex, culture, or brain. All fall sick together, and all have the same claim to be kept from falling sick, or to be helped if they do. Is it too much then to hope that in the coming century a small fraction-for that is all that we would think of asking-of the public money now spent on ironclads, for example, with apparently the result of showing how well they can sink, will be given to our workers, to enable them to rid the world, say, of malaria? Why, even real estate men might subscribe toward such an object, as a mere matter of land speculation. Seriously, our generous donors, following the example of that practically minded man, William H. Vanderbilt, should consider whether they can not as wisely contribute of their wealth to institutions which will fit men to make accidents to limb and body less formidable, or who will smite pestilence by day or by night, or who will lessen bodily suffering in too many ways to recount, as to go on endowing colleges for undergraduate boys.

Lastly, I take my leave with many apologies for such a long discourse, by saying that this review emphasizes how truly international the brotherhood of medicine is. Fancy an attempt nowadays to have the law-makers of the world co-operating together, legislators in England comparing notes with the councilors of the Czar, and receiving suggestions from each other! But harder yet is it to conceive of co-operation between Rome, St. Petersburg, Tokio, Edinburgh, Boston, and all other places between, in questions religious! But in medicine we do not even know about one school of doctrine or another. From the nature of the case, ours is a worldwide, zealous partnership, all working together on equal terms for one end, and inevitably that end will come to pass in a world made by medical men much the happier, because much the healthier.

#### DIPHTHERIA.\*

By JOHN A. LARRABEE, M. D.,

LOUISVILLE, KY.,
PROFESSOR OF DISEASES OF CHILDREN, HOSPITAL COLLEGE OF MEDICINE.

It would require a great deal of time to enumerate the remedies which have been proposed and advocated for diphtheria. Suffice it to say that nearly every drug in the

materia medica has been employed, and to each has been accorded a degree of success backed by the enthusiasm of the author. I shall only attempt at this time to mention such agents as have, in my hands, proved worthy of further trial and are entitled to your consideration.

As I have often told you, when speaking of the eruptive diseases, there are cases occurring every now and then in which no treatment is of any avail, in which all remedies fail, and which go on to certain and rapid death, in spite of the most approved methods. A large allowance must therefore be made for the character of the epidemic in summing up our successes. In other words, you will sooner or later discover that there is such a thing as diphtheria and diphtheria.

The treatment of diphtheria should, in view of its pathology, be both local and constitutional, and both should be commenced at the start and pushed vigorously to the end.

And just here I am tempted to give you some rules which have become axioms with me:

- The local manifestations are not always in proportion to the gravity of the disease. Often a comparatively slight extent of membrane is followed by the most profound toxemia, and on the other hand very extensive pultaceous, oyster-like sloughs produce little or no constitutional disturbance.
- Anæmia, albuminuria, and enlargement of the cervical and parotid glands are to be considered, as marking the extent of the systemic involvement and as precipitating cardiac failure.

Cateris paribus, the danger of blood poisoning and laryngeal complication is in proportion to the continuance of the local manifestations. For this reason it is of prime importance that the false membrane and infecting slough should be removed by agents which are harmless to the sound tissue. The latter is an important consideration, as there are very many chemicals which will remove the false membrane but which are also capable of doing violence to the healthy mucous membrane. Patients who are old enough to properly use a gargle will be greatly benefited by the peroxide of hydrogen properly diluted and alkalinized. Much of the discredit into which this wonderful and powerful agent has fallen is due, in my judgment, to its improper use. In infants and young children all attempts to dislodge the false membrane by gargles, sprays, and mops will prove futile, and the enforcement of such a plan soon becomes cruelty. The introduction of the wonderful vegetable ferment known as "papoid" by the enterprising pharmacists Johnson & Johnson has proved to be a great blessing. It has certainly done yeoman's service in my practice. Indeed, I may say that it leaves little more to be desired in the local treatment of diphtheria. To be effectual it must be used by insufflation, which plan is the most acceptable as well as the most effectual in children. A fine and almost impalpable powder should be made by triturating "one part of papoid with two parts of boric acid or bicarbonate of sodium."

This powder is placed in the chamber of an "insufflator," the tongue is then depressed by a spoon handle and the bulb of the insufflator is suddenly compressed and the

<sup>\*</sup> Extract from a lecture delivered at the Hospital College of Medicine, Louisville, Ky., November 17, 1893.

powder is thickly deposited over the tonsils and fauces, every part being reached. This operation should be repeated at intervals of an hour until the membrane becomes pultaceous and is easily expectorated. Fluids should not be allowed for a few moments afterward. By cutting a hole in a rubber ball and inserting a glass tube or cylinder of elder wood, an insufflator may be improvised in any farmhouse in the country. The crying and resistance of the child only serves to better expose the pharynx and make the distribution more thorough. Of course, some of the powder will be swallowed, which is no disadvantage and may possibly assist in the digestion of food which is impaired by high temperature. Internal treatment should be directed from the very inception of the disease to the preservation of the integrity of the blood corpuscles and the elimination of the poison. For this purpose no better treatment will ever be proposed than the administration of the muriated tincture of iron with plenty of water. The supervention of cardiac failure may be averted by the liberal use of whisky.

# A STATISTICAL RECORD OF FIVE THOUSAND CASES OF SMALL-POX.\*

BY WILLIAM M. WELCH, M. D.,

PHYSICIAN IN CHARGE OF THE MUNICIPAL HOSPITAL FOR INFECTIOUS DISEASES,
PHILADELPHIA.

RECOGNIZING the difficulty of interesting an audience by the narration of statistics simply, I have concluded to present the facts which I have to offer somewhat after the style of an object lesson. I shall mention but few facts that can not be seen clearly illustrated in the tables hanging before you.

Before calling your attention to these tables I should say that the opportunity to study and classify these five thousand cases of small-pox was afforded me in the Municipal Hospital for Infectious Diseases of Philadelphia during the period from 1870 until the early part of the present year. This period includes several epidemics of the disease, some of which were of considerable magnitude and great virulence, notably the epidemic of 1871-'72, which was almost world-wide and everywhere marked by unusual malignancy. During such visitations of the disease a very large proportion of the more severe and malignant cases were found among the admissions to the hospital. This is owing to two facts: first, since removal of patients to the hospital was not compulsory, most of the milder cases were treated at their homes; and, secondly, that a very large proportion of the patients were received from the lower class of society with constitutions exhausted or depraved by intemperance and other depressing habits. Even many of these were not received until all hope of re-

covery had passed. During the epidemic of 1871-'72 as many as a hundred and twenty-eight patients died in less than forty-eight hours after admission, while, indeed, a few others died in the ambulance on their way to the hospital, and all such are, of course, included in the statistics to be submitted.

I mention these facts in explanation of the unusually high death-rates to be seen in the tables. But while the death-rates are unusually high there is no disproportion in this respect between the vaccinated and the unvaccinated cases. That is to say—if the death-rate is excessively high in the one, it is to an equal degree excessively high in the other. There will therefore be no difficulty in measuring by these statistics the value of vaccination as a protective or modifying agent in small-pox.

This first table to which I shall call attention is one showing the cases classified accordingly as the disease was unmodified or modified. The former type, of course, is designated variola, and the latter varioloid, while the term small-pox, whenever used, must be understood as including both.

Table I.—Showing the Cases divided into Variola and Varioloid.

Disease.	Admitted,	Died.	Per cent. of deaths.
Variola	2,831	1,534	54.18
Varioloid	2,169	28	1.29
Total	5,000	1,562	31.24

All unvaccinated cases, all malignant cases, and all vaccinated cases in which the eruption advanced to the pustular stage and was attended by well-marked secondary or suppurative fever have been classified in this table as variola, while all the vaccinated cases in which the eruption was markedly abridged in its course and in which there was little or no secondary rise of temperature have been classified as varioloid. Under such a classification, a fatal result never occurs from the latter, except in greatly enfeebled constitutions or when some complication arises. While the death-rate was 54:18 per cent. from variola, it was only 1:29 per cent. from varioloid.

Table II.—Showing the Cases classified according to the Sex of the Patients.

Sex.	Admitted.	Died.	Per cent. of deaths.
Male	3,261 1,739	1,031 531	31.61 30.54
Total	5,000	1,562	31.24

The table shows that a considerably larger number of males than females was admitted to the hospital; and also that there is practically no difference between the death-rates of the two sexes.

Although the preponderance of cases is on the side of males, yet it can not be said that sex exerts any influence whatsoever over susceptibility to small-pox, nor that the disease, all things being equal, is more fatal among one than the

<sup>\*</sup> Read before the First Pan-American Medical Congress, September, 1893.

other. It is true that men are more frequently addicted to intemperance, and that this habit predisposes to malignancy of the disease; but, on the other hand, pregnancy in women is very liable to be followed by abortion, and when this accident occurs it always proves to be a very serious complication.

Table III.—Showing all the Cases classified according to the Color of the Patients.

Color.	Admitted.	Died.	Per cent. of deaths.
WhiteBlack	4,200 800	1,221 341	29:07 42:62
Total,	5,000	1,562	31 · 24

It is generally believed that small-pox is more fatal among colored persons than among whites, and the above table seems really to support such a belief; but before a reliable conclusion can be arrived at it is necessary that the patients of both colors should be observed under precisely the same circumstances—that is to say, comparison should be made between the unvaccinated of each color. Such a comparison may be seen in the following table:

Table IV.—Showing the Unvaccinated Cases of Small-pox, classified according to the Color of the Patients.

Unvaccinated.	Admitted.	Died.	Per cent. of deaths.
WhiteBlack	1,173 439	681 257	58.05 58.54
Total	1,612	938	58.18

Reference to the last two tables shows that of the two classes of patients—white and black—a very much larger proportion of the blacks were unvaccinated; of course, that accounts for the greater percentage of deaths among this class in the former table. In the latter table, however, where a comparison can be made between the unvaccinated of each color, it is seen that there is practically no difference in the death-rates, the deaths among the whites being at the rate of 58.05 per cent. and among the blacks 58.54 per cent.

I would not presume to say that all authors who contend that small-pox is more fatal among negroes than whites are mistaken in regard to their observations, but I wish to emphasize what I have already said—that no conclusion on this point is reliable unless both of these classes of patients have been observed under precisely the same circumstances.

Table V.—Showing the Cases classified according to the Vaccine Condition of the Patients.

	Admitted.	Died.	Per cent of deaths
Vaccinated in infancy, good cicatrices.		124 98	8.78
" " poor cicatrices.		290	27.10
Post-vaccinal cases	. 3,148	512	16.26
Unvaccinated cases	1,759	1,027	58.38
Unclassified cases		23	24 · 73
Total	.   5.000	1,562	31.24

In this table a comparison may be made between the vaccinated and the unvaccinated cases. For reasons already stated, the proportion of deaths in both is excessively high. Among the unvaccinated the death-rate is as high as 58°38 per cent., and among the vaccinated, as a whole, 16°26 per cent. Although high in both cases, the difference between the death-rates is very striking. If the 1,759 unvaccinated persons had been vaccinated in infancy, like the others, instead of 1,027 deaths among this class, there would have been only 286, a saving of 738 lives. Vaccination would have accomplished even more than this for these patients: it would have so modified the disease in a large proportion of those that recovered as to prevent much suffering and save them from disfigurement for life.

In examining the vaccine cicatrices of a large number of persons it is found that these scars differ considerably in appearance, and the question naturally arises, Can protection be measured to any degree by the different characteristics which they present? There is no doubt that many persons with quite inferior vaccine marks are fairly well protected, or even enjoy immunity from small-pox, while many with typical marks prove to be susceptible to the disease, and indeed often perish from it. But such results must, I feel sure, be regarded as exceptions to the rule. When a large number of patients are examined and the results tabulated, as the above table shows, the degree of protection, as indicated by the death-rates, is found to bear a very close and direct relation to the character of the vaccine cicatrices.

All of the patients represented in the tables were carefully examined on their admission to the hospital, and the number and character of their vaccine scars at once recorded. At this time it was, of course, generally impossible to foretell the final result. The scars were divided, according to their quality, into three grades, which are designated in the tables by the terms good, fair, and poor. Under the first head I have classified all cases presenting typical vaccine cicatrices-that is to say, cicatrices which are distinctly excavated, with well-defined margins, reticulated or foveolated, and altogether presenting the appearance of having been stamped into the skin by a sharply cut die. Under the second head I have classified all cases with scars having the same general characteristics, though much less distinctly marked. Under the third head have been classified all cases having scars which were said to have been the result of vaccination, but which in very many instances were so indistinct or uncharacteristic as to make it difficult, and sometimes even impossible, to recognize them as vaccine scars.

The cases classified under the heads of both good and fair marks had all, doubtless, passed through a well-marked, or reasonably well-marked, course of vaccina in infancy. The death-rates are respectively 8.78 and 14.71 per cent. But I am strongly of the opinion that very many of the cases classified under the head of "poor cicatrices" were never successfully vaccinated. Very often I felt fully convinced at the time of making the examination and recording the vaccine condition that such was the case, but, as the patients insisted that they had been vaccinated, I

could not reject their testimony without being considered, especially by the enemies of vaccination, a partial judge. It certainly does not detract from the reputation of vaccination to know that when the vaccine process is irregular, imperfect, or spurious the protection is diminished or absent. As the mean death-rate of the cases showing good and fair cicatrices is 10.68 per cent., and the death-rate of those showing poor scars is 27.10 per cent., it is evident that not only very many of the latter had been imperfectly vaccinated, but that a large number had never been subjected at all to the vaccine process.

It is impossible to illustrate in this table the very striking and conclusive evidence of the protective power of vaccination that frequently came under my notice while observing these five thousand cases of small-pox-such, for instance, as witnessing, on the one hand, an unvaccinated person suffering from the confluent form of the disease, loathsome and offensive, with the final issue for several days uncertain, and on the other hand a vaccinated person undergoing a modified form of the disease, so mild and innocent in its character as not to excite any apprehension for the safety of the patient. In the former case, if recovery took place, the individual was left disfigured for life, while in the latter, after a few months had passed, there was but little, if anything, in the appearance of the individual to indicate that he had ever suffered from the disease at all.

Also, I have seen over and over again entire families brought into the hospital when all the unvaccinated children have been suffering from small-pox and the vaccinated children unaffected; have seen the former perish and the latter remain exempt from the disease, although living, eating, and sleeping in the infected atmosphere for several weeks. But I have yet to see a single unvaccinated child escape the disease under similar circumstances. Furthermore, I have more than once seen a vaccinated infant draw its daily supply of nourishment from a mother suffering from varioloid, and the infant remain as free from any symptom of the disease as if the infection were a thousand miles away and the food were received from a most wholesome source. All this is evidence of the prophylactic power of vaccination that can not be shown in mortality tables.

Under the head of "unclassified cases" in the last table are included quite a large number of patients who were vaccinated after exposure to the variolous infection, and also a few patients who died and were buried before an examination as to their vaccine condition could be made.

The next table to which I shall direct attention is one illustrating the comparative efficacy of vaccination as performed in various countries, especially in the United States, Germany, and Ireland.

Perhaps I should explain, in the first place, that the high rate of mortality exhibited under the head of "unknown" nativity is owing to the fact that many of the patients therein represented were foreigners apparently, and were received into the hospital in a moribund state, so that it was impossible to learn their nationality. I may add also that under the head of "other nativity" are included

the patients who were natives of the various countries of the globe not designated in the table, excepting China and Japan, which countries furnished no patients.

Table VI.—Showing the Cases classified as to Nationality of the Patients and their Vaccine Condition.

	Admitted.	Died.	Per cent of deaths
United States:			
Not vaccinated	1,457	831	57.03
Vaccinated in infancy, good mark	686	53	7.72

Unknown:			
Not vaccinated	11	9	81.81
Vaccinated in infancy, good mark	5	2	40.00
" " fair mark	2	1	50.00
" " poor mark	1	1	100.00
Post-vaccinal cases	8	4	50.00

Referring to the table, it is seen that under the three nationalities therein given the death-rates of the unvaccinated cases of the United States and Germany do not differ materially, but the death-rate of the unvaccinated cases of Ireland is very much the highest. A comparison of the post-vaccinal cases also shows that the vaccinated patients of Irish birth have perished in the largest proportion. This seems to indicate that small-pox is most fatal among the Irish—a fact which, I believe, I have noticed in every epidemic of the disease that I have witnessed.

The difference between the rates of mortality among the cases showing "good" marks, as is seen under the three nationalities mentioned, is not great, and the slight difference that does exist may be entirely accidental. But the difference between the death-rates of those showing "poor" marks is very great and decidedly in favor of the patients of German birth. The vaccinations performed in Germany prove to be more uniformly protective, and hence the death-rate among the post-vaccinal cases under this head is the lowest of any of the nationalities. All this seems to prove that vaccination is most efficaciously performed in Germany. The comparative exemption of Germany and the German army from small pox is simply a striking example of the brilliant result of careful and efficient vaccination.

When most of the vaccinations represented in the table were performed it was customary in the United States, and in Ireland also, I believe, to use humanized crusts; but in Germany fresh eighth-day lymph or arm-to-arm vaccination was the means or method employed, and this method has always given the very best results. Hence I think it is not improbable that the German patients owe their better protection to the superior quality of the vaccine lymph generally employed in their country.

There is another explanation that might be offered to account for the superior protection enjoyed by the German patients-namely, that it is the practice in Germany in performing vaccination to make numerous insertions of the vaccine virus. In examining the arms of patients of German birth it is quite common to find three distinct scars on each arm, and even a greater number is frequently met with. I have seen as many as twenty typical vaccine marks on the arms of a German patient. If multiple insertions of the vaccine lymph increase the protection against small-poxand statistics are not wanting to show that such is the case -surely German subjects should be well protected. But, in view of the facts which will appear in the following table, I am inclined to believe that the Germans owe their superior protection from small-pox more to the quality of the vaccine virus they use than to the number of insertions they make.

Table VII.—Showing the Cases classified as to the Number and Character of the Vaccine Scars borne by each Patient.

	Admitted.	Died.	Per cent.

Total number showing four or more marks	424	45	10.61

<sup>\*</sup>The cases classified in this table as claiming to have been vaccinated, but showing no visible mark, are included in the other tables among the unvaccinated. So, also, quite a number of those classified

The first thing to be seen in this table is that there is practically no difference between the death-rates of the unvaccinated patients and those professing to have been vaccinated but showing no visible mark. This proves that there was either a mistake as to the alleged fact or that a vaccination which is followed by no mark is devoid of protective power, most probably the former.

The table also shows that vaccination practiced after exposure to the infection of small-pox may afford considerable protection against the disease. If it be performed within two or three days after the infection has been received into the system it is possible for the protectio ton be absolute. I have seen as many as twenty-eight children perfectly protected from small-pox by vaccination during the incubation period.\* But if the vaccination be performed much less than seven days before the eruption of small-pox appears, no modifying influence will be exerted. In a considerable number of the cases included in the table under the head of "vaccinated seven days and less prior to the appearance of the variolous eruption" the patients had been vaccinated no longer than from two to four days before the eruption appeared, while a somewhat larger number had been vaccinated as long as from four to seven days before it appeared. Taking the whole number of cases under this head, it is seen that the death-rate is 43.86 per cent., while among the unvaccinated it is as high as 58:18 per cent. This shows that considerable protective influence must have been exerted by vaccination performed during that period. But a still greater influence was exerted among the cases included under the succeeding head, where vaccination is represented as having been performed longer than seven days before the small-pox eruption appeared. The death-rate here is only 20.27 per cent.

In regard to the matter of estimating the efficacy of vaccination by the number of vaccine cicatrices borne by each person, the table can not be said to support the views of most authors, nor does it accord with the experience of some other observers. It is, indeed, in striking contrast with the evidence on this point collected by Mr. Marson and tabulated by Mr. Simon. According to these authors, who derived their data from six thousand post-vaccinal cases of small-pox, the mortality-rate among patients having one vaccine scar was 7.5 per cent.; having two, 4.125 per cent.\*; having three, 1.75 per cent.; having four or more, 0.75 per cent. Where the vaccine scars were all well marked or typical, the loss by death is said to have been even less than is here indicated.

The table shows, it is true, that the highest death-rate is among the patients having but one vaccine mark, but unquestionably this is owing to the fact that a very much larger proportion of the patients under this head than under any other showed "poor" marks, and, as already pointed out, very many of these patients would be more

in this table as having been vaccinated during the incubation period of small-pox are included among the vaccinated or unvaccinated in some other tables, which fact will explain some discrepancies in numbers.

<sup>\*</sup> For further information on this subject see my paper on Vaccination during the Incubation Period of Variola, published in the *Transac*tions of the Ninth International Medical Congress, vol. iv, p. 160.

correctly classified if counted among the unvaccinated cases. Those having four or more "poor" marks are in a much smaller ratio to the total number of post-vaccinal cases under that head than under any other, and the death-rate, to be sure, is remarkably low. It is, indeed, almost as low as among those showing four or more "good" marks. The explanation of the low death-rate here is that nearly all the patients classified under this head were natives of Germany, where, as already shown, vaccination is so efficiently performed that if the scars are not in every respect typical there is, nevertheless, well-marked protection.

Referring again to the table, it is seen that, where the vaccine scars are typical, there is no relation between the number of such scars and the degree of protection conferred against small-pox." Indeed, it so happens in the table that the death-rate among the patients having but one "good" mark is a little lower than among those having four or more "good" marks. There is no doubt that vaccina characterized by a single typical vesicle destroys in the individual all susceptibility to small-pox, and it would be impossible for multiple vesicles to do more than that. As a safeguard against failure, however, or when using long-humanized virus, it is advisable to make several insertions; but I must repeat that it is my positive conviction that quality of vaccine lymph has far more to do with securing efficient vaccination than multiple insertions have.

(To be concluded.)

# THE ALBUMINURIA OF ADOLESCENCE.\*

BY PAUL E. TIEMANN, M. D.

DURING the last few years I have been surprised at the frequency with which albuminuria has appeared in young men and boys.

Ont of a total of nearly two thousand examinations that I have made in the last few years, the great majority of which were of adult males, the percentage of albuminuria was a little over nine in a hundred. Out of this total, a hundred and eighty-six were below twenty-one years of age (few, if any, being females), and in these the total albuminurias were fifty-one, or 27.4 per cent.

· As I knew very little about the subject of this paper, I determined to investigate it, and the results are laid before you to-night. I hope that their recital will not be wearisome to you. I can assure you beforehand that I have never found the topic a "dry" one.

Ætiology and Occurrence.—Intermittent albuminuria occurs in the majority of cases among young persons. Thus Dubreuilh (1), in thirty-four males with this symptom, found the average age to be twenty-three, fourteen being between sixteen and twenty. In five females it was fourteen, all being below twenty.

Saundby (2), out of forty-two cases in out-patients with various ailments, classed sixteen among the albuminurias of youth.

Finot (3) made repeated examinations of the urine of

seventeen pupils of a military school for thirty-five consecutive days, under various conditions and at different hours, and found albumin at some time or other in all but three.

Other observations in which the percentages of albuminuria were high have been made on soldiers (who are apt to be young recruits, at least in Continental armies). Thus Capitan (4) found it in 44.9 per cent.; Van Noorden (5), three to thirty-five per cent.; and Chateauborg (6) in two hundred and one out of two hundred and thirty cases. Dukes was struck with the frequency with which he encountered periodical albuminuria among the boys at Rugby. Stewart found albumin among children in from four to sixty per cent. Goodhart (7) states that, out of thirty-nine cases of albuminuria without known cause, twenty-seven were below thirty years of age. In thirty-two the albumin disappeared in forty-eight hours.

Tyson (8) says that albuminuria occurs in children between the ages of nine and eighteen without apparent reason; its origin is renal, but casts and other evidences of Bright's disease are absent. It is much more frequent in boys than in girls; is increased by the ingestion of food and by fatigue; is almost always absent in the early morning, returning with the renewal of muscular exercise without reference to food. While it is impossible to definitely account for its causation, he thinks it may be due to a defect in the composition of the albumin of the blood caused by malassimilation, in consequence of which it escapes through the walls of the blood-vessels. Still, no chemical difference between the albumin in cases of the functional variety and that of those with renal disease has as yet been discovered.

Kinnicutt (9) attributes the albuminuria to the irritation of the kidneys by oxalates, urates, uric acid, etc., and the resultant vaso-motor disturbance, whence a transient dilatation of the renal arteries, retarded blood current in the glomerular vessels, and temporary alteration in the function of the glomerular epithelium.

Gaston (10) and Lecorché (11) believe that in the majority of cases there must be a pathological change of a fleeting character, too trivial perhaps to be noticed, such as a slight localized glomerulo-nephritis.

Fürbringer (12) thinks it may be due to a dilatation of the vessel wall and a diminution in the rapidity of the blood current, this change being partly dependent upon local and independent vaso motor centers.

Herringham (13) considers it as generally the sequel to some acute disease, especially the exanthemata, or to rheumatism or malarial disease.

Da Costa (14) says the kidneys become congested from the irritation of uric acid, oxalates, and urates, and there may be slight inflammatory changes in the vascular cortex.

Dukes (15) claims it is caused by arterial hyperæmia, as evidenced by the hard pulse he frequently found, and which he regarded as a valuable diagnostic symptom. The sudden change from the recumbent to the upright position is responsible for the albuminuria soon after rising, and he believes that if the person could be very gradually moved from a horizontal to a vertical plane, thereby giving the circulation a chance to accommodate itself, this would not

<sup>\*</sup> Read before the Hospital Graduates' Club, January 25, 1894.

occur so soon; conversely, if human beings roosted like chickens, the albuminuria would be constant, not intermittent.

Beneke (16) attributes it to the relative hypertrophy of the heart at puberty, the vessels remaining comparatively narrow, an increased arterial tension with hyperamia resulting.

Wood (17) ascribes the same cause in some; in others, the irritation of non-oxidized substances in the tubules. The urine of children, he says, is very apt to be concentrated, because they do not drink enough fluid. He mentions several cases of slight albuminuria, with casts and blood, in which the specific gravity was between 1.028 and 1.034; but all symptoms disappeared as soon as the urine was diluted.

Lucas (18) maintains that albuminuria of adolescence is only one of the manifestations of rhachitis, as evidenced by spinal curvatures, enlarged epiphyses, flat feet, and knock-knees, often seen developing at this period.

Heredity.—Dubreuilh (1) cites two cases of intermittent albuminuria with oxaluria in which the patients finally recovered. One was a young man of nineteen years in whose brother Sir William Gull had discovered the same condition several years before, though at that time the latter's urine was normal. The other was a rather delicate youth of nineteen, whose younger brother also had albuminuria.

Lecorché (11) and Talamon instance two sisters whose father died of Bright's disease, whose paternal and maternal grandmothers were both albuminuriaes, and whose paternal grandfather died of diabetes. The girls had albuminuria for a long time without any apparent effect upon their health.

Teissier (19) states that these cases of periodical albuminuria are the children of arthritic parents, and are themselves destined to become gouty or rheumatic.

Reflex Disturbances; Extremes of Temperature.—Auld (20) quotes the records of the London Fever Hospital to show that scarlatinal nephritis is most frequent during hot and relaxing weather, and also affirms that apparently healthy persons may have slight albuminuria from the same cause. He describes the experiments of Senator, who discovered albumin and casts in the urine of animals whose temperature had been raised 1.5° to 3° C.\*

Harley (21) makes reference to Cheen's Diseases of India, in which the latter speaks of the frequency of albuminuria, apart from organic mischief, in anæmic Europeans. While so often observed in whites, Harley found albumin extremely seldom in the urine of natives (absent in every one of two hundred healthy young recruits); on the other hand, glycosuria was readily demonstrated in almost all of these men.

The doctor's statement that only five per cent, of them ever touched meat, the rest living upon rice and other vegetables, might explain this phenomenon. A medical mis-

sionary who had spent many years in India told me that his experience had been similar to Harley's.

Barnes (22), while physician to the Seaman's Hospital, often treated eases of immersion during cold weather that were followed by a transient albuminuria.

Ellis (23) describes experiments upon healthy young rabbits and dogs in which they were shaved, subjected to a high temperature, and then suddenly plunged into ice water, in which they were kept for one to three minutes. There was a decided fall in temperature, the animals trembling for some hours afterward, though placed in a warm atmosphere. In one or two days albuminuria developed with a few hyaline casts, disappearing after a time. In a few it persisted, and the animals died. Examination showed interstitial inflammation of the internal organs, especially the liver and kidneys.

Bouchard (24) speaks of reflex albuminuria provoked by excitation of the cutaneous nerves. Thus at the Hospital St. Louis, where frictions with turpentine were frequently employed, it was noticed that urines which were entirely normal before the friction were frequently albuminous afterward, and this albuminuria appeared too quickly for the turpentine to have been absorbed.

Food and digestion do not, I think, have any marked influence in the causation of albuminuria; certainly in chronic cases it is most marked in the forenoon and middle of the day before much has been eaten, and is least in the afternoon and evening when digestion is at its height. Again it has been found that when the subjects stayed in bed albuminuria did not appear, though the meals were eaten regularly, but that it immediately developed when they got up, even though they fasted. (See Pavy, London Lancet, 1886, i.) Admixture of prostatic and seminal fluid with the urine was said by Goodhart (7) to account for the albuminuria in eight of his thirty-nine cases.

Simon (2), on the contrary, declares that these fluids do not contain any albuminous body coagulable by heat. Out of one hundred cases that I examined microscopically I found spermatozoa only once in any quantity, and here two successive analyses failed to discover albumin.

In another case spermatozoa were found only a few times out of many careful examinations, and yet there was a well-marked periodical albuminuria extending over a period of one year.

Return to the Embryonic Type.—Finally, Ribbert (13), who found that embryonic kidneys almost invariably secreted albuminous urine (as do the kidneys of the newly born), advances the theory that slight causes may induce the adolescent kidney to temporarily assume this embryonic quality.

If we may credit the statement of some authorities, such as Ballet (25) and Dreyfuss-Brissac (26), that albuminuria is extremely uncommon in cases of senile kidney (and by this they mean a small, red, contracted kidney), this assumption of Ribbert's is not an extravagant one, for in the one instance we have a youthful organ which is the seat of unusual growth and activity, while in the other there is a condition of atrophy and decay.

Diagnosis.—Pavy (27) claims that the following points

<sup>\*</sup> In a number of analyses that I made last August and September I was impressed with the frequency that albuminuria showed itself when there was a combination of high temperature and a high degree of humidity.

enable him to differentiate between physiological and pathological albuminurias:

a. Absence of albumin in the early morning, its presence in the forenoon, reaching a maximum toward midday, then decreasing toward evening, and often disappearing entirely at bed times.

This series of phenomena is repeated day after day and likened by him to the periodical appearance and disappearance of phosphates.

b. No impairment of the health and no constitutional evidences of nephritis, such as cardiac hypertrophy or arterial tension, dropsy, retinitis, etc.

c. Absence of tube casts, presence of oxalate of lime, and a urine of high specific gravity.

While many authorities agree with Pavy (see Davis (28), Bouchard (24), Dubreuilh, Sir Andrew Clark (29), and others mentioned by Vanderpoel (6)) that an albuminuria of such a description is not due to nephritis, whatever may be its ultimate tendency, there are others who take an opposite view.

Thus Goodhart (in Keating's Cyclopædia of the Diseases of Children, 1890, vol. iii) says that "any albumin that is present again and again in the urine of any child or adult is as conformable to the hypothesis of the existence of a nephritis \* as it is to that of functional disease."

Lecorché and Talamon (11) incline to this belief, as does also Collier (30), who, when interne at the Wolverhampton Hospital, treated a large number of patients with nephritis, and found that the early morning urine often contained only the smallest traces of albumin, the amount of which was also at other times in the day greatly decreased by rest in bed.

Bartels (31) relates the case of a vigorous young man who had albuminuria upon admission to the hospital, but none early the next morning. He remained a patient for four months, and as long as he kept his bed albumin was never found. Indeed, its sudden appearance betrayed the fact that he had disobeyed orders and got up. Although frequent and thorough search was made, casts were never detected. Nevertheless, a diagnosis of contracted kidney was made, based upon the low specific gravity of the urine, a tense and rigid radial pulse, and hypertrophy of the left ventricle. Casts, if present in quantity or constantly, are indications of Bright's disease, although conversely they may be scanty or even absent in fatal cases of nephritis. Thus Washburne (32) describes two cases of persistent albuminuria that died within four years after the first examination, in which tube casts or cellular elements could never be found.

Radomyski (33), using the centrifugal apparatus, found casts without albumin in urines of specific gravity ranging from high to low; still he did not consider them as the product of entirely normal kidneys.

Danforth (34) says that if only occasional hyaline casts are discovered, the exudation is probably very slight; if the cast is smooth in outline and free from "twists," it would seem to indicate that the tubule had not been invaded by pathological connective tissue.

Other authorities quoted by Vanderpoel do not consider casts, under certain circumstances, to be necessarily a symptom of renal disease.

Cardiac hypertrophy, rapid pulse, and arterial tension would indicate nephritis.

Kinnicutt (9) made sphygmographic tracings in all his cases and found the tension always either normal or subnormal. Vanderpoel describes the pulse of functional albuminuria as a soft one. Dukes, on the contrary, found it apt to be hard and rigid. In my experience it has been

The symptoms and course will be best described by the relation of a few cases.

(a) Merklen (35) gives an account of a boy of sixteen years, rapidly growing, and of arthritic parents. Well-marked albuminuria from noon till midnight; none from that time until early in the forenoon; albumin never present in the first urine passed in the morning on rising. No cylinders; only a few red blood-cells. Milk diet had no effect on the albuminuria.

The boy's eyes were carefully examined by a competent oculist and found to be normal, except that the retinal veins were moderately congested, this condition being considered by Merklen to be analogous to the passive congestion which he observed in the boy's extremities and indicative of vaso-motor atony. In an attack of pulmonary congestion, with high temperature, during which he was kept in bed for three weeks, albumin was never found, though the urine was examined daily at different hours. It promptly reappeared as soon as he was allowed to get up, though from that time it was less marked and the general health was better.

(b) R. H. Meade (36) relates the case of a young man whose early morning urine was never albuminous, while that of the forencon and night was decidedly so. The microscope showed a few hyaline casts and some oxalates. He was delicate and nervous, but had no indications of organic disease. He was confined to the bed two months by an accident, and all this time the urine was absolutely free from albumin, which showed itself at once when he began to go about again. Here treatment affected nothing.

(c) T. M. Rooke (37) had under observation several growing girls between fourteen and sixteen years who had no symptoms of renal disease other than slight anæmia and albuminuria. The latter was regularly absent upon rising, though uniformly present later in the day. It never appeared when the girls were kept in bed.

(d) Herringham (13) tells of a boy of thirteen years, rather thin and pale, with a feeble, soft pulse. While in bed albuminuria was present only three times out of thirty-four, but when he was up it was found tweuty-nine times in fifty analyses. The amount or kind of food did not seem to influence the albuminuria—in fact, this was most marked at noon, just before dinner. It then diminished, and later in the evening was either absent or reduced to a mere trace. No casts were ever found, but oxalate-of-calcium crystals were not infrequent.

(e) William Collins (38) gives details of three periodical albuminuriacs, aged eighteen, twenty-two, and twenty-five years. All had nervous depression, languor, indigestion, constipation, and headache.

The specific gravity ranged between 1.020 and 1.030; there was well-marked oxaluria, which seemed to be in direct ratio to the quantity of albumin. These all finally recovered.

<sup>\*</sup> In the case of young persons I understand this to mean the parenchymatous variety, the contracted kidney being quite infrequent in early life.

(f) Mareau (39) devotes an article to a child of ten years, apparently in the best of health, who had never had scarlatina or any other serious illness. His father, an expert chemist and biologist, accidentally discovered the albuminuria, and afterward made a large number of tests of the urine. Out of four hundred and forty-seven examinations made while the child was in a normal state of health albumin was absent in 46.75 per cent.; present in small traces (three milligrammes to the litre) in 43.18 per cent.; and in well-marked traces (two to sixty centigrammes to the litre) in 10 per cent. In the urine passed upon rising, albumin was absent forty-five times, present (generally only in small traces) sixty-eight times; but this preponderance of albuminous urine was partly explained by the fact that the child went to bed soon after supper and did not, as a rule, urinate until it arose. Whenever the bladder was emptied during the night, the morning's urine was regularly normal.

During an attack of rötheln seventy-four examinations were made; in the period of invasion and convalescence well-marked albuminuria was observed almost exclusively after breakfast and dinner, while throughout the period of eruption, when the child would not eat, it was only the urine passed upon rising that contained any quantity of albumin.

On the assumption that about forty-five cubic centimetres of normal urine are sufficient to destroy one kilogramme of living matter, whereas from a hundred and twenty-five to a hundred and fifty cubic centimetres of nephritic urine are necessary to produce the same result, Mareau made use of injections of the urine taken from albuminous samples passed during the day, and found that only about eighty cubic centimetres killed a rabbit weighing 1,765 grammes.

Lecorché and Talamon (11) relate the further history of this child. His father wrote them six years later that he was in excellent health, of fine muscular development, and had steadily continued his studies. As a general thing, albumin was absent or present only in traces, though it was apt to become more abundant and continuous during the course of the minor ailments to which children are prone. Treatment had availed very little; sea baths had no other effect than to temporarily change the hour at which the albumin was most abundant; tonics decreased the quantity of albumin and made it disappear for a time. A milk diet made the child thin and weak if kept up even for a few weeks. Casts had never been found. An examination of the thorax showed that the cardiac impulse was forcible and the sounds exaggerated, a symptom which the -authors regard with suspicion, though it might have been only the overaction frequently present at puberty.

E. S. Wood (17) made repeated analyses of the urine of a boy (aged thirteen years when first seen) from February, 1885, till February, 1891. The first examination showed a trace of albumin, a few red blood-cells, renal cells, and an occasional hyaline cast. Through the spring, summer, and autumn of the same year albumin was present with hyaline casts, oxalate of calcium, and uric acid; the specific gravity was rather high.

In August and October, 1886, albumin and casts were absent, but there was an oxaluria and a specific gravity between 1.024 and 1.030. In July, 1887, and January, 1888, the urine was normal; in July, 1890, a trace of albumin, but none the following month, and none in 1891.

(g) Washburne (32) had under his care a robust young man of seventeen years whose occupation was an outdoor one. His urine was albuminous on a number of different occasions, but never at 1 A. M. The albuminuria was greatest after a long

horseback ride on a cold November day; in fact, it was more marked in winter than in summer. One year later several analyses showed the urine to be entirely normal.

- (h) Ralfe (40) points out the occasional connection between albuminuria and hæmoglobinuria, the latter being essentially a disease of young adult males. He maintains that albuminuria associated with hæmoglobinuria often shows the same daily variation as the functional and uncomplicated variety, and describes three cases of persistent albuminuria in which the subjects passed bloody urine after being chilled.
- (i) The following are examples of malarial albuminuria (Dubreuilh): In the first the urine was markedly albuminous in the forenoon and at 11 P. M.; normal at noon. In the other there was a clear history of intermittent fever some time before; daily albuminuria greatest at 9 A. M. and 9 P. M.; absent at 3 P. M. The albuminous urine was distinctly acid; specific gravity, 1.020 or thereabouts; the non-albuminous was 1.008, pale, and only slightly acid. Diuretics produced a cure.
- (j) I have had under observation since November, 1892, a boy of sixteen who appears in good health except that he has had a typical periodical albuminuria. He has never had any serious illness; no history of scarlatina. His complexion is somewhat sallow, but the number of red blood-cells is normal and, though rather undersized for his age, he is muscular and well built. The heart and pulse are entirely normal, and the fundus of the eye, examined this month by Dr. J. E. Weeks, does not show the slightest evidence of renal disease.

As a rule, the early morning urine has been free from albumin (seventy-eight out of eighty-four examinations), while the noon urine has been as regularly more or less markedly albuminous (ninety-eight in a hundred and thirteen). Thirty-three analyses of the forenoon urine (8.30 a. m. to 12 m.) were made: eighteen were albuminous, fifteen non-albuminous. Out of ninety-three specimens examined that were passed at bedtime, forty-two contained albumin and fifty-one did not.

In a bundred and forty-five microscopical examinations, in most of which the sediment was obtained by the centrifugal apparatus, which was often further controlled by examination of a specimen that had stood twelve to eighteen hours, I found undoubted casts (hyaline and epithelial) only four or five times, and then they were very scanty. Oxalate of calcium and mucus were often present, uric acid occasionally; sometimes a few red or white blood-cells.

There seemed to be a proportionate ratio at times between the quantity of oxalates and lithates and that of the albumin, but this was by no means constant, for often when the latter was present in larger amount there was absolutely no sediment beyond a few superficial epithelial cells.

The specific gravity ranged between 1.020 and 1.030, rarely below the former figure. In November and December last it was often very high and oxalates and lithates were abundant. I learned that he drank very little fluid, so I put him on dilute nitrohydrochloric acid before meals with a glassful of hot water three or four times a day. This treatment has greatly diminished the quantity of albumin, so that now it is either absent at hoon (the time when it was formerly most marked) or present only in traces. The specific gravity is much lower and the oxalates and lithates are not nearly so abundant.

(k) During the past six months I examined the urines of a number of boys between ten and twenty years old; almost all led an active out-of-door existence, and, with comparatively few exceptions, were fully up to the average in health and physique, if not above it.

The first series of examinations was made in August, September, and October, between 7 and 8.30 p. m., and

comprised a hundred and four different boys selected at random, each being examined but once. Their general condition was noted and the state of the thoracic organs carefully investigated, but very little could be learned of their past history, as no boy that had a home was received at the institution where they were, and their personal recollections were very slight. The urine was tested for albumin (usually by the heat test),\* in the majority of cases for sugar, and the specific gravity was taken. All but four were examined microscopically; in nearly all the centrifugal machine was used, often supplemented by a specimen set aside for twenty-four hours, though this latter procedure gave no better results, often not so good as the apparatus.

The following is a summary of the results of these examinations:

Total number examined, 104; total number of albuminurias, 31; percentage of albuminurias, 29.8 per cent.

Total albuminurias with casts, 9; number in which casts were at all abundant, including hyaline, granular, and epithelial, 5; number in which they were hyaline and scanty, 4; number with pus enough to account for albuminuria (urethritis), 2; number of albuminurias in which the subject was in poor health or temporarily ill, 10. Of these, there were cardiac disease, 1; anæmia, rhachitis, 4; acute bronchitis, amygdalitis, 3; suspected phthisis, 2. Number of persons in poor health or temporarily ill (without albuminuria), 17; cardiac, 9; rhachitis (anæmia), 4; specific disease, 1; bronchitis, 2; lymphoma (abdominal glands), 1.

The cases of cardiac disease were notably free from albumin, as I have often noticed as long as compensation is kept up.

Microscopical examinations, 100; casts (two or more, in three or more slides) present in 22; with albumin, 9; without albumin, 13; well-marked oxaluria, 9; well-marked lithuria, 5; spermatozoa in noticeable quantity, 1.4

Another series of a hundred and thirty-six examinations was made this past fall and winter; eighty-eight urines were passed between 1 and 2 P.M., and forty-eight between 6 and 8 P.M. Of these, twenty-two were albuminous, or sixteen per cent. This lower percentage of albuminuria may have been partly due to the fact that in the later tests were included a number of boys who did not show any albumin in the earlier ones.

Of the albuminurias observed in the first series, twentyone were lost track of, six disappeared, and three persisted. Out of these last, two were associated with glycosuria and (microscopically) abundant casts. The third was a boy of fifteen, in whom no apparent cause was to be found for the presence of the albumin.

Sugar was found three times out of a hundred and ninety-one analyses—twice associated with albuminuria and abundant casts, once with cardiac disease.

Of the records of specific gravity, fifty-two were below 1:020, a hundred and five between 1:020 and 1:025, fifty-

three between 1.025 and 1.030, eight between 1.030 and 1.035, and two over 1.035.

In the albuminous urines (where taken) the specific gravity ranged as follows: Below 1.015, one; 1.015 to 1.020, eleven; 1.020 to 1.025, twenty-four; 1.025 to 1.030, nine; 1.030 to 1.035, one; 1.037, one—total, thirty-seven.

To recapitulate: Two hundred and forty analyses, fifty-three albuminurias (twenty-two per cent.); three glycosurias (1.25 per cent.).

Prognosis.—Authorities differ widely as to the significance of intermittent albuminurias, some contending that they are harmless, others that they are the precursors of chronic Bright's disease unless promptly treated. Vanderpoel relates two instances of what at first appeared to be the functional variety which finally developed nephritis, and in his paper a majority of the authors quoted regarded the continued presence of albumin as a pathological symptom.

Dubreuilh (18) says that albuminuria may continue for months or years; may stop for a while and again appear; it is never certain that it has entirely ceased. When present, it is a "black cloud" on the horizon.

Lecorché and Talamon (11) maintain that it is impossible to attach any diagnostic value to the presence of albuminuria in children; and Washburne (32) says that kidneys which have once shown themselves to be impaired, even if only for a short time, will be more liable to disease in later life than those which have been normal.

Treatment.—The form associated with high specific gravity, oxaluria, and lithuria seems to be the most amenable to treatment. As hepatic stimulants, dilute nitrohydrochloric acid and sodium phosphate are regarded as specifics, the latter being preferable when constipation is present. An occasional dose of calomel or blue mass is to be regarded in the same light.

Other valuable aids are the weak alkaline waters, plenty of ordinary water, either hot or cold, tonics, regulation of the, diet and rational hygiene.

In conclusion, I wish to express my thanks to Dr. F. A. Manning, Dr. J. E. Weeks, and Dr. Henry E. Crampton for assistance rendered and courtesies extended.

### INOPERABLE SARCOMA OF THE NOSE.

BY ROBERT LEVY, M. D.,

PROFESSOR OF PHYSIOLOGY AND LARYNGOLOGY, GROSS MEDICAL COLLEGE;
LARYNGOLOGIST TO
ARAPAHOE COUNTY, ST. LUKE'S, AND DEACONESS'S HOSPITALS, DENVER, COL.

ADDITING Plicque's \* classification of malignant tumors of the nasal cavities, the following case is placed in the fourth or inoperable class:

On September 21, 1893, J. L., male, aged sixty-two, by occupation a farmer, was referred to me for examination and advice by Dr. Wiest and Dr. Toplif, of Longmont, Col.

In the family history of the patient there was nothing of interest except that his mother died at the age of seventy of a "tumor" of the liver. He has always been healthy and strong; is the father of three children, one of whom died at the age of five weeks of "scrofula" and a "troublesome sore on the neck." He has been a sufferer from "catarrh" for twenty years, which he states has been gradually getting worse. Present illness dates back several years; the exact date of its origin is indefinite. Three years ago he first noticed that the discharge from his nose was becoming offensive. Several years ago he lost the sense of smell, which has not returned. In April, 1890, he began having intense pain in the forehead. In August of the same year the region of the left superior maxillary and malar bones became swollen. There was a burning sensation in the region of the cavity of the antrum. About the same time there developed partial facial paralysis of motion, involving the superficial muscles from the lower lid to the upper lip upon the left side. There was slight loss of sensation of the upper lip. Since August his strength has been rapidly

failing; his appetite has been nil; on account of the intense pain, he has been unable to obtain a night's rest. The character of the pain has been lancinating, becoming more and more intense of late, radiating from the autrum to the left side and root of the nose and forehead, being at times very intense in the occipital region.

Upon examination, we find a large, well-developed man, somewhat emaciated, with an expression of intense suffering upon his face. A decided swelling exists over the middle and malar portions of the left superior maxillary bone and over the malar bone. The skin covering this region is tense and of a dusky hue. The eye is watery. Examination of the nose reveals a small polyp springing from the under surface of the middle turbinate on the left side, and a considerable amount of thick, dark-green pus with an intensely fætid odor-the odor of necrotic tissue. The existence of the pain, the fætid odor. the purulent discharge, the swelling, and the presence of the nasal polyp, at once directed our attention to the probability of an existing, long-standing empyema of the antrum. The intensity of the symptoms and the odor pointed also to a syphilitic lesion or some form of malignant growth. The absence of any history of syphilis or of any previous symptom of that affection led us to believe that the case was probably one of either cancer or long standing antrum abscess. Transillumination of the cavity of the antrum revealed characteristic and definite results, and the advisability of opening the antrum was apparent. Upon gaining the patient's consent, the antrum was opened by Dr. Bartleson through the alveolar process, when there was at once a profuse discharge of green, intensely fætid pus. A goldplated tube was firmly fixed in the opening, antiseptic and stimulating solutions were given to the patient, and he was advised to return home and continue washing the antrum for a period of time. The polyp was removed with the cold snare. The result expected was either great improvement or, if the case proved one of malignant growth, it would rapidly progress. Some relief to the pain and some correction to the odor were obtained. Soon the symptoms returned with increased violence, and on the 20th of October he presented himself again. On the 19th of October he had his first nosebleed, which was quite profuse. At this time also there was noticed difficulty in swallowing, especially liquids. Upon examining him the swelling over the cheek was seen to be slightly increased. The examination of the nose revealed a small gravish. irregular mass beneath the middle turbinated bone in the neighborhood of the ostium maxillare. From the rapid increase in the symptoms some form of malignant growth was quite definitely settled upon as a most likely diagnosis. This outgrowth appearing in the nose gave additional proof to the diagnosis, and a small portion removed with a cutting forceps was examined microscopically by Dr. Axtel. It proved to be, according to the doctor's report, a large-celled sarcoma, in which were found many small round cells, embryonic bloodvessels, and a slight attempt at connective-tissue formation. On October 25th the patient discharged two large masses of necrosed tissue from the nose. There also appeared some difficulty in vision. An examination by Dr. Le Mond detected interference with the action of the internal rectus, causing diplopia. There was also considerable ædema of the ocular and palpebral conjunctiva of the lower lid. The pain continued to increase, becoming especially marked at the base of the brain. The difficulty of swallowing rapidly increased, the patient's strength soon failed, and he died of exhaustion November 24, 1893. Unfortunately, an autopsy could not be obtained.

At no time were any of the adjacent glands enlarged or affected.

<sup>\*</sup> A Study of the Diagnosis and Treatment of Malignant Tumors of the Nasal Fossæ. Journal of Laryngology and Rhinology, May, 1890.

Passing over the interest attached to the existence of such rare growths in such still rarer situations, the case reported presents several points worthy of attention:

- 1. The anatomical parts involved, as indicated by the subsequent train of symptoms. (a) Paralysis of motion, involving the periphery of branches of the facial distributed over the superior maxillary bone, showing local pressure. (b) Paralysis of sensation due to pressure in the course of the second division of the fifth. (c) Paralysis of deglutition due to pressure upon Meckel's ganglion, from which are derived the palatine nerves which supply muscles largely concerned in the act of swallowing. (d) The pain in the face and eye, accounted for by pressure upon branches of the fifth. (e) The pain in the eye and that in the occipital region, accounted for by pressure in the neighborhood of the sphenoid bone. Finally, there is every reason to believe that from these pressure symptoms the tumor must have existed not only in the nose and in the antrum, but must have extended into the spheno-maxillary fossa, as well as into the body of the sphenoid bone.
- 2. The presence of the nasal polyp. This brings us to the much-discussed question of the relation of polypi to the development of malignant tumors. It is plain that in this case the polyp was simply coexistent.
- 3. The necessity of determining the point of origin of the growth as well as its extent. This is particularly important in the matter of the treatment, for if it could have been definitely determined that the growth began in the nose and extended only into the antrum and the adjacent superior maxillary bone, an operation might have been undertaken. With the intensity of the symptoms referring us to extensive nerve pressure and the small amount of nasal disturbance, one might definitely conclude that the growth did not begin in the nose and that it extended into deep structures.
- 4. The intensely fatid discharge from the antrum. This discharge was characteristic of necrosed tissue, and, while in many cases of long-standing empyema of the antrum we have a fortid odor, still the difference between the odor from abscess of this cavity and the penetrating fortor found in malignant cases merits attention as a differential diagnostic feature.
- 5. The severe pain in the forehead. This occurred early in the case reported above, and in the majority of cases of malignant tumors of the nose this appears as an early symptom. In an admirable report of five cases of malignant tumor of the nose by Neuman \* this symptom is particularly noticeable.

The Presbyterian Hospital of Philadelphia.—The last will of Mrs. Martha Abbey gives to the institution the sum of \$55,000. A part of this is to be received at once, and a part is reversionary upon the death of certain individual beneficiaries.

The Buffalo Academy of Medicine.—At the last meeting of the Section in Medicine, on Tuesday evening, the 13th inst., the special order was a paper on Stimulation and Stimulants, by Dr. Eli H. Long.

Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MARCH 17, 1894.

· MEDICAL OBSERVATIONS AMONG THE ESKIMOS.

In the March number of the New York Journal of Gynæcology and Obstetrics there is an interesting article with this title, by Dr. Frederick A. Cook, the ethnologist to the first Peary North Greenland Expedition, which was read by invitation before the New York Obstetrical Society on January 16th.

The Eskimos who dwell between the seventy-sixth and seventy-ninth parallels live on the coast in a region of eternal ice and snow, are hemmed in by glaciers, can not therefore leave their locality, and have no regular communication with other portions of the world. They live on an absolute meat diet. Two thirds of this meat is raw and frozen and about one third is cooked. For nine or ten months of the year they are compelled to melt the ice or snow to get water to drink. They use no salt or condiment of any kind in their food—an exceedingly interesting fact. They do not bathe during their whole lives.

The average man is five feet one inch and a half in height, and his average weight is a hundred and thirty-five pounds, while the woman is four feet eight inches in height and has an average weight of a hundred and eighteen pounds. The men wear their hair as long as the women, and allow it to drop over their faces to protect them from the extreme cold. The muscular outlines of the body are nearly obliterated from the fact that they have immediately beneath the skin a layer of blubber or arcolar tissue which protects them against extreme cold. The least excitement among them will cause blood to flow freely from their mucous membranes, and a slight cut will bleed for an hour or two, showing, Dr. Cook thinks, that they are blessed with a supersbundance of blood.

The girls are marriageable when they are twelve or fourteen years old. The young men are usually ten years older. Although the girls attain their size early, they do not menstruate until the age of nineteen or twenty years. When a woman is about to give birth to a child she is put into a house and given frozen meat sufficient to last for two weeks and also some blubber and oil. If she survives the ordeal and the baby is heard to cry, the others will come in and help her; but if the baby's cries are not heard, that house will not be entered again. The common impression is, says Dr. Cook, that aboriginal women give birth to children easily, but it is not so with these women. Deaths in childbirth are not at all uncommon. From the histories he has obtained he has been led to believe that there are some cases of puerperal peritonitis, and the natural filth of the people, the author adds, would favor such a condition. The umbilical cord is severed with stones and is tied with a piece of dirty sinew.

<sup>\*</sup> Annals of Surgery, July, 1891.

During the whole of the long arctic night the secretions are diminished and the passions depressed, resulting in great muscular debility. The passions of these people are periodical, and their courtship is usually carried on soon after the return of the sun; in fact, at this time they almost tremble from the intensity of their passions, and for several weeks most of their time is taken up in gratifying them.

Their teeth are in good condition, though short and worn. During the arctic night the menstrual function is usually suppressed, not more than one woman in ten menstruating. The Eskimos do not consume so much oil as is generally supposed; they eat a good deal of fat as we do cheese, but not as a regular diet. Dr. Cook can not say why lactation continues so long (from four to six years). Among the northern tribes there is very little illness except rheumatism, occasionally follicular amygdalitis, and mild forms of la grippe, whereas further south not less than fifty per cent. of them have consumption. Every year there is an epidemic of la grippe that carries away thousands of the people in southern Greenland and Labrador. They have no system of medical treatment for their diseases. During the period of daylight menstruation recurs about every twenty-eight to thirty days.

THE INFLUENCE OF THE MEDICAL PROFESSION ON THE SOCIAL EVIL,

PROSTITUTION has existed practically since the world began, and it is highly probable that its termination and that of the world will coincide. A subject more wrangled over, more discussed, and more utterly defant of solution can not be imagined. It has vexed reformers and philanthropists ever since the world contained such men. It has had its defenders, too. Idealists and dreamers have theoretically trimmed it, and restricted it, and controlled it; lawmakers have practically outlawed it and then "regulated" it. And what has been the result of it all? Absolutely nothing. It continues, it flourishes, it even grows. Driven from its open and mercantile position by spasmodic and evanescent "revival" and "reform" movements, it but spreads in secret places only to break forth with renewed life when the reformer shall have grown tired of his hopeless task.

Are we, then, to accept the thing as necessary and consequently leave it to itself to grow and flourish unrestrained? Surely not. Necessary it may be, since evil and depravity seem necessities, but necessary in no other way; and as we fight other evils surely this too must be fought. How, then, shall this fight be carried on? Religion doubtless has aided and will aid, and the better education of the masses will do still more. From the law little can be expected; it may keep the evil from being publicly offensive, but, if it prohibits, it but scatters and does not care; if it "regulates" and "protects," it but encourages. There is one class of men whose power in this question is greater than that of all others—the physicians. Their relations with their patients and their influence over them enable them to be powerful either for good or for evil as they please,

and, if not actively for good, then are they passively for evil. But shall we make of each doctor a preacher and a missionary? How also can be do this good?

There is a well-founded idea in the popular mind, especially in the minds of young men, and one too often used as an excuse for debauchery, that coitus is necessary for health. Often, too, this idea is not only allowed by physicians to exist, but even encouraged, if not actively, at least passively. That coitus is not necessary for health is proved beyond doubt, not only by the highest medical authorities, but also by every man's powers of observation and common sense. That so erroneous and false an impression as that of the physiological necessity of coitus should prevail constitutes an affront to our professional dignity, and each one of us owes it to the profession and to himself to resent and destroy the imputation of complicity which it conveys.

This, then, is what we as physicians can do to help control the evil: We can collectively and officially declare that sexual indulgence is not necessary for health, and thereby destroy the possibility of the silly excuse so often given for depravity. Better yet, we can, each one, in his practice, use our efforts to destroy an impression so false and yet to the young so dangerous, while we point out the dangers and consequences so often the price of illicit venery.

#### MINOR PARAGRAPHS.

COMPRESSION OF THE UMBILICAL CORD DURING DELIVERY BY FORCEPS.

Dr. Swayne, the Lancet states, has recently again directed attention to the danger to which the child is exposed during delivery by forceps from pressure of the extremities of the blades on the umbilical cord, should it be so situated as to be compressed when the forceps has been applied. In a former communication on the subject Dr. Swayne instanced a hundred and fifty-three cases of forceps delivery. In twenty-three of these the child was either born dead or died soon after delivery; in four out of these twenty-three cases he attributed the death to compression of the cord by the forceps—that is to say, this injurious compression had been noticed in the proportion of once in thirty-eight cases. Since the time when this series of cases was published Dr. Swayne has had seventy-one forceps cases, with ten deaths of infants, and among these ten stillbirths there were two cases in which the child's death was due to pressure of the forceps on the cord. In this second series, then, the accident in question occurred once in thirtyfive cases-not very different from the frequency noted in the preceding series. Spiegelberg's estimate of the fœtal mortality in forceps cases is seventeen per cent. It certainly seems to be the fact, as Dr. Swayne says, that this particular danger-compression of the umbilical cord by the forceps-has not received perhaps so much attention as it deserves.

#### THE MICROBES OF SCORBUTIC GINGIVITIS.

A recent number of La Médecine moderne contains the result of Babès's latest experiments in this direction. The studies were made in three typical cases of scorbutus. Small portions of tissue from the gums, also specimens of blood, were submitted to microscopical and histological examination. There

was a diminution of the red globules, with marked leucocy. tosis. The microscope revealed a characteristic bacillus, elongated, thin, undulating, and forming thick masses. In the tissue the same colonies existed to such an extent as almost to form a false membrane. In connection with the peculiar bacillus numerous other bacteria were present, particularly a streptococcus. Inoculations of animals with the culture substance produced death with typical lesions of scorbutus. Autopsies and microscopical examinations disclosed the characteristic bacillus in great numbers in certain localities, such as the lungs and their capillaries, the tissue of the gums, and the viscera-They were not found in the hæmorrhagic effusions. The cultivation of the bacteria presented great difficulties on account of the presence of the streptococcus. It was found that an injection of the cultivation of streptococcus alone did not produce the typical disease, but with the suspected material from the scorbutic gingivitis death resulted from hæmorrhagic disease. Babès has not yet finished his experiments, but he is under the impression that the bacillus is one peculiar to the buccal region, and that in consequence of a depression in the general health these bacteria take on active changes producing the typical lesions. Again, it might be possible that the gingivitis was due to the presence of the streptococcus, and the general scorbutic symptoms to an invasion of the suspected bacillus through the mucous membrane.

#### THE PROGNOSTIC VALUE OF CREASOTE IN TUBERCULOSIS.

M. Burlureaux (Lyon médical) concludes from an extended observation that creasote is of greater diagnostic value than tuberculin. He has found that where patients can not tolerate creasote in never so small a dose they are usually beyond hope, but where they can support large doses their chances are good for complete cure. Where the drug is not tolerated the phenomena are very marked; directly after the injection the temperature begins to rise and increases for several hours, after which chilly sensations occur with a drop of the temperature to subnormal. All the other symptoms of poisoning with creasote are present. If the drug is borne no unpleasant features develop, but all the symptoms, such as fever, sweating, and so forth, of tuberculosis disappear, and the patients at once begin to improve. Intolerance of the medicament is the test of depreciation of the organism and deterioration of the vital powers.

#### ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 13, 1894:

DISEASES.	Week end	ing Mar. 6.	Week ending Mar. 13.	
DISEASUS.	Cases.	Deaths.	Cases.	Deaths.
Typhus	0	0	0	0
Typhoid fever	5	3	11	5
Scarlet fever	184	15	129	18
Cerebro-spinal meningitis	0	2	0	()
Measles	478	27	387	27
Diphtheria	203	52	167	44
Small-pox		3	23	3

The Paris Medical Faculty and the Anarchists.—"We are pleased to note in the pages of a contemporary," says the Lancet, "a refutation of the ridiculous statement lately published respecting the attitude of the medical faculty in Paris toward the convict Vaillant. It was suggested that the body

of the dead anarchist was buried, and, not as usual, conveyed to the dissecting room, because of a discreet desire on the part of our French confrères to avoid incurring the possible resentment of his sympathizers. This absurd insinuation has been cancelled by a later statement, which we are assured gives the true version of what occurred. Dr. Brouardel, who represented the profession, had not received timely notice of the execution, and consequently was not prepared to accept and make the preliminary examination of the body customary in the Paris school at the hour appointed. We are thankful for this later explanation. The disgraceful weakness implied in the canard at first circulated was certainly unworthy of any civilized community, and must have caused a feeling of painful surprise among members of the profession in this country. Whatever may be said as to the disputed question of capital punishment in this case, the determined attitude of the French Government in dealing with such outrages as that of the miserable bomb-thrower deserves, and, we trust, will obtain, the firm and undoubting support of every patriotic citizen."

The Harvard Medical School.—This school is the recipient of a bequest, valued at \$50,000, under the will of the late Rev. Charles Moseley, of Newburyport.

Bellevue Hospital.—Dr. William P. Northrup was recently elected by the faculty of Bellevue Hospital Medical College to be adjunct professor of diseases of children.

The Ohio Medical University held its commencement exercises on the 13th inst. in Columbus.

The Alumni Association of the College of Pharmacy of the City of New York.—At a meeting held on Wednesday evening, the 14th inst., Professor H. H. Rusby gave a lecture entitled The Observations of a Pharmacognosist in England.

The Medico-legal Society.—At the last meeting, on Wednesday evening, the 14th inst., Judge L. A. Emery, of the Supreme Court of Maine, was to read a paper entitled Medical Witnesses; and Dr. A. E. Osborne, of California, one entitled People who Drop out of Sight.

The Bill for the Relief of Acting Assistant Surgeons in the Army, now before Congress, applies, we are informed, to those who were appointed after the close of the late war.

Change of Address.—Dr. A. J. McCosh, to No. 22 East Fifty-sixth Street.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from February 25 to March 10, 1894:

IEWIN, BERNARD J. D., Colonel and Assistant Surgeon General, is granted leave of absence for twenty days, to take effect upon the adjournment of the Eleventh International Medical Congress, to be held at Rome, Italy, March 29 to April 5, 1894.

A board of medical officers, to consist of Corson, Joseph K.,
Major and Surgeon; Reed, Walter, Major and Surgeon; and
Cabell, Julian M., Captain and Assistant Surgeon, is by direction of the Secretary of War appointed to meet at the call
of the president thereof at the Army Medical Museum Building in Washington for the examination of Wales, Philip G.,
First Lieutenant and Assistant Surgeon, to determine his
fitness for promotion. Lieutenant Wales will report in person to the president of the board at such time as he may designate.

Beall, George T., Captain and Medical Storekeeper. By direction of the President his retirement from active service on the 25th of February, 1894, by operation of law under the provisions of the act of Congress approved June 30, 1882, is announced.

ROBERTSON, REUBEN L., Captain and Assistant Surgeon. The leave of absence granted is extended one month.

BROOKE, JOHN, Major and Surgeon, is retired from active service, February 22, 1894.

Heyl, Ashton B., First Lieutenant and Assistant Surgeon, is relieved from duty at Fort Niobrara, Nebraska, and ordered to Columbus Barracks, Ohio, for duty at that depot, on the arrival of Bratton, Thomas S., First Lieutenant and Assistant Surgeon, at Fort Niobrara, Nebraska.

Ball, R. B., Captain and Assistant Surgeon, Fort Monroe, Virginia, is hereby granted leave of absence for one month.

Johnson, R. W., Captain and Assistant Surgeon, will proceed to Fort Monroe, Virginia, for temporary duty during the absence on leave of Captain R. B. Ball, Assistant Surgeon. Upon the return of the latter from leave, Captain Johnson will return to his station, Washington Barracks, District of Columbia.

WILLOX, CHARLES, First Lieutenant and Assistant Surgeon, is relieved from temporary duty at Boisé Barracks, Idaho, and ordered to return to his proper station, Presidio of San Francisco, Cal. Par. 7, S. O. 54, Headquarters of the Army, A. G. O., March 5, 1894.

WILCOX, TIMOTHY E., Major and Surgeon, is granted leave of absence for one month.

Hall, John D., Major and Surgeon. The leave of absence granted is extended one month.

RAYMOND, HENRY I., Captain and Assistant Surgeon, is granted leave of absence for four months, to take effect on or about August 10, 1894.

HOFF, JOHN VAN R., Major and Surgeon, is hereby assigned to the charge of the office and duties of the Medical Director, Headquarters Department of the East, during the temporary absence of SMITH, JOSEPH R., Colonel and Assistant Surgeon General, Medical Director of the Department.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the week ending March 10, 1894:

OLCOTT, F. W., Passed Assistant Surgeon. Detached from the
Naval Hospital, New York, and ordered to the Richmond.

White, S. S., Passed Assistant Surgeon. Detached from the Richmond and ordered to the Naval Academy.

Curtis, L. W., Passed Assistant Surgeon. Detached from the Naval Academy, Annapolis, and to wait orders. Lumsden, G. T., Passed Assistant Surgeon. Detached from the

Kearsarge and to wait orders.

Jones, W. H., Medical Inspector. Ordered before the Retiring Board.

Riges, C. E., Assistant Surgeon. Detached from the Naval Hospital, Mare Island, California, and ordered to the Naval Laboratory and Department of Instruction, New York.

Bertolette, D. N., Surgeon, and Moore, J. M., Assistant Surgeon. Ordered to the Atlanta.

Page, J. E., Assistant Surgeon. Ordered to the examination preliminary to promotion.

#### Society Meetings for the Coming Week:

Monday, March 19th: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

Tuesday, March 20th: Florida Medical Association (first day— Tampa); New York Academy of Medicine (Section in General Medicine); New York Obstetrical Society (private); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.

Wednesday, March 21st: Florida Medical Association (second day); New York Academy of Medicine (Section in Public Health, Hygiene, and Vital Statistics); Harlem Medical Association of the City of New York; Medical Society, New York; Northwestern Medical and Surgical Society of New York; Medical Society of the County of Allegany, N. Y. (quarterly); New Jersey Academy of Medicine (Newark).

THURSDAY, March 22d: New York Academy of Medicine (Section in Obstetrics and Gynacology); New York Orthopedic Society; Brooklyn Pathological Society; Roxbury, Mass., Society for Medical Improvement (private); Pathological Society of Philadelphia.

FRIDAY, March 23d: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

Saturday, March 24th: New York Medical and Surgical Society (private).

## Wetters to the Editor.

A CASE OF DIPHTHERIA PRECEDED BY UNUSUAL SYMPTOMS.

Depew, New York, February 23, 1894.

To the Editor of the New York Medical Journal:

SIR: I was called to see R. McL., aged seventeen months, on Monday, January 29, 1894, his illness dating from Friday, January 26th, and found him suffering from an attack of acute tonsilitis. Temperature, 104.6°; pulse, 140. Physical examination failed to elicit any pathological condition in the lungs. In the evening, under routine treatment, the temperature had dropped to 99° and the pulse to 100. I told the parents it would be unnecessary to call again as he would be better in the morning, advising them as to the subsequent care necessary in order to prevent a relapse.

In the morning, as stated to me by the parents, he was so well that he was crying to get up and be dressed and allowed to play around the floor and run out into the cold, with the result that when called in the evening I found a temperature of 105° and a pulse of 150; respirations, 50. Every symptom of an extension into the bronchial tubes and a beginning of broncho-pneumonia.

Treatment was at once instituted, and the following days up to Friday showed some little improvement in his condition, the temperature ranging from 102.6° to 103.2° F.

Friday morning his temperature was 104° and there was great difficulty in respiration, the bronchial tubes being filled with mucus, large bubbling râles being distinguishable at a distance of fifteen feet. I administered an emetic—turpeth mineral—with the result that nearly ten ounces of viscid mucus was vomited. The respirations were now much easier and the child sank into a quiet sleep.

In the afternoon I found the temperature still high, the skin hot and dry. Cold sponging and alcohol baths having proved inefficient in the reduction of the temperature, I determined to reduce it by inducing a free diaphoresis.

I communicated my wishes to the mother, who was holding the child, at the time presenting a good appearance, eyes bright and cheeks red. She, to assist me, laid the child down, and M.

after she had it comfortably fixed remarked that he was sweating. This did not occupy three minutes' time. I hastened to him and found him sweating, true enough, but a sweat of collapse, cold from head to foot, pulse imperceptible. I immediately stimulated and gave a hot bath, wrapped him in hot blankets, and stimulated the heart's action by a hypodermic injection of nitroglycerin; he was so low I thought it impossible to hold him until his father arrived.

In the evening he revived a little; the pulse was now perceptible, 200; respirations, 90; but it seemed impossible that he could live the night through. On the following day the condition was hardly changed—pulse 200, feeble and thready; respirations, 86. On Sunday there was a slight improvement—pulse, 160; respirations, 78, and temperature, 1014°.

On Monday morning, on examination of the throat, I found the tonsils, the anterior pillars of the fauces, and the pharynx covered by a membrane, coalescent and adherent—the case had developed into diphtheria. A little heroism was necessary here, and I pushed the stimulation to the verge of excess. I administered a teaspoonful of brandy every hour in a little milk, and gave the following prescriptions along with it:

R Potas. chlor	gr. xxiv;
Tinct. ferri chlo	3 jss.;
Glycerin	3j;
Aquæ q. s. ad	3 ij.
Sig.: A teaspoonful every hour.	
And B. Quin. sulph	gr. xxxij
Ac. sulph. dil	3 j;
Tinct. digitalis	mχvj;
Aunge ad	7 ii

M. Sig.: A teaspoonful every hour.

The throat was sprayed every third hour with a seventy-five-per-cent. solution of peroxide of hydrogen, and the nose with a twenty-per-cent. solution.

I administered also every third hour two grains of salol, and imagine I owe much to this drug for the child's life, by its antagonizing the poison swallowed every few minutes by the little sufferer.

On Tuesday the throat symptoms were the same, the respirations still very rapid, 68 to the minute; pulse, 150; temperature, 101°.

On Wednesday there was no amelioration of the throat symptoms. The peroxide proving ineffectual to dissolve the membrane, to two ounces of a fifty-per-cent. solution of peroxide I added about ten grains of Fairchild's pepsin, and on the following day, after frequent spraying, the throat was nearly free from membrane.

On Saturday, February 10th, the child was convalescent, and is now nearly recovered.

The reason for the writing of this article is to elicit from the profession opinions as to the true nature of the disease, and to obtain some hypothesis as to its true pathology.

Certainly it is unusual for a case of capillary bronchitis to be complicated by diphtheria.

For a résumé: The temperature, pulse, and respirations, together with the physical examination, which revealed scattered areas of dullness in both lungs, with subcrepitant râles and later large bubbling râles, denoted a broncho-pneumonia, but strangely it was not associated with much coughing.

The collapse of Friday was a toxemia and not the asphyxia usually attendant on broncho-pneumonia, and, as I have remarked before, it is very unusual to have the disease complicated by diphtheria.

I have been sometimes tempted to believe that the case was one of diphtheritic laryngitis with an extension upward, but this is unsatisfactory and does not account for the lung symptoms,

the subcrepitant and large bubbling râles. All symptoms of a diphtheritic laryngitis were wanting.

Is broncho-pneumonia ever accompanied by the formation of a false membrane, non-diphtheritic, coalescent, and adherent, situated upon a deeply injected mucosa? And, if so, would it be accompanied by swelling and tenderness of the cervical glands?

I should be much pleased to hear from some members of the profession of cases similar and explanatory as to the nature of the case here presented.

F. H. Field, M. D.

#### CHLOROFORM IN CORYZA,

219 S. Seventeenth Street, Philadelphia, March 12, 1894.
To the Editor of the New York Medical Journal:

Sig: In the Journal of the 10th inst. I notice a paragraph in which Dr. J. Gerard recommends the use of inhalations of chloroform in arresting the extension of coryza to the bronchial tubes.

If you will kindly refer to the first edition of Dr. J. Solis-Cohen's book on *Diseases of the Throat*, published in New York, 1872, page 256, you will find chloroform recommended, with its advantages and its risks expressed as follows:

"The inhalation of chloroform to the induction of anæsthesia, administered after the patient has been put into bed, will often be found adequate to abort a cold by its relaxing influence upon the structures, which are in a state of tension. Personal experience has proved the value of this remedy in a number of instances, especially in such as were thought too far advanced to promise success in the abortive treatment by opium or alcohol. But while the use of the anæsthetic is acknowledged to be efficient for the purpose, the responsibility of a resort to it must rest upon the physician prescribing it. It is in some respects a dangerous remedy, and one to be employed in skillful and careful hands only, and therefore not to be generally recommended. But such happy effects have followed its use in the author's hands in some cases attended by intense pain and tension in the frontal and maxillary region, and presenting distressful obstruction to breathing, that an acknowledgment of its value is not to be withheld. The cases alluded to would have required larger doses of narcotics to control their symptoms than it was deemed desirable to prescribe; and the fact was remembered that the administration of chloroform for the relief of pain already existing is by no means attended with anything like the same danger as when it is given for the prevention of pain. An examination into the statistics of deaths from chloroform will show that this result rarely happens when it is judiciously administered for the relief of pain, as in neuralgia, parturition, and operations begun without resort to anæs-SOLOMON SOLIS-COHEN, M. D. thesia."

#### SOME SERIOUS OVERSIGHTS.

Berkshire, Mass., March 1, 1894.

To the Editor of the New York Medical Journal:

Six: The great development of medical science in all directions during the present generation seems to have cultivated a tendency to verbosity in medical writers which is prejudicial to the general advancement of knowledge. Simplicity in scientific writing is very desirable on every account—it is eminently conducive to perspicuity, "the first requisite of style."

In this respect a certain text-book is disappointing. The list of its contributors contains the names of men who are eminent in our profession; but these writers have obscured their essays with too complicated constructions, making it needlessly laborious to get at their meaning. If they had simplified their

style two volumes of much smaller size than these bulky ones might have contained all they have given us.

There is a certain disadvantage in the work being made up by a number of scholarly writers, who all endeavor to maintain a high standard of composition in view of the competition —and overdo it. Whereas, had it been the work of a single author, he would have aimed at brevity and presented the subjects in the manner most readily assimilated by the student.

But it is not only in style that the work is somewhat disappointing. I subscribed for it, hoping to get a text-book for easy reference, that would contain the most advanced pathology, and therapeutics. But in several of the chapters that I have examined there is a notable deficiency in this respect.

Pneumonia the author defines as "an infectious inflammation, with exudation from the blood-vessels and the growth of pathogenic bacteria," and makes no distinction between simple and infectious lobar pneumonia. He says "the mortality has gradually increased from ten per cent. in the first decade (1822 to 1832) to twenty-eight in the present decade," and gives several reasons for the increase, but makes no reference to diphtheria as the essence of infectious pneumonia and the cause of increased mortality. Single uncomplicated lobar pneumonia, before the appearance of diphtheria in this country in 1857, was never fatal under good care, and infection in any case was unknown. In regard to therapeutics, the eminently successful treatment of simple pneumonia with carbonate of ammonium, under which its period was shorter than by any other treatment, is not mentioned by this author.

In the consideration of the treatment of acute dysentery, no mention is made of what Bartholow, in his Materia Medica and Therapeutics, says is the best method, "the most efficient treatment"—that by sulphate of magnesium in frequently repeated doses—although this method has been advocated since 1852, and was somewhat widely employed before Bartholow indorsed it. The London Lancet several years ago published a report from an East India surgeon, of ninety-five cases treated in this way in India by him in one season, with rapid cure, without a death—except in one case admitted to his hospital in an advanced stage. The writer reported that he had adopted the treatment on Bartholow's suggestion.

In puerperal convulsions it has been known for twenty years that veratrom viride, in doses large enough to reduce the pulse below the normal rate, arrests the paroxysms, and by all experience has a marked superiority to all other methods. It has been published in New York and in Canada, if not elsewhere; but no mention is made of it in this book.

In the chapter on cholera, no mention is made of the use of calomel, as the main reliance in the treatment during the first stage; although by all experience in two of the epidemics it was the chief reliance. "The calomel treatment was pursued in the four cholera hospitals of New York and Brooklyn in 1866, with about the same results in all. It met with favor in Europe and in the United States army. In 1854, Dr. Hutchison, who treated a hundred and forty-four cases in the Brooklyn hospital, made no attempt to check the diarrhea, but gave a grain of calomel every hour; and all those who entered the hospital in the first stage recovered." This was the common experience.

The chapter on diphtheria fails to notice the important fact that the false membrane is not in all cases visible in the throat —a very serious consideration, in view of diagnosis and treatment. This was an observation made some years ago by the late Dr. W. P. Seymour, of Troy, N. Y., and fully set forth in the New York Medical Journal in 1889. It was there stated that "diphtheria is to be regarded as a constitutional disease, manifesting itself upon any mucous membrane, and frequently

exhibiting no exudation membrane on the fauces, while attacking the lungs or other organs; that the diagnosis does not depend upon the presence of a false membrane in the throat."

Whether these important omissions are characteristic of the entire work, I can not say, for I have not yet examined other chapters. For the faults of style, the redundancy of language, I think that the present fashion of bacteriological studies is partly responsible—by their elaborate details, whose value is overrated. For we know that that part of microscopic history has no bearing upon therapeutics, except so far as it aids in the diagnosis of zymotic diseases. William Henry Thayer.

#### MAUNSELL'S METHOD OF CIRCULAR ENTERORRHAPHY.

55 West Thirty-sixth Street, March 12, 1894.

To the Editor of the New York Medical Journal :

Sir: The following extract from a letter recently received by the writer from Professor H. Widenham Maunsell, of London, will interest your readers: "In the discussion of your paper, A Case of Contusion and Rupture of the Heum, the following remarks occur: 'In addition to Maunsell's method the use of a single row of sutures, either continuous or Lembert's interrupted sutures round the outer layer uniting the peritoneal surfaces, would be a great safeguard.'

"Answer.—A double line of sutures should never be applied in intestinal surgery. It obstructs the circulation too much, interfering with firm plastic peritonitis and in some cases causing gangrene of the inverted portion of gut. A continuous suture should never be applied round the intestine. First, the diameter of the intestine is always varying; second, as the stitches never cut out simultaneously, they would form loops inside the intestine which would be liable to catch or be dragged or torn out by the onward movement of the contents of the bowel."

#### WHO SHOULD TEACH IN OUR MEDICAL COLLEGES?

CLEVELAND, O., March 7, 1894.

To the Editor of the New York Medical Journal:

Sir: It is surprising to note in visiting our medical colleges the number of important chairs filled by foreign instructors who can not express themselves intelligibly in English.

When I attended lectures I met with the misfortune of hearing for ten months a professor in physiology who could not halfway express himself.

Students could not understand him or he the students. He understood his subject, but could not impart it. The all-important thing for medical students is not imported instructors, but good, simple, well-expressed instruction put in English.

It matters not how much a man knows if he has not the key (the English) to unlock bis thoughts to the student. The poor student must suffer. The instructor had better know less and be able to impart more.

I met with a medical society not long ago. An able paper was presented by an American. A discussion followed. Previous to the discussion some member had the audacity to call forward a distinguished physiologist (as he called him) to take up the physiology of the subject. After he had completed his talk we could hardly tell whether we had listened to a talk on physiology or upon the weather. This man is an instructor in physiology in a medical college of a hundred and fifty students. It is an imposition for students to have to listen to such a man. Students pay their money and they should demand intelligible instruction.

PRACTITIONER.

"SHOULD PHYSICIANS CHARGE EACH OTHER FOR MEDICAL SERVICES?"

February 26, 1894.

To the Editor of the New York Medical Journal:

Six: I was interested in the quotation you make from the \*Medical News\* under this heading, because of a recent experience which has, to me at least, a funny side. My daughter, at college in an Ohio town, was attacked with influenza. Informed that Dr. A. was "the best physician," he was promptly summoned, and after two weeks' illness the patient recovered. I wrote to the doctor, who promised to inform me if any serious symptoms presented. On my daughter's return home, a bill was brought to me made out at the regular rates, and also the information, now for the first time received, that the attending physician was a homeopath, a fact not known until he had been in attendance for several days, when the patient could not summon sufficient courage to dismiss him.

What makes the incident somewhat amusing is this: In a presidential address to the State Medical Society, when speaking of "the demands of modern medicine," I used this language: "Third. No advance in medical knowledge worth striving for can be attained, if the physician limits the horizon of his vision by erecting the barrier of some exclusive dogma. With the liberal culture here called for, we need not fear that the modern physician will be lured into a pursuit of that ignis fatuus, similia similibus curantur, or that the fancied 'potency of dilutions' will charm him into forsaking the mathematical demonstrations of his youthful days. Modern medicine demands that he shall rise above such delusions. Nor is it becoming in the cultured physician to place some catch-word upon his sign with which to dupe the unwary, while at the same time he in serious cases resorts to rational therapeutics, discarding his sugar pellets whose sweetness has won him practice."

And in a recent address I took occasion to quote from Dr. Weir Mitchell the following illustration of the universal good-fellowship among physicians: "From Japan to London you may claim medical attendance for self or wife or child, and find none willing to take a fee. There is something fine in this idea."

Entertaining sentiments such as these touching homocopathy and professional generosity, fancy my feelings when told that my daughter had not only been attended by a homocopath, but that I must foot the bill! To say that I was mad is putting the case mildly, but doubtless my homocopathic brother will exclaim, "It serves him right!"

MAD Doc.

# Proceedings of Societies.

SOCIETY OF THE ALUMNI OF BELLEVUE HOSPITAL.

Meeting of February 7, 1894.

The President, Dr. FREDERICK H. WIGGIN, in the Chair.

Extreme Rhachitic Deformity.—Dr. Parker Syms presented a case of this kind. C. H., a colored boy, eighteen years of age, had been admitted to the Colored Hospital on February 17, 1890. His family history had been negative. He had been deformed since childhood, but had enjoyed good health. His limbs were very much distorted.

Syphilitic Exostoses.—Dr. Syms also presented a colored man, twenty-eight years of age. He was single, and a laundryman by occupation. He had been admitted to the Colored Hospital on January 8, 1894. His family history had been

negative. He had had the ordinary diseases of childhood. The present affection had begun about five years ago with a swelling of the ankle and an aching pain on motion. The following year sores had appeared on the arm, on the back of the neck, and in various other places, and these sores had discharged creamy pus. About a year ago both wrists had begun to swelland had continued to increase in size up to the time of his admission to the hospital. On admission he had been well nourished and in good condition; the wrists had been very much enlarged, the right wrist being nine inches in circumference. The swelling had been of stony hardness; it had involved both the radius and ulna and had extended upward about four inches. It had been painful to the touch. The lower end of the right tibia had also been enlarged, so that it had measured ten inches in circumference. The shaft of the tibia in the middle third had been nodulated, and on the left leg there had been some swelling and nodulation over the middle third.

Dr. I. S. Haynes said that in the dissecting room it was not uncommon to find bones presenting similar deformities, especially in the case of the tibia, radius, and ulna; and on section their structure was observed to be very dense, and the medullary canal almost or entirely obliterated.

Submucous Fibroma of the Uterine Body; Enucleated without Morcellation .- Dr. W. EVELYN PORTER presented such a specimen. The tumor measured fourteen and a half by eleven and a half inches in circumference. The patient, fortythree years of age, had been married twenty-three years, and had had seven children, the last five years ago. Labor in each instance had been normal. Menstruation prior to two years ago had been regular and unaccompanied by pain. During the past two years she had suffered from gradually increasing menorrhagia, the periods at times lasting from six to fourteen days, accompanied by more or less pelvic distress and sense of weight. She had been unaware of the existence of a tumor until a month before, when she had been examined by her family physician. When first seen by the speaker she had been extremely anamic and weak, although fairly well nourished. Examination had revealed a uterus considerably enlarged, irregular in outline, with a mass of about the size of an orange protruding from the cervix. Examination of this mass had caused quite profuse hæmorrhage. Upon admission to the New York Cancer Hospital she had been prepared for operation, and after consultation with Dr. Outerbridge and Dr. Coe it had been decided to remove as much as possible of the growth per vaginam. When she was examined under ether anæsthesia there had appeared to be two separate masses, the smaller one extending into the vagina, and the other well up into the uterine cavity. The lower one had seemed to be attached by a broad pedicle to the left side of the uterus. It had been held firmly and drawn down with heavy forceps, while the very dense adhesions to the uterine wall were being separated. It had soon been discovered that the mass was continuous with the larger one above, and further dissection had shown that what had been supposed to be the pedicle on the left side had been part of the growth adherent to the uterine wall. This had been freed by careful dissection with the finger and scissors. No large vessels had been found. The entire tumor had finally been enucleated in this manner without injury to the uterine wall and removed through the vagina, a few bleeding points had been ligated, and the uterus, which had been inverted, had been reduced and its cavity packed with iodoform gauze. Recovery from the anæsthesia had been prompt, there had been no hæmorrhage, and the gauze had been removed on the following day. Quinine and ergot had been given to favor involution. The patient was at present convalescing, and would in all probability completely recover.

Ovarian Cvst: Coliotomy: Recovery.-Dr. PORTER also reported such a case. L. A. S., twenty-three years of age, married two years and a half. Family history negative. She had had two children and no miscarriages. Five years ago her health had been excellent. At about that time she had begun to suffer with severe lumbar pain and dysmenorrhea. From that time on menstruation had become more and more profuse, lasting from ten to fourteen days. Nine months ago she had consulted a physician who had told her that she had no ovarian disease, but that she had "inflammation of the womb" which could be cured by local applications. She had been under treatment for more than six months, during which time she had steadily grown worse. When first seen by the speaker, on December 13th, she had been much emaciated and anæmic, and there had been a soft, fluctuating tumor of about the size of a child's head to the right of the uterus. A small mass could also be felt on the left side. The uterus itself had been normal. Operation bad been advised, and after improving her general condition somewhat this operation had been performed on January 6, 1893. The tumor had been found to be a thin-walled ovarian cyst, and it had been removed without difficulty. The opposite ovary had been cystic and had also been removed. Recovery from the operation had been prompt, and the patient was sitting up at the end of the second week. At present she was entirely relieved of the pain, and was rapidly gaining in health. The case was of interest from the fact that the extreme degree of fluctuation and the very thin walls of the cyst had rendered the diagnosis difficult.

Symphysiotomy.-Dr. J. C. Edgar presented two patients upon whom he had performed this operation. The first patient had been operated upon ten months and a half ago. She was a primipara, in good general condition. When first seen she had been in labor forty eight hours and the membranes had been ruptured artificially five hours before. There had been a vertex presentation, with the sagittal suture transverse in the pelvis. The diagonal conjugate diameter had measured four inches, from which it had been estimated that the true conjugate was three inches and a quarter. An attempt had been made to engage the head by suprapubic pressure combined with internal manipulation. This being found impossible, an axistraction forceps had been applied and moderate traction made, but the head had not engaged. While traction was being made meconium had appeared in the vagina. The question of version or symphysiotomy had then come up. Symphysiotomy had been elected as giving the child a better chance for its life. It had been performed according to the usual manner—the parts had been shaved and cleaned as for a laparotomy, the patient had been placed in the dorsal position, and a male sound had been passed into the bladder and the urethra held over to the left side. An incision had been made directly upon the pubes and the symphysis had been found distinctly to the left of the median line. Section of the joint had been made with a curved bistoury. No hæmorrhage of importance had occurred. The trochanters had been supported laterally by the hands of an assistant. Immediately on cutting through the joint and subpubic ligament there had been a separation of an inch and a quarter by actual measurement, and this had probably been still further increased during the subsequent version. Direct podalic version had been performed, and the child had been immediately extracted. It had been asphyxiated, but had been resuscitated, and was now alive. Silk sutures had been introduced, two including the fibrous tissues over the joint. No drainage had been used. Care had been taken that the bladder and urethra were not included between the bones. Strips of rubber adhesive plaster and a tight bandage had been applied around the pelvis. The highest temperature had been 100.8°

and the highest pulse 100. She had been kept in bed twenty-eight days, and a binder had been kept on for five weeks. The child had been a male and had weighed seven pounds. The bi-parietal diameter had been three inches and a half, and the true conjugate diameter of the pelvis three inches and a quarter. This had been the sixth symphysiotomy done in New York. There was some motion still in the joint, but it was perceptible only when the patient stood first on one foot and then on the other and swayed from side to side.

The second patient was a primipara, nineteen years of age, who had been operated upon on November 8, 1893. She had been in labor for fourteen hours when first seen, and the head had not engaged. The true conjugate had measured three inches and a quarter. In this case the os had only admitted two fingers; hence, after etherization, the os had been fully dilated by manual force, and then internal direct version practiced, followed by immediate manual extraction of the child. The child had weighed seven pounds and a half, and the biparietal diameter had been three inches and a half. The incision had been made in the same way as in the first case, except that it had been about half as long-an inch and a half. There had been very profuse venous hæmorrhage after section of the joint in this case, which had required to be controlled by iodoform gauze packing. Silk sutures had been used-three, including the fibrous tissues over the joint, and in addition to rubber plaster a plaster-of-Paris bandage had been placed around the pelvis, which had been replaced by another in two weeks. It had been rather more cleanly than the dressing used in the first case. In this case the first stage had been fourteen hours, the second stage twenty-five minutes, and the third stage ten minutes. Her pulse had been 110 at the completion of the operation. There had been no rise of temperature over 100° F. until the eighth day, when there had been a chill and the temperature had risen to 104° F. Examination had shown that the plaster bandage had been applied so tightly that it had caused contraction of the lower segment of the uterus and had thus interfered with drainage. The uterus had been washed and curetted, and an iodoform-gauze tampon introduced. The temperature had immediately fallen and remained normal thereafter, hence the temperature had probably been due to selfinfection. She had been kept in bed for four weeks and had then been allowed to get up.

Dr. R. C. M. Page asked if there might not have been slight motion at the symphysis independently of such an operation?

Dr. Edgar replied that he had examined a number of women in hospitals and had found that there was such motion before confinement. This last case had been the thirtieth symphysiotomy in the United States. He had done the operation two weeks before in a case of justo-minor pelvis. Even with the symphysiotomy and the consequent separation of bone in this last case the child had been extracted with the utmost difficulty on account of the contracted transverse diameter, and the version had caused a rent in the cervix extending up into the left broad ligament.

Dr. Murray, Dr. Goldthwaite, and Dr. Barrows were appointed a committee to examine these cases of symphysiotomy and report on the patients' condition.

Dr. GOLDTHWAITE said that he had observed almost us much motion in women pregnant at the eighth month as was to be found in these cases. He thought it was remarkable that the operation of symphysiotomy had been so long unrecognized by the profession.

Dr. Barrows said this was the fifth case of symphysiotomy he had examined, and there was much less motion here than in the others. In the first cases the patients had been permitted to get up on the twentieth to the thirtieth day, and he thought at the time that the greater motion in them had been due to their early getting up, but this theory has been upset by these two cases just presented in which the stay in bed had been about the same.

Dr. R. A. MURRAY reported that there was very little motion in either patient, and that it in no way interfered with their going about. He had now seen three symphysiotomies and six or seven patients after the operation. In the cases under discussion the children had only weighed about seven pounds-in other words, had been rather small. He thought very much depended on the size of the child compared with the amount of contraction of the pelvis in these cases. In these cases the diameter had been only half an inch less than what would have allowed of the passage of the parietal bone without compression, so that delivery by version might have been possible, although, of course, with very great risk to life. When the child's head was very large and the contraction of the pelvis marked, the separation at the symphysis must be so great as to endanger the integrity of the sacro-iliac synchondrosis, and this might have something to do with the amount of motion found afterward. In a very large proportion of the cases reported the child had been rather small. He believed the operation had a great future before it, for it afforded an opportunity to deliver of a live child in case of a bad presentation. Thus there were many cases of impacted occipito-posterior positions in which this operation would be the means of saving the children. This view distinctly broadened the field of the operation. He was an advocate of the elective Casarean section, yet there were many cases in which consent could not be obtained for this operation when symphysiotomy might be done with satisfactory results.

Dr. Edgar said that most German authorities were agreed that if the separation of the joint exceeded an inch and a half there was danger of rupture of the sacro-iliac ligament. Last summer he had seen in the Baudeloque Clinic in Paris some beautiful sections of the pelvis taken from the frozen cadaver, showing a separation of an inch and a half to two inches, and still absolutely no rupture of the sacro-iliac ligaments. He believed that Zweifel and others were of the opinion that if the separation reached two inches there was great danger of rupture of the sacro-iliac ligaments, and that this would prove a serious matter.

Small-pox and Measles.—Dr. S. T. Hubbard referred to a recent experience in the City Hospital. On January 18th a patient with small-pox had been removed from one of the wards in the hospital, and fourteen days later another patient in the same ward, who had come from the same house in the city, had been taken sick. The suffusion of the eyes and the nasal discharge and eruption had pointed toward measles, but it had been thought best to isolate the patient and wait for further developments. The temperature next morning had fallen very considerably and the eruption had been fading, so that there could no longer be any doubt of it being a case of measles. He reported the case simply on account of the doubt as to the diagnosis between small-pox and measles during the first twenty-four hours.

 $(\ To\ be\ concluded.)$ 

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Eighty-eighth Annual Meeting, held in Albany, on Tuesday, Wednesday, and Thursday, February 6, 7, and 8, 1894.

The President, Dr. HERMAN BENDELL, of Albany, in the Chair.

(Continued from page 312.)

Disputed Points in Pelvic Surgery.—Dr. Joseph Price, of Philadelphia, opened a discussion on abdominal surgery

with a paper thus entitled. He believed that there was still great uncertainty in the profession at large as to what should and what should not be done surgically in the pelvis, notwithstanding the fact that great changes and developments had taken place in this field. The old theory of cellulitis had been exploded by the investigations of Bernutz and Goupil.

There had been much bad reasoning from improper premises concerning pelvic surgery. Tubal and ovarian abscess had been regarded by some writers as a condition which was not especially dangerous, but it was possible to observe the question from two different standpoints—that of immediate danger and that of prolonged ill health with all its accompaniments. Unfavorable opinions concerning the surgery of the pelvis had often been given by so-called conservatives whose experience in this direction was limited and not very successful. Advice from this source was useful only in so far as it deterred incapable and inexperienced men from operating. The complications of pelvic surgery were among the most trying which could be imagined, and called for the highest order of skill and judgment.

Radical treatment of the conditions encountered was preferable in all cases in which it was possible. Too much should not be expected from such operations as were under discussion; they should not be expected to restore all physical functions which had been lost. The extirpation of the entire genital apparatus for the mere suspicion of disease was very rash treatment. Pus in the pelvis was objectionable under any circumstances, and should be got rid of if possible. The chief causes of pelvic suppuration were gonorrhoma and dirty midwifery.

Serious lesions of the abdominal viscera were very frequent concomitants of pelvic disease, and always added greatly to the gravity of the situation. Common sense should be the guide in all these forms of disease as in all other forms of surgery.

Influences affecting the Results of Abdominal Operations .-- Dr. J. F. W. Ross, of Toronto, continuing the discussion, remarked that patients who had been subjected to unfavorable influences prior to operations often died, while others equally diseased, but with better surroundings and preparation, recovered. The factor of individual resistance was also of great importance in determining the result of an operation. Those who were enfeebled by constitutional vices, such as tuberculosis, syphilis, etc., were prone to succumb to operations, and the wisdom of operating in such cases was often open to question. The result of operations was also modified by the character of the disease. Simple operations in patients in whom suppuration was absent should rarely result in death; but suppurative cases must often result fatally, however skillful the operation or excellent the surroundings. The result was modified, too, by the surroundings and by the purity of the atmosphere in the patient's immediate neighborhood. Cleanliness was more important than antiseptics of whatever character. It sometimes appeared that a comparatively healthy peritonæum was more susceptible to infective influences after operation than one which was diseased. The routine use of purgatives after operations was not altogether safe practice. Drainage did not always accomplish the results which were expected, and this signified imperfections in the mode of operating. Hæmorrhage should seldom be feared if the operation had been carefully enough performed.

Hæmorrhage after Abdominal Section; its Place in Statistics.—Dr. A. H. Buormaster, of New York, followed with a paper in which he said he thought that accidents of this character were relatively frequent and that they were seldom re-

ported. Hence the statistics of the subject were not especially reliable. The number of operations which had been done by a gynæcologist was not necessarily a standard for judgment as to the operator's skill. Hæmorrhage of a serious character might occur several days after the performance of operations of not very great magnitude, thrombi which had formed having broken down. Instances of such a character were narrated as following trachelorrhaphy. The speaker had recently lost a patient from secondary hæmorrhage, and had collected accounts of twenty-two cases with similar results. There were few operators of large experience who had not lost one or more patients in that way. The Trendelenburg posture contained an element of danger in the fact that blood lost during an operation gravitated toward the diaphragm and might be overlooked. In some cases the hæmorrhage did not begin until after the person was lowered to the horizontal posture.

Cysts of the Epigastrium.—Dr. D. P. ALLEN, of Cleveland, narrated the histories of two cases in which he had operated for supposed cyst of the pancreas. In the first case the tumor lay between the stomach and the transverse colon, and examination of its contained fluid revealed nothing but blood. Shortly afterward the patient became pregnant, and just before the termination of pregnancy was seized with vomiting and collapse, and died. A cyst was found in the abdominal cavity containing a large quantity of bloody fluid.

The second case occurred in a boy, and the tumor lay above the stomach. An abdominal incision was made, the tumor was emptied of its contents, and the edges of the incision in the sac were stitched to the edges of the abdominal wound. The fluid in this tumor contained cholesterin and emulsified fat, but no trypsin. The situation of these tumors and their anatomical relations favored the diagnosis of cyst of the pancreas. True cysts of this character had been recorded, though they were rare. Lloyd had reported somewhat similar cases, and considered that they might be due to accumulations in a fold of peritonæum near the diaphragm, known as the bursa omentalis. Beautiful preparations were shown illustrating the wonderful power of absorption of the lymphatics of the diaphragm, and demonstrating the manner by which the tumors under consideration might have arisen.

Dr. Howard Kelly, of Baltimore, in opening the discussion on the previous papers, stated that changes in technique in abdominal surgery were necessarily of frequent occurrence in our struggles for the ideal. Drainage of the abdominal cavity after operation must be regarded as a confession of some error, though it might be unavoidable. He believed there were cases in which pelvic tumors were properly treated by abdominal incision, then incision and drainage of the vagina; but those were the cases in which it would be rash, and probably fatal to the patient, to entirely remove all diseased structures. He favored the free use of cathartics after abdominal operations, but not as a routine practice. If there was danger of sepsis, the purging should be begun before the operation. He was skeptical as to the importance of atmospheric influence concerning the outcome of an operation, if cleanliness had been the rule of practice. Hæmorrhage could be prevented if the pedicle was treated with sufficient care. Transfusion of a salt solution was indicated in cases in which the loss of blood or the shock had been considerable. He had saved life on several occasions by so doing.

Dr. A. G. Gerster, of New York, thought the statements of Dr. Price as to the objectionableness of pus in the pelvis would be conceded by everybody. He objected, however, to the strictures which had been made concerning those who believed that a conservative course in pelvic surgery was wise and correct, and quite agreed with Dr. Helly that some collections of

pus must be removed by drainage rather th n by extirpation of the abscess sac, if we wished to save the patient. The danger from aerial infection had been overestimated, in his judgment, and the personal equation was far more weighty iff determining the issue of a given case. The question of purgation should also be treated on a rational rather than a routine basis. It the intestines had become paretic, the time for the use of purgatives had passed.

Dr. Charles P. Noble, of Philadelphia, agreed with Dr. Price that there was still a useful field for drainage. In his opinion, its use did not signify bad work on the part of the gymacologist, but a bad case to work upon. In such conditions the drainage-tube would certainly be beneficial. The conditions of the case and the state of vitality of the patient would also be the guide as to the propriety of draining pelvic abscesses through the vagina. Of course, all the diseased structures should be removed, if they could be removed with reasonable safety. Hæmorrhage after abdominal operations was always a possibility, and occurred in most men's experience sooner or later, but it must always make one feel somewhat guilty if it did occur.

Dr. Price thought it was fair to assume that the motives of one who practiced abdominal surgery were honest until the contrary was proved, and one should not be too sensitive if his object was to bring the greatest possible relief to suffering women. The mortality in cases accompanied with suppuration increased above the age of forty and diminished under that age. Negro women endured severe abdominal operations better than white ones. We were much indebted to the negro race, for the early operations of Sims had all been upon black women. The risks in abdominal surgery were so great that one who had had little experience as a surgeon should not take them. The speaker's statements in regard to his motive in operating upon the poor had been misunderstood. His motive was as good as anybody's, and he had had the best results in very humble surroundings. Purgation should be practiced before the operation, not after it. Hæmorrhage after operation was usually an expression of bad surgery. The question of drainage was, as had been said, a question of cases, and drainage was almost always needed in dirty cases. If the operation was incomplete the patient would not be cured, and subsequent trouble must be expected. The trouble with the general surgeons was that they applied the principles of general surgery to special work. Opium was objectionable in the speaker's opinion, and be thought that one who could not do without it had much to

Three Cholecystotomies for Gallstones with Recovery, with Remarks on Operative Methods, based on Six Cases.— Dr. W. W. Seymour, of Troy, believed that gall-bladder surgery was at least as meritorious as the treatment of gallstones with Carlsbad water and oil. He narrated the histories of three successful cases in which he had operated. He was not in favor of the removal of the gall bladder if it could be avoided, or of the operation in two stages, which seemed to him to offer no advantages not possessed by the operation in one stage. His incision was an oblique one over the border of the liver, and the abdominal cavity was protected by gauze before incising the gall bladder. If a biliary fistula persisted, Murphy's button might be used in operating upon it. The morbid condition of biliary calculi was now quite generally recognized as a surgical affection, and it was not believed that they could be dissolved by any means yet tried.

Dr. H. MYNTER, of Buffalo, believed that the symptoms due to gallstones were now generally recognized, though there were some cases in which the diagnosis was obscure. A case was narrated in which a tumor of the abdomen was supposed to be a distended gall bladder, but was found, on abdominal section, to be a floating kidney.

Dr. SEYMOUR referred to the difficulty in distinguishing a gall bladder enlarged from calculi from one which was the seat of malignant disease, also from malignant disease of the liver. Riedel's statement that the tumor might disappear after the patient had been anæsthetized had been confirmed by the speaker. Bile in the urine, clay-colored stools, and epigastric pain were indications for operation, and an early attempt to relieve the trouble by surgical means was advocated.

Palpation of the Vermiform Appendix. - Dr. G. M. Ede-BOHLS, of New York, stated that it was quite as possible to palpate the normal or slightly enlarged appendix as to locate the Falloppian tubes and ovaries. His observations had been made almost entirely upon women, and during the past year he had had a number of opportunities of confirming his diagnosis by operation. Every woman who had been examined by him for pelvic disease had also been examined with reference to the condition of her appendix. The examination had been made with the patient in the dorsal posture, about a foot higher on the table than for the ordinary pelvic examination. The examiner stood on the right of the patient and with two or three fingers, the palmar surface downward, deep pressure was made along the line running from the umbilicus to the anterior superior spinous process of the ilium. The anterior structures of the abdomen being pressed against the posterior abdominal wall, the appendix would be detected between them. If the appendix was healthy it would not be sensitive, while the contrary would be the case if it was diseased. The appendix was usually found at McBurney's point, hence the value of that point in determining a diagnosis. The caput coli seldom obscured a diagnosis, and was seldom filled with fæcal matter, in his experience, as had been usually supposed.

Retroperitoneal Abscess from Duodenal Ulcer,-Dr. L. S. PILCHER, of Brooklyn, reported the case, and believed that diverticula of the duodenum resulting from such abscesses were very rare. He had found but one similar case recorded. The case which the speaker reported had occurred in a young man who had been sent to him to be operated upon for appendicitis. There was a fluctuating tumor in the left epigastric region which ruptured when its removal was attempted and discharged fluid of a puriform character. The tumor sac was a process projecting from the duodenum. Infective peritonitis set in and death resulted on the third day. The trouble had originated in a duodenal ulcer which had gradually enlarged and caused protrusion of the surrounding portions of the duodenum, resulting in the diverticulum or tumor which was found at the operation. The wet preparation was exhibited, also a colored drawing showing the relations of the tumor.

(To be concluded.)

# Book Notices.

The Cholera Epidemic of 1892 in the Russian Empire. With Notes upon Treatment and Methods of Disinfection in Cholera, and a Short Account of the Conference on Cholera held in St. Petersburg in December, 1892. By Frank Clewow, M. D. Edinburgh, Member of the Epidemiological Society of London, etc. London and New York: Longmans, Green, & Co., 1893. Pp. xii-123. [Price, \$1.75.]

The author, a resident of the English Hospital at Cronstadt, has taken advantage of his familiarity with the Russian

language to obtain directly from Russian sources the material that would afford a history of the epidemic of 1892. As this epidemic very nearly attained the magnitude of a pandemic, its history is of considerable interest to the student of medicine, because it was through Russia that the disease entered western Europe.

[N. Y. MED. JOTR.,

Cholera was introduced into Kaachka, Transcaspian Russia, from Meshed, Persia, about May 31, 1892, and the rapidity with which the disease spread through Russia was due to the number of new railways and to the increase of travel by rail.

A graphic picture is given of the method of living of the inhabitants of the southern Caucasus, and it is easy to see that the polluted air and polluted soil of their houses, as well as the polluted water that is drank, invite the introduction of cholera infection.

The familiar story of dirty towns and unsanitary reople is retold in the ravages of this epidemic. The railroads and the Volga steamers assisted in the rapid distribution of infected persons, and in every case the disease was manifestly the result, directly or indirectly, of some pre-existing case.

One of the most important facts insisted upon in this book is that the Russian Government fully realized the threatened danger and made efforts to prevent the disease passing the frontier and to minimize its effects when it had entered the country. The various orders of that Government are detailed, and the measures that were adopted seem to have been well considered.

In the chapter on treatment, the author states that the Russian physicians attached the greatest importance to the use of hot baths, usually of a temperature of 104° F., of twenty minutes' duration, and repeated from three to five times daily. The various modifications of Cantani's method of hypodermoelysis and enteroclysis employed in the different Russian hospitals are described, and reference is made to the various other therapeutic measures found useful.

The sterilization of the dejecta was accomplished by using a solution of carbolic and sulphuric acids, or by boiling the dejecta in special boilers, or by adding twenty per cent. of milk of lime. Wearing apparel was disinfected by means of boiling or steaming. Rooms were disinfected by sponging with a sublimate or carbolized solution. These measures were used in St. Petersburg and some of the larger cities.

A chapter is devoted to the conference on cholera held in December, 1892. This body condemned quarantine as unscientific, and on its recommendation ships from infected ports are to be detained only so long as the process of disinfection requires, sick passengers being removed to the hospital. In view of the investigations made at Hamburg, that showed that the evacuations of persons that had recovered from cholera contained Koch's bacilli in large numbers for some days after the cessation of the choleraic symptoms, it would seem that a decided source of infection has been left uncared for by such an authorization of the distribution of vessels' passengers.

The author refers to the decision of the authorities to hold the Nijni Novgorod Fair notwithstanding the epidemic. As there were 1,958 cases of cholera there during the summer, 891 of which were fatal, with no statistics of the number of persons that attended the fair, the number of visitors who died of cholera, or the number of visitors who acquired cholera while at the fair and carried the infection thence to healthy localities, it would seem that the author is not justified in characterizing as a strikingly mild visitation of the epidemic what seems to us to be a piece of blundering stupidity.

One can not but feel that this book emphasizes the preconceived idea that, if the Russian sanitary authorities carried out the American system of quarantine at the Caspian, Black Sea, and Volga ports, there would be less risk of cholera being introduced into the country, and of the welfare of Europe being jeopardized.

The author's work is a useful contribution to the history of cholera, and the maps and diagrams enhance its value to the profession.

Asiatic Cholera: its History, Pathology, and Modern Treatment. By A. J. Wall, M. D., Fellow of the Royal College of Surgeons of England, and of the Medical Staff of H. M. Indian Army (Retired List). London: H. K. Lewis, 1893. Pp. vi-194.

The author's experience as a surgeon in India is sufficient justification for his volume on a disease that has received much attention during the past two years. He briefly reviews the history of cholera, with special reference to the manner of its dissemination, and then presents the clinical histories of a number of cases, so as to portray the symptoms of the disease.

The chapter on the pathology of cholera presents the various changes produced in the tissues and fluids of the organism.

The various methods of treatment are referred to, but we are surprised that no reference is made to the stimulating effect of hypodermic injections of atropine, strychnine, or nitrogly-cerin.

The chapter on the ætiology of cholera is quite polemical in character, and the author seeks to refute the theory that the cholera spirillum of Koch is the cause of the disease. But other and able bacteriologists—Sternberg, Welch, Biggs, and Prudden in this country, for example—state that they have never found this spirillum in any disease except cholera, and Dr. Wall's position is certainly at variance with that of the majority of the medical profession.

The author's opinion regarding preventive measures seems to us very sensible. He says of quarantine: "We think it permissible to retain under observation the whole of the persons on board a vessel if there is reason to believe that any of them may be infected, till the risk arising from that infection is over." The chapter on the methods of arresting epidemics of infectious disease is the best in the volume.

The work will prove of interest to any one desiring information on cholera.

A Dictionary of Medical Science: containing a Full Explanation of the Various Subjects and Terms of Anatomy, Physiology, Medical Chemistry, Pharmacy, Pharmacology, Therapeutics, Medicine, Hygiene, Dietetics, Pathology, Bacteriology, Surgery, Ophthalmology, Otology, Laryngology, Dermatology, Gynæcology, Obstetrics, Pædiatrics, Medical Jurisprudence, Dentistry, etc. By Robley Dunglison, M. D., LL. D., late Professor of the Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia. Twenty-first Edition, thoroughly revised and greatly enlarged, with the Pronunciation, Accentuation, and Derivation of the Terms, by Righard J. Dunglison, A. M., M. D. Philadelphia: Lea Brothers & Co., 1893. Pp. xi-1181.

It is to be regretted that the editor of this work has made the attempt to compress into one volume such a multitude of headings. The result has been a very large number of terms with insufficient definitions. At the present time a dictionary of the words used in medicine to be of value must be either almost encyclopædic in size or so abridged as to contain only the terms more commonly used. To define intelligibly even the additions to the former editions of this dictionary would require almost as much space as there is in the entire volume. Insufficient definitions would seem to be worse than none.

For example, the angle of Cuvier is referred to facial angle, where the angle described is that of Camper, and, as a matter of fact, there are no fewer than seven angles described as facial, differing considerably from each other. Similar instances are found every few pages.

Some of the errors of the previous editions have been perpetuated, as in the use of abductor for adductor in the description of Hunter's canal, and the failure to give any idea as to what an echinococcus may be.

In citing these instances there is no intention to be hypercritical, but simply to show the extreme difficulty of the task the editor imposed upon himself.

The appearance of the book has been immensely improved by an increase in the size of the page, new type, and the omission of the large number of synonyms under each heading given in the former editions.

The Nurse's Dictionary of Medical Terms and Nursing Treatment. Compiled for the Use of Nurses, and containing Descriptions of the Principal Medical and Nursing Terms and Abbreviations, Instruments, Drugs, Diseases, Accidents, Treatments, Physiological Names, Operations, Foods, Appliances, etc., encountered in the Ward or Sick-room. By Honnor Morten. London: The Scientific Press, 1894. Pp. 139. [Price, 2s.]

This is a convenient pocket dictionary of terms that a nurse is likely to hear and perhaps to use. The definitions are sufficiently plain to be readily understood by one that does not possess a technical knowledge of medicine. We think that the value of the work would have been increased if the accent had been indicated.

Information for Nurses in Home and Hospital. By MARTIN W. CURRAN, Graduate of the Mills Training School, Bellevue Hospital, New York City. Illustrated. New York: J. H. Vail & Co. Pp. xvi-333. [Price, \$1.50.]

The author of this volume has collected a considerable amount of information likely to be useful to a trained nurse. It has been his desire to make the volume essentially practical, and its scope is much less extensive than that of most of the manuals on nursing. In his desire to be brief he has occasionally sacrificed clearness, and the proof-reader is often seriously at fault.

Operative Surgery. By TH. KOCHER, M.D., Professor at the University and Director of the Surgical Clinic at the Berne University. With One Hundred and Sixty-three Illustrations. New York: William Wood & Co., 1894. Pp. ix-279.

This is a condensed manual of operative surgery. The author describes in a concise and clear manner most of the ordinary surgical operations. The cuts are principally in outline, but easily understood and very accurate. As a guide to one who does little surgery it will be very useful, but to the general operator who seeks a reference book to learn which one of the various methods will best suit a perplexing case, the book will be of no avail. The author has laid down his own choice as the one method of doing everything, and does not trouble himself to describe others. Of course his operations are generally the accepted ones, and may be safely followed, but then we should like to know the others in cases of emergency. Beyond this there is little to be said in criticism of this book. The general make-up is well arranged and in good taste. To the general practitioner, whose time is limited, it will be a most valuable aid.

Chirurgie des roies urinaires. Études cliniques par le Dr. E.
Loumeau, Professeur libre de clinique des maladies des
voies urinaires, etc. 2me édition. Revue, augmentée et
accompagnée de cinq planches hors texte noires et chromolithographiées. Bordeaux: Feret & fils, 1894. Pp. 300.

This volume, as its title indicates, includes a collection of histories of cases relating to the surgery of the urinary passages. The author states that all these histories have been published in various medical journals since 1891. Many of the conditions he reports are rare, all are interesting, and to each he appends commentaries suggested by the facts relating to the case. The volume is a useful contribution to the literature of genito urinary surgery.

The Physiology of Death from Traumatic Fever. A Study in Abdominal Surgery. By John D. Malcolm, M. B., C. M., Fellow of the Royal College of Surgeons of Edinburgh, etc. London: J. & A. Churchill, 1893. Pp. iv-129. [Price, 3s. 6d.]

This brochure, abstracts of which have appeared in the Lancet and in the Transactions of the Medical Society of London, is a purely theoretical argument upon the physiological conditions in death from traumatic fever or shock. The author seeks to prove that the blood-vessels are contracted and not dilated or relaxed in this condition, and that this contraction is the cause of destruction of tissues and loss of the vital principles in the blood. While the argument is deep, we see no evidence of any very scientific experiments, and we do not appreciate why it should ever have been published as a book.

Three Introductory Lectures on the Science of Thought. By F. Max Müller. With an Appendix which contains a Correspondence on Thought without Words, between F. Max Müller and Francis Galtou, the Duke of Argyll, George J. Romanes, and Others. Chicago: T e Open Court Publishing Company, 1893. Pp. vi-3 to 95. [Price, 25 cents.] [The Religion of Science Library.]

THESE lectures, here reproduced, were delivered in 1887 and have since been used as the first portion of the author's well-known work on *The Science of Thought*. This form will probably introduce them to a larger audience.

The Physician's Wife and the Things that Pertain to her Life By Ellen M. Firebaugh. Illustrated with Forty-four Photoengravings of Sketches from Life. Philadelphia: The F. A. Davis Co., 1894. Pp. xi-186.

To a woman full of sentiment it is hard to be matrimonially allied to a doctor. His time is occupied largely in the care of his patients, and in his leisure hours his mind is full of theories and devices for the relief of human ills. It has been said "the physician's wife does not know what marriage is," and we believe there is much truth in the saying. She must be fertile in her own resources for personal amusement, as she can never depend upon her husband for any social duties. Owing to the imperative demands upon them, doctors are excused from social obligations, and, being excused, they get into the habit of making no effort to fulfill them. Society meetings and scientific gatherings take them from home when patients do not, and, as a rule, the physician's own home circle sees less of him than any other. The wife is the sufferer in all these things, for she can not take part in his work. She is provided with a home and must make the most of it for herself. To one acquainted with these facts the complaints of the author of this little book are so trivial as to be amusing. For a seriously intended book it is the most amusing we ever read. .

Suicide and Insanity: a Physiological and Sociological Study. By S. A. K. Strahan, M. D., Barrister-at-Law, Member of the Honorable Society of the Middle Temple, etc. London: Swan, Sonnenschein, & Co., 1893. [Price, \$1.75.]

The author states that the prevalence of suicide in England during the summer of 1893 brought the topic of self-destruction prominently before the public; but we doubt if there was any greater increase in suicides in England than elsewhere in the world. In this volume an attempt is made to trace suicide to its source, which the author believes to be cultivation; and to show how large a percentage of what is really avoidable is deliberately propagated by the marrying of the insane, the epileptic, and the criminal.

The first chapter in the volume reviews the history of suicide in early times, and it is noted that Mohammedanism and Zoroastrianism are the only religions that have prohibited suicide. There is nothing in the Old Testament that prohibits it, and the author refers to the several instances wherein it is mentioned without condemnation. If "Thou shalt not kill" refers to suicide, it is only by "construction and implication." Did the author, in his Biblical references, intentionally ignore the suicide of Judas Iscariot?

Self-destroyers are divided into two classes, rational and irrational. In the first the reason of the individual is called upon to decide between death and a continuance of life, and chooses the former. In the second the individual is impelled to destroy his life by an innate craving or instinct, by an uncontrollable impulse, or by the unhealthy reasoning of a disordered intellect.

Rational suicides include religious devotees, those who die to follow friends, those who die to gain notoriety, and those who die that others may gain. The latter class does not seem to us germane to the subject, for a person endeavoring to save another's life is not indulging in a train of reasoning as to whether his own life will or will not be sacrificed; such a question is fundamentally alien to his acts. for the fact that there is a chance that he may save another's life includes the possibility of saving his own. To place Christ in such a class seems extraordinarily erroneous from any extrinsic or intrinsic theological standpoint. This class also includes those who die to escape evil, such as physical suffering, slavery and persecution, punishment, disgrace or dishonor, and poverty. In general, this class the author does not believe to be true suicides, because he believes with the old Greek philosophers: "Live so long as it is agreeable to you; go if you do not wish to suffer; but if you deliberately choose to stay do not complain." Voluntary death is merely one of the eliminative processes of natural selection.

Irrational he considers true suicide. This includes three groups: First, that in which there is mental aberration. Second, that in which the act depends upon an irresistible impulse, and in which there is no mental aberration. Third, that in which a certain predisposition makes it possible for a slight shock, trial, or irritation to awaken the unnatural impulse. Each of these groups is separately considered.

The influence of race, that of climate and season, that of religion, and that of sex and age are discussed in regard to the prevalence of suicide.

The author states that the increase of suicide is largely due to hereditary transmission. We do not believe that this is, as he states, absolutely certain, and not enough is known to prove the soundness of his assertion. On the contrary, the difficulty of proving by statistics the part played by heredity is insurmountable, as he acknowledges. On him, as the assertor, rests the onus probandi. We do believe that excessive cultivation of those whom Nature never intended to fill other than an insig-

nificant  $r\delta le$ , but whom the chance of the day has surrounded with wealth and its corrupting influences, sooner or later produces degenerative changes that are but expressions of her efforts to eliminate the social funges. We also believe that the influence of environment in causing mental instability produces a second class that is prone to suicide.

The chapter on suicide and the law is very interesting, and we wish it could be impressed upon the legislators of this State, who are asked to revoke the absurd laws that stultify our intelligence. As the author says, pronouncing suicide a crime has never stayed the hand of a single individual bent on self-destruction. It would be best to no longer consider suicide a crime, and to ignore attempts thereat. The author suggests that better than prohibitory laws would be the enactment that all attempts at suicide, whether successful or not, should be considered in themselves conclusive evidence of dangerous insanity. In the last analysis he agrees with Donne that "self-homicide is not so naturally sin that it may never be otherwise."

The book is a most interesting contribution to the literature of a subject that is of increasing interest to the alienist and the psychologist.

#### BOOKS, ETC., RECEIVED.

Politzer's Text-book of the Diseases of the Ear and Adjacent Organs. For Students and Practitioners. Translated by Oscar Dodd, M. D., Assistant Surgeon at the Illinois Charitable Eye and Ear Infirmary, etc. Edited by Sir William Dalby, F. R. C. S., M. B. Cantab., Consulting Aural Surgeon to St. George's Hospital. With Three Hundred and Thirty Original Illustrations. Philadelphia: Lea Brothers & Co., 1894. Pp. xi-739. [Price, \$5.50.]

Pain, Pleasure, and Æsthetics. An Essay concerning the Psychology of Pain and Pleasure, with Special Reference to Æsthetics. By Henry Rutgers Marshall, M. A. London and New York: Macmillan & Co., 1894. Pp. xxi-364. [Price,

Tumors Innocent and Malignant. Their Clinical Features and Appropriate Treatment. By J. Bland Sutton, Assistant Surgeon to the Middlesex Hospital, London. With Two Hundred and Fifty Engravings and Nine Plates. Philadelphia: Lea Brothers & Co., 1893. Pp. xvi-511. [Price, \$4.50.]

Syphilis in the Innocent (Syphilis Insontium). Clinically and Historically Considered, with a Plan for the Legal Control of the Disease. By L. Duncan Bulkley, A. M., M. D., Physician to the New York Skin and Cancer Hospital, etc., New York: Bailey & Fairchild, 1894. Pp. xvi-398. [Price, \$3.50.]

A Manual of Minor Surgery and Bandaging. For the Use of House Surgeons, Dressers, and Junior Practitioners. By Christopher Heath, F. R. C. S., Surgeon to the University College Hospital, etc., London. Tenth Edition. Philadelphia: P. Blakiston, Son, & Co., 1894. Pp. xvi-389. [Price, \$2.]

The Year-book of Treatment for 1894. A Critical Review for Practitioners of Medicine and Surgery. Philadelphia: Lea Brothers & Co., 1894. Pp. viii-492.

Clinical Lectures on Pædiatrics, delivered in the Vanderbilt Clinic during the Session of 1892-1898. By A. Jacobi, M. D., Clinical Professor of the Diseases of Children in the College of Physicians and Surgeons of New York, etc. (Stenographic Reports.) New York: Bailey & Fairchild, 1893. Pp. 192. [Reprinted from the Archives of Pædiatrics.]

On the Influence of Various Diets upon the Composition of the Urine, and the General Condition of Patients suffering from Chronic Bright's Disease. By W. Hale White, M. D., London. [Reprinted from the Medico-chirurgical Transactions.] The Treatment and Prophylaxis in Insanity. By John Punton, M. D., Kansas City. [Reprinted from the Alienist and Neurologist.]

The Modern Crank and Mental Responsibility. By John Punton, M. D. [Reprinted from the *Tri-State Medical Journal*.]

Review of Recent Advances in our Knowledge of the Anatomy and Physiology of the Nervous System. By John Punton, M. D. [Reprinted from the Kansas City Medical Index.]

Sarcoma of the Kidney; its Operative Treatment. By Robert Abbe, M.D. [Reprinted from the Annals of Surgery]

Tait's Perineal Flap Operation. By F. Byron Robinson, M.D. [Reprinted from the Chicago Medical Recorder.]

Total Extirpation of the Uterus. Cases illustrating Various Indications for and Different Methods of performing the Operation. By George M. Edebohls, M. D. [Reprinted from the Transactions of the New York Obstetrical Society.]

The Technique of Total Extirpation of the Fibromatous Uterus. By George M. Edebohls, M. D. [Reprinted from the American Journal of Obstetrics.]

The Operative Treatment of Complete Prolapsus Uteri et Vaginæ. By George M. Edebohls, M. D. [Reprinted from the Journal of Obstetrics.]

Critique of Microscopic Examination of Specimens removed in Thirty-two Consecutive Laparotomies. By F. Byron Robinson, M. D. [Reprinted from the Journal of the American Medical Association.]

Surgical Notes from the Babies' Wards, Post-graduate Hospital, New York City. Robert Abbe, M. D., Attending Surgeon. Reported by Dr. Theodore Dunham. Report 1. [Reprinted from the *Post-graduate*.]

Operation for the Correction of Deformity of the Wrist caused by Shortening of the Radius after Fracture. By E. S. Goodhue, M. D., Cal. [Reprinted from the Medical Record.]

Tetanus complicating Vaccinia. By S. W. S. Toms, M. D., L. I. [Reprinted from the *Medical News*.]

Pigmentation of the Whole Surface of the Body, occurring Suddenly during the Treatment of a Case of Psoriasis. Warty Growths upon the Palms and Soles following the Internal Use of Arsenic. By Albert E. Carrier, M. D., Detroit. [Reprinted from the Medical News.]

Parasites dans le cancer. Par le Dr. Nepveu, Marseilles. [Extrait des Archives de médecine expérimentale.]

Hospitals, Dispensaries, and Nursing. Papers and Discussions in the International Congress of Charities, Correction, and Philanthropy, Section III, Chicago, June 12 to 17,18 93. Edited by John S. Billings, M. D., and Henry M. Hurd, M. D. Baltimore: Johns Hopkins Press, 1894. Pp. xiv-718.

## New Inbentions, etc.

A NEW ALCOHOL LAMP.

BY WILLIAM M. LESZYNSKY, M. D.

This lamp has been specially constructed with a view to its utilization in the application of cupping glasses. It is made of nickel-plated brass, is five inches long and an inch in diameter, and is provided with a screw-cap and washer for preventing

leakage or evaporation. It is hoped that it will materially simplify the process of applying dry cups, thus dispensing with the ancient and dangerous methods still in vogue, such as the use of matches, pouring alcohol into each glass and igniting it, lighting small pieces of paper or absorbent cotton previously saturated with alcohol, and even the safe but frequently inconvenient method by means of alcohol and a sponge probang. All these methods, being for the purpose of producing a vacuum in the glass, will be readily and rapidly subserved by this specially adapted lamp, which may be handled like a torch. On account of its size, shape, and simplicity in construction it may be safely carried in the pocket or in any instrument bag, and used whenever a spirit lamp is required. It is made by E. B. Meyrowitz, of New York.

## Miscellany.

Trephining among the Ancient Peruvians.—The January-February number of the Bulletin of the Johns Hopkins Hospital contains a paper presented to the Historical Club of the hospital on December 11th by Mr. W J McGee, of the Bureau of American Ethnology, entitled Primitive Trephining, illustrated by the Muñiz Peruvian Collection. This collection, it appears, was made by Dr. Muñiz, the surgeon general of the Peruvian army, and includes nineteen specimens of trephined portions of skulls.

"About half are of interest chiefly," says Mr. McGee, "as indicating the manner in which the operation was performed. Three types of operation are exemplified. In the first type four linear incisions were made in the cranium in parallel pairs intersecting each other at right angles so as to form a rectangular button; the incisions being narrow, v-shaped in cross section, and gradually increasing in depth from ends to center, thus indicating that the instrument was a pointed bit of stone or arrowhead held vertically and operated by reciprocal motion. This suggestion gains strength from the fact that American Indians are known to have produced incisions in bone in this fashion. This type of operation is rude and the resulting traumatism is jagged, each incision extending perhaps half an inch beyond the button at each extremity. There is no indication of the purpose of the operation of this type in any case, and nothing to suggest that if the operation was ante-mortem the individual survived. Aberrant examples of this type exhibit three or more parallel incisions, one example consisting of three approximately parallel incisions in each of the two rectangular sets forming a quadruplicate button or four coincident rectangles of which one remains, the other three being completely removed; and in another example the incisions of the rectangular system are still more numerous, and there are some oblique incisions, nearly four square inches of bone being removed and no fewer than twenty distinct incisions showing about the margin of the aperture.

"In the second type of operation the incision was evidently made also by a rudely pointed instrument, probably of stone, held vertically and moved reciprocally; but as the cutting reached and penetrated the inner table, the locus of incision was moved forward and at the same time the direction of the sawing was changed so as to produce a rudely curved cut and, when two such incisions were made, an irregularly elliptical button. Some examples indicate that this type of operation was completed by scraping or grinding away the jagged surfaces left by the incision.

"The third type of operation was performed largely or wholly by scraping in such manner as to remove the outer table and diploë and reduce the inner table to a feather edge. Some of the examples suggest that the scraping, which may easily have been effected with stone instruments and gives no indications of the use of metal, represents the final part of an operation begun by the curved incision.

"Several specimens show by spicules of reparative growth and by the partial absorption of the outer table and diploë that the patient survived the operation, and hence that the trephining was ante-mortem. One individual appears to have long survived an operation forming a rudely circular aperture about three quarters of an inch in diameter in the posterior portion of the cranium, and probably also for a short time a similar operation involving the metopic suture (which in this case is distinctly preserved). Another individual long survived two operations, probably of the second type, giving apertures nearly an inch in diameter, but apparently died about the time of the completion of a third trephining involving the coronal and sagittal sutures. A third individual long survived, as indicated by the reparative spicules and the complete absorption of outer table and diploë, an operation by scraping giving a rudely circular aperture about an inch in diameter. In none of these cases is the purpose of the operation evident." . . .

"Several examples are exceptionally noteworthy in that they prove the operations to have been surgical. In the first example the cranium shows a depressed fracture of the left temple, such as might have been produced by impact of a slingstone or blow from a spiked club, which are known to have been the weapons used among the ancient Peruvians. An operation essentially of the first type was begun, but only three incomplete incisions were made and the button was not removed when the work was discontinued, probably by reason of the death of the patient. The second example shows marks of a similar fracture in the posterior portion of the left parietal; in this case four incisions of the first type (although one is oblique) were made, and the operation was carried far enough to remove the button, but not the jagged edges resulting from fracture and operation, this individual also apparently dying in the hands of the operator. A third specimen displays a compound fracture involving the left temporal suture; and in this case an operation was performed by scraping, producing an elliptical aperture about five eighths by three quarters of an inch; and there is in addition a simple vertical incision such as those produced in the first type of operation, which apparently represents the first stage of supplementary treatment. This individual also apparently died before the final operation was completed. Another example exhibits a linear fracture fully six inches long, extending from near the center of the occipital across the lower portion of the right parietal and across the temporal, disappearing under the zygomatic arch. The treatment in this case consisted of scraping at several points along the fracture, including a scraped trephining, yielding an aperture of about three eighths of an inch in the occipital bone not

far from the termination of the fracture. This operation would appear to have been completed to the satisfaction of the surgeon. Then, as indicated by the condition of the specimen (a mummy in which a considerable part of the scalp is preserved), the scalp was laid open over the occiput and two incisions representing an operation of the first type, together with a minor vertical cut, were partially completed before treatment was finally abandoned, apparently by reason of death. Thus, while it can hardly be said that these four examples demonstrate the ante-mortem date of the operation, since it is just conceivable that they might represent post-mortem exploration, they nevertheless prove that, if ante-mortem, the operation was surgical; and the ante-mortem date of the operation in some cases is proved by examples already noted.

"One of the specimens is of exceptional interest in several ways. The skull is small and thin; the ankylosis of the sutures is so far progressed as to indicate an age of twenty-five or perhaps thirty years; while the development of the teeth indicates an age not exceeding twelve years. In this case the aperture, which is on the right side, is of remarkable size, extending from the frontal within three quarters of an inch of the orbital cavity across the coronal suture nearly to the center of the parietal, its length being fully four inches and the width averaging an inch. The specimen is of interest also in that it was the only one in which a plate is known to have been used, a silver plate having been found in place over the aperture in the mummy case. The presence of the plate, its seat in the skull showing long wear, and the absorption and reparative growth, all indicate that the operation was survived. No wound appears in the vicinity of the trephining, but there is a traumatic depression on the left side of the frontal an inch and a half above the orbital cavity and about the same distance from the center line, apparently due to a blow, such as produced the depressed fractures in other examples, suffered in early life when the bone was soft. Now, while the operation can not directly be traced to this traumatism, it is suggested that this wound produced the abnormal, perhaps epileptic, condition which is indicated by other characters of the skull; and that the enormous trephining represents successive operations designed to relieve this condition. If these inferences be true, it will follow that the operation in this case was not only surgical, but parallel with the non-traumatic trephining of modern practice, thus indicating a considerable advance in medical knowledge and surgical skill."

Painting with Guaiacol and its Absorption by the Skin .- In the Province médicale for February 17th there is an article on this subject contributed by M. Guinard and M. Stourbe, in which it is shown that guaiacol is found in the urine of persons who have been painted with this medicament. It is known that guaiacol is found in the urine of those who have inhaled and absorbed its vapors through the lungs, but it has also been seen that the proportion which penetrates in this way is not very large. The author relates the case of a young man on whom he experimented twice. The first time the thigh was painted with thirty grains of guaiacol and then covered; the temperature simply fluctuated between 98.6° and 98.5°, and a considerable proportion of guaiacol was found in the urine. The second experiment was made in the morning after the patient had spent the night in dancing, and probably drinking. He was tired, and experienced the general discomforts consequent upon such dissipation; there was heaviness of the head, and he was particularly sensitive to cold. An excessive indulgence in alcoholic drinks and insufficient rest had given rise to these nervous conditions, which slightly modified the results of the experiment. His temperature was about 97.5°, and after the application of fifteen

grains of guaiacol on the left thigh, under the conditions described above, the temperature presented successive changes, In addition to the fall of temperature, the patient felt a sensation of smarting at first, which persisted for about fifteen minutes, and also at the end of the experiment a sensation of heat all through the left leg, with excessive sweating in the same part. Finally, after this experiment, which lasted two hours, a larger proportion of guaiacol was found in the urine.

M. Guinard also relates the cases of five patients who were subjected to applications of guaiacol with or without the envelopment of the parts painted, and draws the following conclusions from these experiments: That guaiacol can penetrate through the epidermis; that this penetration appears to be the result of an absorption of the vapor; that the envelopment of the painted regions, thus keeping the vapor in contact with the skin, increases the proportion of guaiacol in the urine, and exaggerates the sensation of heat which it produces on the extremities and on the hand; finally, that probably in this explanation will be found the cause of the differences existing in the antipyretic effects, according as the painted regions are covered or allowed to remain uncovered.

Compression of the Phrenic Nerve as a Therapeutic Measure .- The Journal des praticiens for February 10th contains a letter from its Marseilles correspondent in which its readers are reminded that seven or eight years ago Dr. Bidon conceived the idea of assuaging hysterical spasm of the glottis by exerting digital compression on the phrenic nerve between the heads of the sterno-cleido-mastoid muscle. After that Leloir advised this procedure as a means of checking hiccough. Now M. Bidon suggests it afresh as a remedy for spasm of the glottis in persons suffering with tabes. The following is a summary of a case thus treated: The patient, a man thirty-eight years old, complained of fulminant pains, incontinence of urine, and muscular weakness, and showed Westphall's and the Argyll-Robertson symptoms. Every ten minutes he was attacked with vertigo, weakness in the legs, a half-fainting condition, and a sensation of suffocation. M. Bidon compressed both phrenic nerves with the fingers. The spasm ceased and the difficulty in breathing disappeared, but only provisionally and for a few minutes after the compression. The use of the measure was persevered in, and in eight days the cure was lasting. How, asks the correspondent, is this phenomenon to be interpreted? By a paralyzing action on the diaphragm, or by an inhibitory action on the nervous centers in such manner as to suspend spasm of the constrictor muscles of the glottis, or by direct compression of the laryngeal muscles? He does not attempt to answer the question, but he remarks that the fact is memorable from a clinical point of view.

Expression of the Placenta.—In the Medical Report for 1893 of the Society of the Lying-in Hospital of the City of New York (Midwifery Dispensary) Dr. J. W. Markoe describes a modification of the Credé method of dealing with the placenta. He says:

"It is obvious, from the literature upon this subject, that the relation of the axis of the vagina to that of the uterus has been ignored. A few suggest obliterating the flexions in the uterine canal, but none seem to have recognized that the axis of the parturient uterus is nearly at right angles to that of the vagina—a point which, to the writer, seems the cause of all the difficulties which they have encountered. It is not my intention to compare the merits of the different methods, but to suggest a modification applicable to all the methods of expression, which has proved most satisfactory to me in practice and is mechanically correct.

"In some cases, especially in primiparæ, the uterus contracts

firmly around the contained placenta and membranes, remaining in this condition until the expulsion of the secundines, while in other cases the uterus rhythmically contracts and relaxes each time, becoming more and more firm; while still in other cases the uterine muscles seem to have expended all their energy in the expulsion of the child, and we have a flaccid organ which will be accompanied by hæmorrhage, if the thrombi in the uterine sinuses have not already formed. In practicing Credé's method of removing the placenta, no fixed time need be set, except that as soon as the relaxation of the uterine fibers has so far disappeared that the uterus remains under the hand as a firm body, then expression may take place at any moment: To accomplish this successfully and with the least discomfort to the patient, three things are necessary: First, the patient must relax the abdominal walls as much as possible. Second, the uterus must be firmly contracted. Third, the axis of the uterine canal must be made to conform to the axis of the vagina. If these three essentials be present and the placenta is not absolutely adherent to the uterine wall, the expulsion can be accomplished with two fingers and but little effort.

"As in all obstetric operations, before proceeding the bladder should be emptied, especially in this manipulation, as a distended bladder forces the uterus upward and prevents the easy handling of the uterus. Then, standing at the side of the patient, her knees being drawn up, with one hand grasp the fundus through the abdominal wall and ascertain the precise direction of the uterine canal. This being known, all that is necessary to bring the axis of the uterus in line with that of the vagina is to gently press the fundus backward toward the promontory of the sacrum, thus throwing the cervical portion of the uterus forward and bringing the uterine axis in line with that of the vagina. The obliteration of this angle reduces the resistance to the minimum, thus diminishing the force requisite to accomplish the expression. The next step is to direct the pressure upon the fundus in the direction of the vagina, care being taken that it be kept well back, in order that the angle may not recur. If this is properly carried out, the placenta is received in the other hand at the vulva."

The Prevention of Cracked Nipples.—The Lancet's Paris correspondent says: "The direct relation of mammary abscess occurring during the period of suckling and excoriations of the nipple is now fully admitted. Many mothers object to suckling their infants on account of the dread of this complication. Artificial feeding with its frequent failures is then resorted to, and the child suffers. Antiseptic washing of the nipples has greatly diminished the frequency of abscess of the breast, but cracked nipples continue to be of common occurrence. For the last ten years Professor Pinard has been in the habit of advising nurses as a matter of routine to keep the nipples covered with a compress saturated with a solution of boric acid. This precaution has had the effect of markedly diminishing the frequency of lymphangeitis, but instances of an increase of temperature in young mothers due to microbian infection of the nipples are still numerous. M. Lepage strongly recommends that the nipples should be regularly washed with the following solution: Red iodide of mercury, 10 to 20 centigrammes; spirit of wine, 50 grammes; glycerin, 500 grammes; distilled water, 450 grammes. If after using this for a few days the ulceration disappears, substitute a solution of boric acid. Any crack that may develop is covered with tarlatan moistened with the mercuric solution. The following figures appear to confirm M. Lepage's good opinion of the comparative value of his method. In 331 cases of lying-in women whose breasts were treated by the Pinard method there was an increase of temperature in 67, the corresponding figures in M. Lepage's cases

being 23 out of 440. Moreover, the healing of the cracks is said to be expedited and the pain greatly diminished by the mercurial treatment."

The Respiratory Complications of Chicken-pox.—In the Presse médicale for February 17th we find a brief summary of a Paris thesis, by Dr. L. Boucheron, in which the author draws attention to accidents affecting the larynx, the bronchi, and the lungs which sometimes supervene in the course of chickenpox, and impair the renown for benignity enjoyed by this disease. Along with broncho-pneumonia and pleurisy by secondary infection for which chicken-pox prepares the way, it must be admitted that there is a primary disposition on the part of the eruption to attack the mucous membrane of the air-passages. Certain cases show that not only stomatitis but laryngitis, broncho-pneumonia, and perhaps even pleurisy may be of a varicellous nature. The author relates an interesting case of his own-that of a little girl who, already weakened by a preceding attack of whooping-cough, was seized with chicken-pox, characterized by successive eruptions, and died about the twentieth day in consequence of laryngeal spasm. At the autopsy nothing was found to explain the occurrence of the spasm except vesico-pustules, similar to those of the cutaneous eruption, occupying the laryngeal mucous membrane at the level of the arytænoid region and the posterior portion of the vocal cords. This is thought to be the first case of the kind re-

The New York Academy of Medicine.—The special order for the meeting of Thursday evening, the 15th inst., was a paper on Greek as the International Language of Physicians and Scholars in General, by Dr. Achilles Rose.

At the next meeting of the Section in Ophthalmology and Otology, on Monday evening, the 19th inst., Dr. Charles H. May will show a simple combination chart of test-type, also a modified cilia forceps; Dr. Justin B. Barnes will show an adaptation of the Maddox cylinder to the phorometer; and Dr. W. E. Lambert and Dr. W. B. Marple will demonstrate devices for facilitating retinoscopy.

At the next meeting of the Section in General Medicine, on Tuesday evening, the 20th inst., Dr. Adolph Zeh will read a paper on the Dietetic and Therapeutic Management of Typhoid Fever, and Dr. A. R. Bellamy will show a new apparatus for administering the Brand bath.

At the next meeting of the Section in Obstetrics and Gynæcology, on Thursday evening, the 29th inst., Dr. Paul F. Mundé will read a paper on Abscess of the Ovary, and Dr. S. Marx one entitled Further Contributions to the Study of Occipitoposterior Positions.

A Fatal Case of Displacement of the Spleen,-At a recent meeting of the Paris Société de chirurgie, a report of which appears in the February number of the Revue de chirurgie, M. Heurtaux, of Nantes, related the case of a girl, seventeen years old, who had an abdominal tumor accompanied by symptoms comparable to those observed in cases of torsion of the pedicle of an ovarian cyst. M. Heurtaux performed median laparotomy and encountered a tumor which he recognized as the spleen, very much augmented in size, and having undergone a movement of twisting on its pedicle. The capsule was thickened and adherent to the peritonæum and to the neighboring organs. The spleen was removed. The patient died on the third day after the operation, and an autopsy failed to disclose the cause of death, so it was thought that it must have been the shock of the operation. The displacement of the spleen seemed to have been due to the excessive length of its

# THE ACADEMY OF MEDICINE IN RELATION TO PUBLIC HEALTH.

ADDRESS OF THE RETIRING CHAIRMAN OF THE SECTION IN PUBLIC HEALTH, ETC.

Delivered December 19, 1892.

By S. T. ARMSTRONG, M. D., Ph. D.

Before transferring the duties and responsibilities of the chairmanship of the Section in Public Health, Legal Medicine, and Medical and Vital Statistics to my successor, whom you are to elect this evening, it seems appropriate to review the history of the Academy of Medicine in its relation to questions pertaining to public health, for the experience and action of the past serve as guides and precedents for the future, and the complexity of living in large cities affords problems for the sanitarian that should engage the attention and action of this section.

The first anniversary discourse of the academy was delivered on November 10, 1847, by Dr. John W. Francis, who referred to the fact that hygiene, state or political medicine, had long constituted an important branch of medical education on the European continent, and he said that if the members of the academy were the followers of Hippocrates hygiene would receive more attention at home. His words fell on responsive ears, and that the academy then considered it to pertain to its functions to take an active part in questions affecting public health may be judged from the appointment in 1848 of a committee to report upon the comparative value of milk formed from the slop of distilleries as a food. On March 1, 1848, Dr. Augustus K. Gardner, the chairman, presented the report of "the committee of eleven that were to examine into the effects, proximate and remote, upon the general health of the city caused by the numerous distilleries, gas works, slaughter houses, milk establishments, lead manufactories, tanneries, and all other manufactories and establishments that are or may be styled nuisances, from their deleterious effects upon the health; and particularly to report the effect upon the human economy of milk taken from kine tuberculously or otherwise diseased from improper food or confinement in these milk establishments." This report particularly condemned the use of milk from cows that were stall-fed on distillery swill, and it recommended that the public authorities be informed of this conclusion so that they might take such action as they saw fit.

It is not possible to learn from any accessible records what further work in sanitation was inaugurated by the academy, but that there were some fellows interested in hygiene is attested by article six of the third section of the constitution of 1852, that provided for the creation of a number of scientific committees, the seventh of which was that in public health and legal medicine. These committees were originated for independent work, the academy only retaining the right to regulate their membership.

In 1854 the standing committee on public health and

legal medicine was composed of John H. Griscom, chairman; John R. Van Kleek, secretary; Benjamin Drake, W. N. Blakeman, John Shanks, Joseph M. Smith, Samuel A. Purdy, A. L. White, James Stewart, and James M. Minor, A report was received from it regarding solidified milk, that was commended as a valuable addition to the resources of the traveler, as a suitable food for infants, and as a desirable article for the diet of invalids.

Apparently some of the fellows thought that a body composed exclusively of physicians was too restricted in its membership to exercise the greatest influence in promoting public health, for Dr. J. H. Griscom, in the anniversary discourse in 1854, after referring to many questions in public hygiene, advised that there should be organized a "hygiological society, having as objects of inquiry and action the entire field of the preservation of public and private health in all its varied and multitudinous relations; this society to be composed of laymen and physicians." But sufficient interest in this proposal could not be aroused at that time.

The academy seemed to find the title "Standing Committee" cumbersome, and in 1855 the constitution provided that these committees should be known as "Sections." Still, in December, 1856, under the old title of Committee on Public Health, a report was presented on alga chocolate and biscuits, in which these articles were said to be wholesome food. In that year Dr. J. H. Griscom was the chairman and Dr. J. G. Adams the secretary of the section.

It is unfortunate that no permanent records were kept of the work of the section in these early years of the academy, as Dr. J. P. Batchelder testified in his inaugural address in 1858 to the activity of the sections, each having from one to two meetings a month.

On June 7, 1858, a communication was sent to the academy from the board of health requesting that the academy lay before the board such facts and evidence as it had in relation to the milk furnished to the citizens of New York. A special committee was appointed, consisting of John Watson, J. P. Batchelder, B. Fordyce Barker, A. N. Gunn, and S. Rotton Percy, that made a report condemning the practice of housing milch cows in cities and of feeding the animals with distillery swill, condemning the use of the flesh or the milk from these animals for food, and recommending that milk venders be licensed and that the source of their milk supply be ascertained.

Perhaps at that time there was some uncertainty regarding the right of the academy to engage in work of this public character, for on the 20th of October, 1858, an amended constitution was adopted, in which the fourth object of the academy was specified to be the promotion of public health. Why those that framed our present constitution omitted this laudable and proper aim can not be here told. Certainly no body of medical men derogates from its proper functions when in any way attempting to promote public health. It would seem that the academy had weakened rather than strengthened its position and influence in the community by such an omission.

In 1862 the title of the section was amended to its

present designation—the Section in Public Health, Legal Medicine, and Medical and Vital Statistics.

On September 16, 1863, Dr. John II. Griscom, whose interest in sanitary matters did not wane, presented to the academy, on behalf of the section, a report on the Ridgewood disinfecting powder, narrating a number of experiments that were made to determine the value of that preparation, which was commended as a suitable article for the purposes intended.

On May 16, 1866, Dr. Stephen Smith presented a report from the section on the measures of prevention and relief to be adopted during the prevalence of epidemic cholera; on May 30th Dr. E. R. Squibb presented a report from the section on disinfectants; and on June 6th Dr. Elisha Harris presented a report on sanitary police measures applied to the prevention and control of epidemic cholera. These subjects were carefully considered and resolutions were adopted by the academy regarding the methods and manner of handling cholera.

In the address of the retiring president, Dr. James Anderson, delivered January 16, 1867, he said: "It is with pleasure that I can refer your minds to the gratifying results of the disinterested efforts of the academy in the primary movements for the organization by the Legislature of the Metropolitan Board of Health—the child of the academy, brought forth by the continued efforts of the academy and its fellows during several years of protracted labor, with final triumph, by the aid of the Citizens' Association, effectually seconded by the prevailing fears of the approaching pestilence knocking at the doors of the city."

In 1877 and 1879 the only sections that were reported as doing work were those in surgery, in theory and practice of medicine, and in obstetrics and diseases of women and children. But the indifference that had overtaken the section in public health was but temporary, and in 1886, 1887, 1888, and 1889, through the strenuous efforts of Dr. Alexander Hadden, the chairman, and Dr. Henry E. Crampton, the secretary, important topics regarding various matters in public health were presented for the section's consideration. The efficient administration of Dr. H. D. Chapin is too recent to require more than a reference. Suffice it to say that during the past seven years all of the more important questions in hygiene have been considered by this section.

What may we learn from this review of the past history of the academy in its relation to public health? We have seen that active work in sanitation-work intended to enhance the welfare of the public of this metropolis and to serve as a guide for other cities-has been inaugurated by the academy. But there are devoted and disinterested fellows of the academy who maintain that there should be a strict construction of the constitution that states specifically that the object of the academy shall be "the promotion of the science and art of medicine, including the maintenance of a public medical library." They hold that. while this section may consider all topics within its purview, yet neither it nor the academy must do more in the effort to carry out whatever conclusions may be adopted. Does not such action as this savor too strongly of the vox et præterea nihil position? A recently enacted by-law prohibits any section from inaugurating any public action on a matter it has considered without first securing the consent of the academy, so the general body can give the stamp of its approval to whatever work in public sanitation this section might wish to advocate.

There are many questions in public health that are yet to be settled; there is much yet to be done in sanitation, in regard to which the initiative should come from this academy. Take, for instance, the well-known fact that it is but recently that the recorded birth-rate exceeded the death-rate of this city, a disparity due to the carelessness of many physicians, some even fellows of this academy, to give the board of health their co-operation by reporting births that occur in their practice, and an omission that must have the disapproval of this body.

If we take the items of certain communicable diseases and compare the statistics of this city with those of London, we are struck with the excess of the proportion of the mortality to the number of cases reported in New York as contrasted with that of London.

	189	90.	1892.		
	New York.	London.	New York.	London,	
Scarlatina:	-				
Cases	3,087	15,330	7,048	27,095	
Deaths	408	876	977	1,167	
Mortality, per cent	13.2	5.7	13.8	4 - 5	
Diphtheria:					
Cases	4,250	6,420	4,654	7,781	
Deaths	1,262	1,417	1,436	1,856	
Mortality, per cent	29.6	22	30.8	23 . 8	
Typhoid fever:					
Cases	1,141	2,877	1,140	2,465	
Deaths	352	618	400	424	
Mortality, per cent	30.8	21.4	35	17.9	

It does not seem either probable or possible that New York physicians are so lacking in skill, or that either scarlatina, diphtheria, or typhoid fever is here so malignant that this proportion is so much greater than in London. Nor is it altogether probable that the excess is due to the fact that physicians fail to report the existence of such diseases in their practice. The table shows us that the mortality percentage from scarlatina, diphtheria, and typhoid fever was, both in London and New York, but slightly different in 1892 from that of 1890. We are therefore forced to the conclusion that there are certain local factors of environment or administration that must account for the increased mortality from these diseases in this city.

There are problems regarding our water supply, our methods of disposal of garbage, of street cleaning, of tenement-house sanitation, and of food inspection that must be solved before we can successfully grapple with the great problem of disease prevention. And the investigation of such problems by this academy can not but redound to the public welfare and the repute of the investigators.

As the constitution of the academy has provided for the existence of this section, it would seem but just that all subjects relating to sanitary science should be referred here for consideration and report. If committees are created at various times for the consideration of sanitary topics, in so far they encroach upon the legitimate sphere of work of the section and must needs interfere with its usefulness. Two sections of the academy-that on anatomy, physiology, and pathology, and that on materia medica and therapeutics-have lapsed into innocuous desuetude for lack of support and encouragement; and only the most unselfish and zealous devotion can conserve the interest in this Cinderella of the sisterhood of sections. Abler pens than mine have portrayed the possibilities for human welfare that the study and application of the principles of sanitation afford. Hygiene needs no eulogy here. But it is to be hoped that this section—the only one in the academy that affords a common meeting ground for the physician, the lawyer, the engineer, the sociologist, and the layman-may receive increased support from the fellows of the academy, and thus have its influence broadened until its capability for the greatest good to the greatest number is insured.

## Original Communications.

## GONORRHŒAL RHEUMATISM AND ITS TREATMENT.\*

### By RAMON GUITÉRAS, M. D.

History.—Gonorrheal rheumatism has been recognized as a complication of gonorrhea for several hundred years. Petrus Forestus, in 1507, was the first man who wrote extensively on this subject. Musgrave and Baglivi mention it in 1703 as a proof of the syphilitic character of gonorrhea. Hunter considered it connected with gonorrhea only. Eagle, in 1836, considered it due to copaiba and to the improper treatment of gonorrhea. Brandes, in 1854, was the first man to bring it before the public as it is known to-day.

Ætiology; Theories of Cause.—1. First it was regarded as a direct gonorrheal complication, as epididymitis and prostatitis.

- 2. Then it was found that joint swellings might develop after other irritations of the urethral mucous membrane, such as catheterism; and this led to the theory that the gonorrhoal discharge was the source of irritation in the urethra which gave rise to the rheumatism.
- 3. Fournier advocated the theory that it must be due to a specific gonorrhœal urethritis, and that no other form would produce it.
- 4. Thiry and Gurjon maintained that there was no direct connection between gonorrhæa and rheumatism, but that the former, through its depressing effects on the system, favored the development of a diathesis which had up to the time of the disease (gonorrhæa) been latent.
- 5. Guérin, Loraine, and Lasègue considered that gonorrhœa was a general disease, and pointed out the fact that it could produce remote complications as a proof of their theory. They considered the local manifestations of the

disease as a period of incubation, and said that no remote complications would ensue if the disease could be stopped during this period, or not extend beyond it.

- 6. Lewin advocated a vaso-motor theory. He regarded it as a reflex vaso-motor disturbance produced by vaso-motor irritation in the inflamed urethra.
- 7. Gonococci Theories.—In the effusion of certain joints, generally the purulently inflamed, obtained either at autopsy or by puncture, diplococci and cocci have been found. These are alleged by some (a) to be gonococci which had entered into the circulation through the urethral erosions and were afterward deposited in the joints. To them it seemed a true gonorrheal affection. Others (b) denied the presence of gonococci in the joint fluid, considering them as non-specific cocci, and regarded the disease as a mixed infection.

In order to prove the first of these two gonococci theories three conditions are necessary:

- (1) That the micro-organism be similar to the gonococcus morphologically.
- (2) That it be the same in its chemical relations and its reactions to coloring matter.
- (3) That the disease be produced in another by inoculation with the pure cultures.

These conditions have been proved as far as the first two and the urethral inflammation are concerned, but we lack positive proof of the third. Neither do we find any evidences of the gonococcus in the blood or lymph of the individuals affected. Therefore we must agree with the supporters of the second theory and consider it as a mixed affection.\*

Frequency.—This complication occurs in from two to three per cent. of those suffering from the disease. It generally occurs in men. Age has no influence. It is not necessarily connected with a urethritis, but may result from gonorrhœa anywhere—as of the vulva, vagina, and coniunctiva.

Authorities differ somewhat as to the period at which the disease begins, to wit:

Fournier says from the sixth to the fifteenth day. Roustan, not before the third week. Struppi, never before the disease has reached the pars posterior. Loeb, it is a complication of posterior urethritis. Finger, only in the older cases.

Location.—Fournier states that two thirds of the cases are in the knee, one fourth in the ankle, and one fifth in the fingers and toes.

Nolen, in his cases, found eighty-six in the knee, fiftytwo in the ankle, twenty-nine in the shoulder, twenty-six in the hand, fifteen in the hip, and seventeen in the fingers and toes.

Finger, in three hundred and seventy-one cases, found knee, one hundred and thirty-six; tibio-tarsal, fifty-nine; wrist, fifty-three; fingers, thirty-five; elbow, twenty-five; shoulder, twenty-four; hip, eighteen, maxillary, ten; metatarsus, seven; sacro-iliac, four; sterno-clavicular, four; chondrocostal, two; intervertebral, two, etc.

<sup>\*</sup> Read before the Section in Genito-urinary Surgery of the New York Academy of Medicine, May 9, 1893.

<sup>\*</sup> The micro-organisms resembling the gonococcus are not able to penetrate the mucous membrane of the urethra until it has been acted upon by the gonococcus.

Jullien found fifty-nine polyarticular; forty-one monarticular.

Diagnosis.—This disease occurs during an attack of gonorrhea, and follows its course, being governed by its exacerbations and remissions.

There is a tendency to recurrence on fresh infection.

It is less acute than rheumatism, and, although it may begin acutely, it soon changes to a subacute or chronic state.

When this complication sets in the discharge usually remains the same, notwithstanding that some claim it diminishes and others that it increases.

The various forms of this disease are divided and subdivided, after the classification of Finger, somewhat as fol-

- (2) Periarticular (nodose).
- (3) Synovitis tendinum.
- (a) The acute monarticular (arthritis blennorrhoica) is the most frequent form. It begins acutely, or is preceded by a prodromal stage of malaise and tenderness in several joints, followed by a rapid onset of the arthritis; pain very acute or moderate; ædema; redness of the skin; tension considerable at times, but varying with the amount of exudation; fluctuation distinct; temperature elevated three or four degrees for a few days, highest in the sero-purulent variety. The swelling develops rapidly, and is usually in one of the larger joints, as the knee. The pain and fever disappear in a few days, leaving a painless exudation, tending to pass into a hydrarthrosis. This generally disappears in a few weeks. Occasionally, however, it terminates in suppuration. In these cases we have chills and increased temperature during the acute stage, followed by pain, œdema, throbbing, pulsating sensations; the capsule ruptures, and the pus oozes out between the muscles and tendons. This may result fatally in pyæmia, or recovery with ankylosis. Amputation is at times required.
- (b) Hydrarthrosis (gonocele) is a chronic inflammation coming on either directly or as a sequel of arthritis. In direct cases there are no subjective symptoms; exudation takes place into the joint, which therefore increases in size gradually and prevents extreme flexion or extension. Fluctuation is very apparent. This may result in a lax joint or plastic changes, as shown by a crepitation and creaking. Deformittes may follow. Duration varies from a few days to several months.
- (c) Acute polyarticular. This resembles more closely acute articular rheumatism. It develops rapidly, involves several joints, and is painful. It differs from articular rheumatism in that the fever is not as continued or as high; a less number of joints are affected; the joints may be attacked symmetrically, although usually not more than two at a time, and then one after another; it relapses with the urethral discharge; it does not yield so quickly to antirrheumatics, and there is not so much sweating.

- (d) Subacute polyarticular is, next to acute arthritisthe most common form. The symptoms are the same as the acute form, excepting that they are much lighter, especially so in proportion to the amount of swelling present. There is very little elevation of temperature.
- (e) Chronic polyarticular develops after the acute or subacute forms, and is the same as multiple hydrarthrosis.
- 2. Periarticular. Prodromal stage of malaise, pains in the bones, etc. Temperature is quite high at first. The joint swells rapidly. The infiltration is not in the joint, however, but in the periarticular tissue. The joint seems thickened and deformed as in gout. The mobility of the joint is not affected, except that the motion at times becomes too free. Result, complete recovery, or with ankylosis.
- 3. Tendo-vaginitis (synovitis tendinum). This begins with chilliness and slight fever, followed by pains which are migratory in character at first, but which soon become fixed in the sheath of some tendon, which is seen as a doughy, painful swelling. The skin becomes red and afterward adematous. Pain is at times violent; increased by pressure and movement. The former quickly disappears, but the latter lasts for some time. The extensor communis digitorum, the flexor pollicis, and the dorsal flexors of the toes are the ones principally affected. This form is very often combined with arthritis, and, like it, may be serous, sero-fibrinous, or sero-purulent.

Serous resolves completely, or passes into a hydrops.

Sero-fibrinous may cause adhesions between the tendons and their sheaths.

Sero-purulent may end in resolution, adhesions, or suppuration.

Pathology.—This is generally considered with special reference to the contents of the joint, as serous, sero-fibrinous, sero-purulent, and purulent.

In the acute serous, in addition to the hyperæmia and swelling of the synovial membrane and ligamentous tissues, we have a fluid, straw-colored or slightly tinged with blood, containing large epithelioid and white blood cells and albumin.

In the sero-fibrinous we have a similar condition, with the addition of fibrin.

In the sero-purulent we have a greenish colored fluid, containing quantities of pus cells, many of which are fatty degenerated.

Purulent.—In these cases the joint is full of pus; the cartilages are at times eroded; the bones may be bare and the periosteum separated. In chronic cases, the capsule, ligaments, and sheaths of tendons in the neighborhood of the joint are thickened. The cartilages may also be thickened, and atrophy of the muscles near the joint is frequently noticed, due probably to disuse or a peripheral neuritis.

Prognosis.—The serous variety generally ends in complete resolution. It may, however, terminate in hydrops or arthritis deformans, or it may develop into the sero-fibrinous or the sero-purulent variety. The sero-fibrinous and the sero-purulent generally resolve in a few weeks under treatment. They may end in partial ankylosis or even in suppuration.

The purulent variety usually terminates in recovery with ankylosis. It may end in pyæmia.

Other Complications.—Endocarditis and pericarditis occasionally occur complicating a blennorrhagic rheumatism, and sometimes, though rarely, as a direct complication of the gonorrhæa. This generally comes on acutely, the temperature reaching as high as 102° or 103°, accompanied by a feeling of oppression and dyspnæa and irregular and violent heart action. The mitral valve is the one usually affected.

Eruptions occasionally accompany this, generally a purpuric one, though erythema multiforme or nodosum and urticaria may also occur.

Certain eye complications, as iritis, aquo-capsulitis, and conjunctivitis, have at times been noticed.

- 1. Iritis is the most serious of these complications, and resembles the ordinary rheumatic iritis—discoloration, impaired mobility of the iris, contraction and distortion of the pupil, occasionally photophobia, ciliary injection, and a smoky, opaque cornea. On ophthalmoscopic examination this opacity is seen to be due to a number of whitish points collected in the lower half of the cornea, probably the condition of kératite ponctuée described by Panas.
- 2. Aquo capsulitis is an inflammation involving principally the membrane of Descemet, and is the commonest form of complication. In this condition the cornea is more prominent than usual, the conjunctiva is injected, and the fluid in the anterior chamber is cloudy. When iritis is associated, we have its train of symptoms in addition.
- Conjunctivitis occasionally occurs in connection with this disease, and has been principally dwelt upon by Fournier.

Bursitis (gonorrheal). The one under the tuber ischii—giving symptoms of muscular rheumatism and sciatica—is at times inflamed; not so frequently, however, as the one in front of the tendo Achillis and that beneath the os calcis.

Pied blennorrhagique, a complication first described by Jaquet in 1892, often resembles these forms of bursitis in their earlier stages. It consists of an inflammatory process involving the calcaneum and the ligaments.

Complications of the Nervous System.—The spinal cord may also at times be involved. In these cases certain symptoms referring to the sensitive and motor tracts are noticed, as neuralgias, hyperæsthesia, anæsthesia, cramps, atrophy of muscles, increased reflexes, twitchings, etc.

Nerves irrespective of the spinal cord are occasionally involved individually. In this class of complications sciatica is principally noticed, although cases of crural, inguino-scrotal, and other neuralgias are at times observed. They generally complicate the polyarticular type.

There are other complications, as of the palmar and plantar fascias, the ano-coccygeal rhaphe, etc., which occasionally occur.

Treatment.—This is very varied and generally very unsatisfactory. When an attack of rheumatism occurs, either alone or as an accompaniment of gonorrhea, the first thought is to give an antirrheumatic. On our list of antirrheumatics used in the treatment of this disease we find salicylic acid, salicylate of sodium, salol, oleum gaultheriæ, colchicum, and the

alkalies and salts of potassium, lithium, and sodium. Between salicylic acid and salicylate of sodium, the latter seems to be preferable and to act more efficaciously. This can be given in doses of fifteen grains every four hours, and seems to be of decided benefit in many cases of the acute monarticular and polyarticular types during the first few days of the attack, decreasing the fever and the severity of the pains. Here, however, its efficacy frequently ceases, and whereas it has reduced the disease to a subacute condition, it does not seem able to accomplish a cure.

Salol has, in my practice, supplanted the other salicy-lates. It has the same effect in reducing the temperature and diminishing the severity of the pains, besides being far more agreeable to take, not causing the nausea and gastric disturbances that are wont to accompany the use of salicylic acid and salicylate of sodium. This I use in acute cases in doses of five to fifteen grains three times a day, the ordinary dose being ten grains. When severe neuralgic pains accompany this, phenacetin makes a valuable adjunct. Here I give two grains and a half of each in pill every three hours, and from five to ten grains of salol in addition night and morning.

Oleum gaultheriæ is of value in both the acute and subacute stages of this variety of rheumatism, and comes the nearest to a specific of any of the many remedies used. I am in the habit of beginning with five grains three times a day and of running it up to two drachms and even three drachms in the twenty-four hours. A good way to prescribe it is five to twenty drops every two hours in milk.

Colchicum is also of service, especially in the later cases. It cures not only by its systemic action, but also by its action on the gonorrhea itself, and was at one time quite extensively used in the treatment of urethritis. It often produces good results alone, but works better combined with salicylate of sodium and iodide of potassium.

Alkalies are of service throughout the disease and have a double action, antiblennorrhagic and antirrheumatic, and by means of their diluent properties they decrease the acidity of the urine and thus tend to diminish the urethral irritation. For this purpose the effervescing carbonate of lithium tablet, or one composed of the bicarbonate and citrate of potassium, five grains each, every three hours, can be used.

Internal Antiblennorrhagics.—Copaiba, cubebs, and oil of sandalwood are all good on account of their action through the urine on the mucous membrane of the urethra. They tend to diminish the urethral inflammation without irritating it, and are therefore of more service in treating the cause than astringents or other injections. I am in the habit of putting my patients on antiblennorrhagics whenever they develop rheumatism during the earlier stages of the disease, at a time when the discharge is still acute or subacute.

Local Antiblennorrhagics.—Treatment of the urethral inflammation by astringent injections, both anterior and deep, or by irrigation, or again, by local applications through the endoscope, seems to aggravate the rheumatism rather than to benefit it. The washing out of the bladder likewise seems to have an irritating effect. In fact, so unsatisfactory has been my experience with local antiblennorrhagic treatment during these attacks, that I have instantly discontinued them and substituted the internal antiblennorrhagics in their stead.

Surgical Treatment of the Urethritis.—In case strictures happen to be present I have found it of decided value, and many obstinate cases have quickly recovered after an internal urethrotomy. Sounds, on the other hand, seem to aggravate rather than to benefit the condition.

General Treatment.—Iodide of potassium is of value as an alterative, and seems to benefit the subacute and chronic conditions when there is thickening about the joint with no marked ankylosis.

Donovan's solution will also at times be of service through its alterative action.

Tonics are of service when the individual is cachectic or "below par." Of these iron is the most efficient, either alone or combined with strychnine or quinine. Syrup of the iodide of iron is of the greatest benefit when an alterative as well as a tonic effect is desired.

Strychnine is especially beneficial when the nervous system has been weakened by the attack.

Quinine has been regarded by some as a specific and given in large doses as such. It probably has no other effect, however, than that of a tonic.

Baths, especially sulphur, are of decided benefit in the subacute and chronic varieties.

Local Treatment.—Counter-irritation is beneficial in all forms of the disease, and generally in proportion to the severity of the treatment. Tincture of iodine painted on night and morning until vessication is produced affords relief, but does not seem to have as speedy or as beneficial an action as nitrate-of-silver solution when used in the same way.

Blisters seem to be one of the most efficacious methods of producing counter-irritations, and they should be applied generously either in several small areas over an inflamed joint or as one large blister covering nearly the entire joint surface. The former seems to be most valuable in the acute cases, the latter in the chronic.

The Paquelin cautery at times in the acute stages produces immediate relief of pain and hastens a curative process. I doubt, however, whether its effects are as good or as lasting as those of the continued counter-irritants mentioned above.

Icthyol ointment, fifty per cent. in lanolin, has given me by far the best results of any local counter-irritant application. The counter-irritation produced by the icthyol is apparently very light, as it takes several applications to make any pronounced redness of the skin. The effects of the ointment are, however, at times marvelous, and two or three nightly rubbings will sometimes give permanent relief in patients who have been suffering for weeks. These cases are generally subacute or chronic—indolent ones where no marked tissue changes have occurred.

Absorbents.—Local treatment tending to cause absorption is of the greatest value after the acute symptoms have passed away. Under this head I include massage, electricity, and pressure from elastic bandages.

Massage by the method known as pétrisage, combined with Swedish (passive) movements, and followed by pressure with elastic bandages or stockings, produces the best results, after the acute stage has disappeared, of any treatment either external or internal. The massage increases the circulation in the joint and stimulates the absorption of the exuded matter by the veins and lymphatics, and the rubber bandages by pressure prevent further exudation. This, of course, should not be resorted to when there are any evidences of pustular inflammation.

Electrization by the galvanic current is of decided service (the strength usually used being from five to fifteen cells). I am in the habit in the hospital cases of having massage given one day and galvanism the next.

Potassium-iodide and mercurial ointments are of doubtful value. The former in some cases has seemed to be efficient, but whether the beneficial action was due to the virtues of the iodide or to the massage necessary to rub it in I am not prepared to say. I use it occasionally in an ointment of lanolin, in the strength of one to eight, in chronic cases where thickening and adhesions are present.

Other Local Remedies.—Leeches are frequently valuable in cases of the monarticular variety during the acute stage. They seem to afford by their depleting action temporary relief.

Poultices are good when there is much pain in the acute stages. They are, however, of especial value in the suppurating forms of the disease before resorting to surgical interference.

Alternating hot and cold douches have in some chronic cases seemed to act beneficially.

Cold applications, either in the form of cold cloths or an ice bag, are also grateful during the acute stages in the monarticular variety.

Surgical Treatment.—When pus has formed and pyæmia is threatening, free incisions should be made and the joint irrigated with bichloride solution, I to 10,000, followed by a boric-acid solution. In cases where the suppurating process has involved the surrounding tissue amputation may be necessary. In other suppurative cases where the joint is partially destroyed resection may be performed.

79 WEST FIFTY-FOURTH STREET.

### THE USELESSNESS OF A MYDRIATIC

IN EXAMINING AN EYE

FOR THE PURPOSE OF PRESCRIBING GLASSES.\*

By D. B. St. JOHN ROOSA, M. D., LL D., SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL: PROFESSOR IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL

In 1876 I wrote a paper, which was read before the International Congress of Ophthalmology, on the relation of blepharitis ciliaris to ametropia. It was stated in that paper that many cases of this disease were connected with, and caused by, errors of refraction, and that the condition

<sup>\*</sup> Read by title before the Medical Society of the State of New York, February 7, 1894.

in such instances could not be cured unless the refraction was first corrected. This view caused some discussion, but I believe that its conclusions were finally considered by experts in ophthalmic disease to be, in the main, accurate. The point was also then made that it was impossible, in a large number of cases occurring in young persons, to determine whether or not a refractive anomaly existed unless paralysis of the ciliary muscle had been produced by the use of a mydriatic, and it was argued that the reason that many observers did not find this relation existed between blepharitis and ametropia was that they did not thoroughly test the refraction with the aid of a mydriatic. I still think that this view is correct, but I did not ask your attention for the purpose of saying any more upon this subject of the relation of certain diseases of the eyelids to uncorrected errors of refraction. I merely wished to bring to your attention, as preliminary to the present discussion, the fact that very early in my practice I resorted to the thorough use of a mydriatic before attempting to determine, the in case of young people with asthenopic symptoms, whether or not glasses should be worn, and if so, what. I continued this practice of using a mydriatic for the purpose of measuring the eye up to the year 1888, both in my hospital and private practice. It is a method of treatment entirely satisfactory in its final results, but it is extremely disagreeable to the patient; it involves a great deal of time, and it is tedious in the extreme to the practitioner. In many instances it was found to have been unnecessary, except that the positive determination that no considerable degree of astigmatism existed was made. It often settles the fact that there is no astigmatism sufficient to be corrected, and that only hyperopia or myopia, which can be very well determined by the ophthalmoscope, exists.

While in Paris, in 1887, and seeing a little of the work of Dr. E. Javal, I was greatly surprised to find that he, who had been an enthusiastic advocate of the use of atropine for as long a time if not longer than I had myself, and who was in the habit of prescribing glasses from the results obtained by the atropine, now, since he had perfected the ophthalmometer—the instrument for measuring the cornea—had entirely abandoned the practice. I found also that Dr. Bull, formerly on my staff, concurred in these views.

But this thorough use of atropine, which I believe was properly insisted upon as the only sure means of accurately determining the refraction, was somewhat abused by those who recommended it when there was no apparent spasm of accommodation, and for persons in middle life or advanced years. After 1876, papers began to appear from neurologists and young ophthalmologists, showing that they used atropine in what I should term an indiscriminate way-for example, in persons beyond forty years of age, where there can be no question, except in entirely extraordinary and exceptional cases, of spasm of accommodation. These writers ignore the physiological principle of tone in a muscle. In other words, presbyopes, who needed nothing but a few minutes' testing with glasses, were put under the influence of atropine, and persons with an eye so nearly normal that its deviation from emmetropia could be expressed by a positive spherical glass of one or two dioptres, were

considered to be subjects for glasses because under atropine they would accept, say + 0.50 D., when really all the belladonna had done was to remove the tone of the muscle. Something must be allowed for this in every human eye. The attempt to convert an ordinary eye into an ideal one, which in some quarters is said to be the proper course, I deprecate, founding my opinions primarily upon the work of Donders and Loring, both of which authors dwelt properly, as it seems to me, on the natural tonicity of the ciliary muscle. Most observers have long since come to the conclusion that the hypermetropic eye is the average eye of the human race, excluding myopia, and that it is a condition which of itself can cause no inconvenience until presbyopia is reached, when to the congenital axial elongation of the eye must be added flattening of the lens and rigidity of the ciliary muscle caused by time. Then, as everybody knows, a glass will be required for the presbyopia plus the hypermetropia.

When I found Javal measuring the cornea, and being satisfied with that as a means of determining the refraction, I undertook the same practice myself, and after six years of experience I am convinced that the use of a mydriatic to determine what glass should be worn is entirely unnecessary if the ophthalmometer is used. The great object in using a mydriatic was not to determine how much hypermetropia existed - that can be approximately estimated, although not always with complete accuracy, with the ophthalmoscope—but it was used to determine if astigmatism existed, and if so, of what degree. Now this can be determined in a very few moments in the vast majority of cases-in, I think, as large a proportion as ninety-nine out of a hundred-by measuring the cornea alone, for lenticular astigmatism, although it was the kind possessed by its great discoverer, Dr. Thomas Young, about ninety-five years ago, very rarely exists, and in general considerations it need not be taken into account. Early in the investigations of astigmatism, Donders showed just how much corneal astigmatism the lens would overcome by its oblique position. This observation has been verified by the work of Javal, many others, and myself. In a very large practice in refraction cases in the Manhattan Eve and Ear Hospital for the last three years, my staff and myself have not used a mydriatic, except in the most exceptional cases, for the purpose of testing patients for glasses. We have never had such satisfaction in our prescriptions, and we have relieved our patients of a great loss of time and ourselves of a great burden in work. I commend this method to the respectful consideration of my fellow ophthalmologists. If the ophthalmometer is used, and the difference between the vertical and horizontal meridians of the cornea is once fairly established, the rest of the prescription becomes a matter of a very short time. Besides this, I believe, as I have attempted to show in a paper published in the Medical Record,\* that in young persons with asthenopia, caused by an error of refraction, who have as much as a dioptre of corneal astigmatism, it will usually be sufficient to correct the astigmatism, and to allow the hypermetropia to be cared for by the ciliary muscle.

### A STATISTICAL RECORD OF FIVE THOUSAND CASES OF SMALL-POX.

BY WILLIAM M. WELCH, M. D.,

PHYSICIAN IN CHARGE OF THE MUNICIPAL HOSPITAL FOR INFECTIOUS DISEASES, PHILADELPHIA.

(Combuled from page 3.30.)

In the next table is illustrated, first, the efficacy of recent vaccination as performed in infancy, and, secondly, the gradual loss of vaccine protection as the individual grows older:

Table VIII.—Showing the Cases classified as to Age Periods of the Patients, and also as to their Vaccine Condition in each of these Periods.

	Admitted,	Died.	Per cent. of deaths.
Under One Year: Unvaccinated	78 2	57	73.07
ONE TO SEVEN YEARS: Unvaccinated	404	208	51.48
Vaccinated in infancy, good mark  " " fair mark " " poor mark	10 10 15	 I 1	10.0
Total number vaccinated	35	2	5.70
Seven to Fourteen Years: Unvaccinated	222	71	31.98
Vaccinated in infancy, good mark	55 28	2 2	3 · 63 8 · 69
" " poor mark		9	, 15.25
Total number vaccinated	137	13	9.48
FOURTEEN YEARS AND UPWARD: Unvaccinated	1,038	681	65.60
Vaccinated in infancy, good mark		122 93	9.07
" poor mark		280	28.16
Total number vaccinated	2,967	495	16.68

It can not be questioned that, in a large city like Philadelphia, where gratuitous vaccination is provided for the poor and improvident class of the community, there must be a very much larger number of children under one year old vaccinated than unvaccinated, and yet it is seen by the table that seventy-eight of the latter were admitted to the hospital, and only two of the former. The unvaccinated perished in the proportion of 73.07 per cent., while both of the vaccinated of course recovered. One of the vaccinated children was eleven months old; had been vaccinated two months previously; showed a good cicatrix; had varioloid in an exceedingly mild form, the eruption consisting of only six small vesicles; and the child was at no time scarcely ill at all. The other vaccinated case had the disease so indistinctly marked that, following the diagnosis of varioloid as recorded in the Record Book, I find a mark of interrogation, which, interpreted, means that the diagnosis was somewhat doubtful. These facts show that small pox among unvaccinated children under one year old is very common and fatal; also that among vaccinated children at this age the disease is very rare, and, when it occurs at all, it is no more to be feared, so far as danger to life is concerned, than ordinary vaccina.

In children between the ages of one and seven years small-pox is, of course, very common among the unvaccinated, and occasionally it is seen in a very mild form among the vaccinated; but death never results where there is evidence of thorough vaccination, except from some serious complication. It is seen in the table that one death occurred under the head of "fair" vaccine mark. In this case the child was about a year old, a foundling, badly nourished, having disordered digestion, and was very feeble. The eruption consisted of only a very few small vesicles. Death resulted from sheer debility. Very little need be said of those classified under the head of "poor" vaccine scars, as the vaccination in all such cases was either imperfect or spurious.

In the next age period—seven to fourteen years—it is worthy of note that the death-rate among the unvaccinated cases is very much lower than at any of the other age periods. Possibly the explanation of this is that the recuperative powers of life are most active at that age, or that some of the depressing habits common in later life, such as intemperance and the like, have not yet been formed. At this period of life post-vaccinal cases of small-pox increase considerably, and occasionally death occurs from the disease, even after quite thorough infantile vaccination. These facts clearly indicate that the vaccination of infancy is apt to lose at this period more or less of its protective power.

The last age period noted in the table-fourteen years and upward-illustrates, in the first place, how large is the number of youths and adults who have never enjoyed the prophylactic power of vaccination. Among this class, too, the death-rate is seen to be considerably higher than that of the corresponding class in either of the two preceding age periods. The table also proves in a very indubitable manner, by the great increase of post-vaccinal cases of small pox at this age period, that vaccination in infancy can not be depended upon to confer protection against the disease in the later life of the individual. There are therefore two important facts prominently brought forward in this table: First, that recent vaccination confers absolute, or almost absolute, protection against small pox, and, secondly, that when vaccination has been performed in infancy revaccination is required at, if not before, the age of puberty.

My experience leads me to place implicit confidence in the efficacy of revaccination, although the statistics presented in Table IX are somewhat vague and indefinite, and do not therefore fully or clearly demonstrate the real merits of the measure. The table simply contains the relevant data as obtained from the patients who claimed to have been vaccinated in infancy and subsequently revaccinated, together with the general results.

In tabulating the cases represented in the following table I have been obliged to accept the statements of the patients, first, as to the fact of revaccination, and, secondly, as to the time when it was performed. Their testimony as to whether or not it was successful I have found very unreliable. To use their own language, they often said "it took a little" or "the arm was very sore," and frequently they did not remember whether it "took" at all, but would point to a

of revaccination. Not infrequently marks were pointed out as the result of revaccination which were an exact counterpart of one or more other marks present on the arm, and which were known to have resulted from the primary vaccination. It is evident, therefore, that it would be very difficult to say how many of the cases recorded in the table should be regarded as authentic examples of small-pox occurring after successful revaccination. Some, I think, should be so regarded.

The more positive evidence of the efficacy of revaccination is to be found in the fact that persons recently revaccinated with effect do not take small-pox when freely exposed to the infection. During my service of twenty-three years no resident physician of the hospital, no nurse, laundress, cook, or any other employee who was properly revaccinated before entering on duty has taken small-pox. Perhaps I should except a female nurse who was revaccinated on the first day of her residence in the hospital with almost typical result. In the course of about two weeks I noticed on of evidence furnished by the patients.

mark which they said they had always believed was the result | the forehead of this nurse, near the edge of her hair, one or two variolous vesicles, which were preceded by but little if any febrile disturbance. At any rate, she was at no time disabled from performing her usual duties.

> What vaccination has done for these employees, whose duties have necessarily brought them in the closest possible contact with the infection of small-pox, it will do for any or all who fully avail themselves of its protective influence. I am firmly of the opinion that if all persons were properly vaccinated in infancy and again at the age of puberty Jenner's prediction as to the power of this agent to extirpate small-pox from the globe would soon be realized.

> In the following and last table which I shall present are contained the principal data at hand in regard to the cases or alleged cases of second attacks of small-pox. There is found in it also the same element of uncertainty as to the authenticity of many of the cases as existed in the preceding table, though perhaps to a less degree, and this uncertainty is owing to the same cause-namely, the unreliability

Table X .- Showing the alleged Cases of Second Attacks of Small-pox.

43	24	7 years.	Not vaccinated.		.' Some pitting.	Unmodified.	Death.	About eighteen pits on face. It is possible for these to have resulted from chicken-pox.
44	41	18 years.	Not noted.		. Well marked	. Greatly modified.	Recovery.	Eruption only papular.
4.5	50	2 weeks.	Vaccinated.	No visible marks.	No pitting.	Modified.	44	Says the alleged previous attack of small-pox occurred about the time she was vaccinated, and that two of her sisters had small-pox at the same time and are pitted.

It is certain that very many of the cases recorded in the foregoing table should not be regarded as true cases of recurrent small-pox. For instance, where it is seen that a smallpox patient has never been vaccinated, shows little or no pitting, and is suffering from an unmodified form of the disease, it is more than probable that there has been no previous attack. Slight pitting, when present, is not necessarily proof of such an attack having existed, for the pitting may have resulted from chicken-pox, which disease, I well know, is often mistaken for small-pox. So also all those cases having a history of thorough vaccination in infancy, if characteristic pitting of the alleged previous attack is absent, should be regarded as very doubtful cases of recurrent small-pox. It would be very exceptional indeed for a person first to take vaccina, then small-pox, and subsequently a second attack of the disease.

There is no doubt that a few of the cases recorded in the table should be regarded as genuine second attacks of small-pox, but in most such cases the disease was exceedingly mild—so mild, indeed, in some instances as scarcely to be recognizable. I have never yet seen an unmodified, or even a severe, case of small-pox occur in a person who was deeply and characteristically pitted from a previous attack. Such cases I know may be found on record, but it has not been my fortune to meet with them. I might say, furthermore, that during my many years of service no person has been admitted to the hospital twice suffering from any form of the variolous disease. In view of all these facts, I can not help believing that second attacks of small-pox are much rarer than is generally supposed.

821 NORTH BROAD STREET.

### SCANTY MENSTRUATION.\*

BY FRANKLIN TOWNSEND, A.M., M.D.,

Mr. President and Gentlemen of the Society: Through the polite courtesy of our worthy president, Dr. Bendell, and Dr. Andrew F. Currier, of New York, I have been invited to take part in this general discussion on menstruction and its abnormities. That portion of the subject allotted to me being Scanty Menstruation, and, as naturally happens at these meetings, time for the reading of papers on all subjects must of necessity be limited, because of the vast amount of work to be gone through with during the session, I feel that, like the first portion of my subject, the term "scanty" may well apply to whatever oral flow I may now make before you. As I understand it, scanty, like profuse menstruation, indicates one of the ordinary departures from what we all understand as characteristic of a normal or healthy monthly discharge of menstrual blood from the uterus, to any deviation from which the term "paramenia" might aptly apply.

One of the most interesting works on all the peculiar diseases of womankind to me is that of Dr. Robert Barnes, of London, under whose tuition I had the opportunity of gaining much in an early training which proved so beneficial to me in after years. This author classifies the subject of disordered menstruation under the one term "amenorrhœa," including deficiency of the flow. But it would seem to me that terms of this nature, like so many others we as physicians have to use in medicine, are inadequate to express that which we really mean. Many different conditions may exist besides the one that is most prominent; at the same time, this main symptom is that which attracts the attention of the patient, and which eventually causes her to seek medical advice. It must, therefore, become evident to us all that to thoroughly analyze our patient's condition, and to discover, if possible, what are the associated phenomena connected with the case, as well as to what the cause of the most prominent symptom is due, becomes our serious duty.

With these preliminary remarks allow me, then, to take up some of the various causes which seem to induce "scanty menstruation," as a part of the general subject under discussion.

To my mind the most fertile soil to develop such a malcondition is to be found in the state of the blood, and by this I mean that when the blood plasma is wanting in its normal constituents, and where the blood globules are deprived of their natural ingredients, both caused by malnutrition, the general body must suffer, and the term "chloro-anæmia," therefore, has thus been given to express such a condition. As to this class of chlorotic patients there could be much said, more especially by the specialist in nervous diseases; and as I write, I can bring to mind much of solid worth as coming from such men as Goodell and Mitchell, of Philadelphia, who not only recog-

nized the curious neurotic elements connected with such cases, but also through this knowledge made application of the same by instituting a course of treatment which has availed much for suffering women.

Should we draw a comparison between the society woman of to-day, the humble, hardworking peasant, and the Indian squaw or stout negress from our southern latitude, it would be difficult to believe that all could have sprung from the same parent stem. Indeed, observation goes far to prove that those of the female sex who are not exposed to depreciating influences can compete in strength and endurance with the men of their races. From such facts as these, logically reasoning, the human female, if properly developed and placed beyond conditions which might militate against her physical well-being, would in no degree be the inferior of the male. The present customs consonant with the age, in dress, exercise, and general hygienic details, seem to be the vice which tends to bring about this condition of "chloro-anæmia," with the result of a disordered menstruation and the scantiness of its normal flow.

Long ago Dr. Thomas A. Emmet pointed out the importance of not permitting young girls who were just coming into maturity to exercise their mental capacities at the expense of their physical capabilities. There is but little question that such advice was good; and instead of the young ladies of to-day being encouraged to engage in outdoor sports, very few have such opportunities, and I imagine that it would be wiser for them and their general health were they thus properly trained and instructed. Want of air and exercise in deteriorating the blood, enfeebling the two great systems of the body, the nervous and muscular, should be properly classed as two of the most important factors as causes for many of the menstrual disorders of the day. The necessity for the proper maintenance of these systems must be recognized, and the mens sana in corpore sano surely becomes essential to a healthy condition. Girls of tender age are required to apply their minds too constantly to master studies beyond their mental capacity, because of the so-called "progress of the times"-the results from such training being a rapid development of the whole cerebro-spinal nervous system, precocious talent, refined and cultivated taste, etc.; but on the other hand comes as a result the morbid impressibility that implants itself upon the generative organs. And added to this class of such functional uterine morbidities, among which is to be placed scanty menstruation, would naturally come the subject of the improprieties in the manner in which women clothe themselves. I can not better than express with Thomas, of New York, that the dress adopted by the women of our town may be graceful and becoming; it may possess the great advantage of developing the beauties of the figure; but it certainly is conducive to many menstrual troubles. The process of respiration is entirely done by the thoracic muscles; the diaphragm taking a most important part in the performance of this physiological process, the proper performance of this function must therefore be interfered with by the current custom of tight lacing. "The habit of contracting the waist in such

<sup>\*</sup> Read before the Medical Society of the State of New York at its  $\mathbf{e}\mathbf{i}\mathbf{g}\mathbf{h}\mathbf{t}\mathbf{y}\text{-}\mathbf{e}\mathbf{i}\mathbf{g}\mathbf{h}\mathbf{t}\mathbf{h}$  annual meeting.

a manner actomplishes what the surgeon does when he holds a broken rib in place by a snug bandage." Thus come many troubles to the pelvic organs, which lie in such close relation, and which must, therefore, partake of functional difficulties. In estimating the effects of direct pressure upon the position of the uterus, its extreme mobility must be constantly borne in mind. No more striking evidence of this fact can be cited than that as proved by the use of the Sims speculum in our usual examinations.

Other causes might be enumerated as giving rise to this form of disordered menstruation, as imprudencies during the menstrual nisus, or after parturition, prevention of conception, or induction of abortion, etc. But time will scarcely permit of any particular discourse upon these subjects. Suffice it to say, that they remain unfortunately as factors of causation, and I am afraid before much improvement can be attained for their removal, a desire must first be cultivated in the minds of those who are the sufferers, and, as a rule, I regret to say that in my experience neither the desire nor the appreciation of the importance of such a subject toward the requirement of physical excellence sufficiently exists among the more refined and better class of the women of to-day.

Chloro-anæmia, as a physiologico-pathological condition, may and can well exist, resulting in scanty menstrua tion. As to climate and its influences upon this function (menstruation) one might say something, but the subject is so well known to us all that I shall refrain from speaking of it, except to mention it as an additional cause of the malady in question. Serious disease of the kidneys or of the lungs, as well as many of the zymotic troubles so frequently encountered, are also to be regarded as contributing causes toward disturbing the normal function of menstruction, often bringing about a scantiness of the flow, and even at times causing it to cease entirely. Often a leucorrheal discharge at periodical intervals in women thus diseased takes the place of a normal flux, which subject has been thoroughly discussed by Dr. Currier, of New York, at different times before this society.

In my experience I can not say that I have met with other causes for scanty menstruation. It may be possible that many forms of uterine tumors or other pathological growths connected with this organ are productive of it, yet the most pertinent factors seem to me to be those as already cited, chloro-anæmia being the most prominent of all. With this in mind, therefore, it would appear from a purely physiological standpoint that treatment should be directed toward correcting, so far as is possible, this condition.

According to Virchow, chlorosis or chloro-anæmia is to be distinguished from leukæmia or leucocythæmia, in that the entire number of the blood globules is less. In leukæmia the colorless corpuscles seem to take the place of the red ones, and a true diminution in the number of the cellular elements in the blood is not produced. In chloro-anæmia the elements of both kinds become less numerous, without the occurrence of any disturbance in the numerical relation between these different corpuscles. This sage

pathologist goes on to say further that "anatomical observations indicate that the foundation of chlorotic ailments are very early laid, for the aorta and the larger arteries are usually, and the heart and sexual organs frequently, found imperfectly developed."

To originate a new function, to bring to perfection a hitherto unexercised power, must make great demands upon the physical strength, and often, unfortunately, these demands are larger than are required for its continued activity. Numerous instances must come to our mind where, after menstruation has become fairly established, chloroanæmia suddenly and unexpectedly makes its appearance, suppressing either partially or completely the flow. In many such cases emotion frequently plays an important part. Jealousy, disappointments of various kinds, especially those offending the affections—the spreta injuria forma-are often the immediate antecedents, which eventually result in impoverishment of the blood. Naturally, in the treatment of such conditions as described, iron as a remedy par excellence is the first suggestion that appeals to the physician, and such may be true-but, I might add, only in its timely and proper administration, which requires more judgment than is commonly shown-and from clinical experience I can well agree with Barnes that this drug is only tolerated after vascular excitability or irritability is assuaged; it then becomes readily assimilated. To bring about this result most satisfactorily is best done by the use of salines, and I have found that the old preparation of the liquor ammonii acetatis, when freshly made, fulfills the purpose most admirably. After the use of this or other salines iron can be given with most decidedly beneficial

Electricity, too, as suggested by many, holds a most important place as a factor in the treatment of this disorder. Again I can agree with Dr. Currier's statement made before this society, that I fail to see much benefit arising from the use of manganese in any of its various forms. Other drugs might be mentioned, all useful in their way, in the treatment of this malady, each one having its champion to second its merits, but time will not permit at present of speaking further in this direction.

To summarize, then, I would say:

- That scanty menstruation is most usually the result of malnutrition in both young and middle-aged women, married or single.
- 2. That the primary seat of this trouble lies in the condition known as chloro-anæmia.
- 3. That its treatment must be directed in an intelligent manner toward rectifying this condition.

And, lastly, that a persistent patience must be persevered in with the various forms of treatment laid down, if a permanent cure is to be expected.

The Medical Association of Georgia will hold its forty-fifth annual meeting in Atlanta on April 18th, 19th, and 20th, under the presidency of Dr. W. II. Elliott, of Savannah.

The Royal Academy of Medicine of Naples, we learn, has made Dr. J. Mount Bleyer, of New York, a fellow.

### A NOTE ON THE

### EMPLOYMENT OF NUCLEIN SOLUTIONS.

By JOHN AULDE, M.D.,

Nuclein therapy possesses many attractions for the physician. The idea of administering a substance which shall stimulate cellular activity through the medium of the white blood-corpuscles or their nucleus is so closely associated with the vital processes that it becomes especially seductive to the physiologist and the clinician. Nuclein therapy, however, is not a complete therapy in itself; it is merely a branch or subdivision of cellular therapy, which is more comprehensive in its scope. Just as nucleins augment the nuclear activity of the leucocytes, thus increasing the antiseptic power of the blood, we have other remedies which enact a different rôle, as in the case of iron and phosphorus, both of which may prove useful to the organism by supplying it with some element that is wanting. Thus, liver "stimulants" are sometimes useful because they produce sufficient irritation of the hepatic cells to enable them to do more and better work.

Nucleins introduced into the blood perform a twofold function, since they possess distinct antiseptic properties, and besides they act as stimulants-that is, being poisonous or toxic, they irritate the protoplasm, whether coming into contact with it in the arteries, veins, or intercellular fluid. This double action is most marked when nuclein solutions are exhibited during a period of profound depression, or even that of moderate disability, due to a disorganized state of the blood, such as we see in anæmia and malarial toxæmia. In the latter class of cases I have noted marvelous changes occurring in the blood within a week, and sometimes even in the course of a few days. For example, the red corpuscles on first examination will exhibit a crenated appearance, with few or none having a round-like, normal contour; when dried, many of the red discs will be found broken or split, and not infrequently we shall be able to discover clear indications of malarial poisoning, with or without the vegetable micro-organism associated with that disease. In the course of a few days after beginning the administration of nuclein solutions large numbers of healthy corpuscles can be found in the field, and along with them a multitude of the unhealthy discs. When we consider the immense number of red blood-corpuscles in the blood of a healthy human being, estimated at two hundred trillions, we can form only a faint conception of the rôle played by so-called "blood medicines"-if they prove efficient.

In certain directions and under certain restrictions and limitations I am satisfied that nuclein as a remedial agent possesses powers far beyond any remedy ever introduced into medical practice, as the following brief reports will show. Indeed, it appears to be Nature's own remedy, and with it the clinician will be able to accomplish the most surprising results in the treatment of various diseases.

Case I. Nasopharyngeal Catarrh, with Chronic Bronchitis.

—Harry, aged thirteen years, weight sixty five pounds, was brought to me a few weeks ago from an adjoining State suffer-

ing from deafness, naso-pharyngeal catarrh, and chronic bronchitis, all of which is said to have resulted from an attack of influenza which occurred in the early part of the winter. Upon holding a watch to the ear, it was impossible for the boy to hear it unless placed close to the head, although the nerve supply was intact. An examination of the external auditory meatus discovered inflammatory deposits along with impacted cerumen, and the effervescence which occurred when a small portion of hydrogen dioxide was added convinced me that the secretion was not healthy. The additional local treatment consisted in the application of dry aristol. There was an almost constant cough, hawking of mucus from the head, and the child had no appetite. Internal treatment for the first four days consisted in the administration of a fiftieth of a grain of potassium bichromate at intervals of two or three hours, so that five doses should be taken during the day. Under this treatment the condition of the ears improved as well as the nasal trouble, but there was no perceptible change in the condition of the bronchial apparatus.

On the fifth day of treatment nuclein solution was given in small doses at intervals of two hours, and not only produced a notable effect upon the appetite and digestion, but also upon the bronchitis. The father said, at the end of ten days, that the boy was then eating about three times as much as before, and further, that he had gained ten pounds in weight since beginning treatment. The hearing had so far improved that the patient could hear a watch at a distance of fifteen inches, the cough and bronchitis had subsided, and improvement was perceptible daily.

Case II, Amygdalitis .- Mrs. H., aged twenty-two years, had been suffering for two or three days from amygdalitis, which domestic treatment failed to relieve. The pulse was rapid, the temperature 100°; there were chilly sensations or "creeps" running up and down the back, and deglutition was painful. This patient began taking nuclein solution at once, a dose being administered at the office, and felt some relief from this dose. The remedy was continued at intervals of an hour, and after taking the sixth dose all pain and other disagreeable symptoms subsided (this was during the afternoon and evening), and the patient had a comfortable night. There was no further occasion for medication on the following day, and thus ended the attack. In previous attacks she had frequently been kept in the house for a week or more, and had used gargles freely of every imaginable description. I may add that I had attended this patient previously under the same conditions, where the results were equally satisfactory, and could give a long list of similar cases equally flattering as evidence that it was not a mere coincidence.

Case III. Anamia.—Mrs. G., aged forty years, rather spare, was a patient some years ago, but for the past five years she has resided near London, England. When suffering from indigestion she derives benefit from a modified Fothergill pill, and last summer wrote, asking me to send her some of the black pills along with some little pellets which I had given her on one of her trips for seasickness. At the time of writing she said she was under treatment, or had been under treatment, for anamia. With the package of medicine I inclosed some nuclein solution in the form of granules, telling her that if she had not fully recovered from the anamia she might derive benefit from the little pellets.

To this letter, with instructions, the patient replied, October 29th, as follows:

"After writing to you I became much worse and my heart was terribly weak. Dr. E. wished me to consult Dr. De Haviland Hall, in London, as his opinion was, I must lie up entirely for a time, to give my heart a perfect rest. Dr. Hall entirely agreed, so I had to lie up for two weeks, and was treated with iron and arsenic. By the time your letter came I was much better and had made some blood. Two days after I was sent to the seaside, where I remained three weeks and derived much benefit, so I saved the granules until more needed. On my return I again became very pale, and my eyelids had not much color, so I commenced taking the medicine, and now write to tell you the result. After two or three doses I noticed a difference, and in a few days I had more blood than I ever remember. So it has proved a great success, and I am saving the remainder for another time."

Under date of January 24, 1894, this patient writes the following account of her further experience with the nuclein, although, of course, she does not know what she is taking:

"My object in writing is to ask for some more of the black pills for liver and indigestion and also some granules for amemia. I find both benefit me more than any medicine I can obtain here. I have again been suffering from anæmic symptoms, and began taking the granules, and am now better. I have some left, but do not wish to be without them."

I forbear making comment on this, as the evidence is quite clear and conclusive, showing that the effects were produced without any hypnotic influence or suggestion on my part, as I only mentioned in the letter of instructions that, in case she had not fully recovered from the attack of anæmia, she might derive benefit from the use of the pellets, taken according to the directions.

CASE IV. Masked Malaria .- Miss M., aged fifty years, has been suffering for a long time from some occult ailment which has resisted the most earnest solicitations of several competent physicians, as well as sanitarium treatment and travel. She suffers from alternate constipation and diarrhea, is very nervous, and has sleepless nights, being usually unable to sleep before four o'clock in the morning. The appetite appears to be fairly good, but she lives principally on starchy foods; likes "grits" for breakfast, but wants her other foods highly seasoned. This condition has existed for several years, and, although she has periods when excessive languor takes possession of her, she has become quite philosophical about the matter. The sleepless nights are the most objectionable, although chloral, sulphonal, and other hypnotics and anodynes, she says, have failed to produce any apparent benefit. An examination of the blood under the microscope shows that there is not a single healthy red corpuscle in the whole field; they are crenated, broken, misshapen, and many of them appear to contain pigmentary deposits. The first examination was made with a onefifth-inch objective, magnifying five hundred diameters, and the dry specimen, twenty-four hours later, with a one-fifteenthinch oil-immersion lens, magnifying a thousand diameters, both examinations showing practically the same result.

After taking nuclein solution for three days, a second microscopic examination was made, when it was found that the perfect red discs had developed so that they existed in about the proportion of one good one to twenty or twenty-five poor ones. The patient meanwhile, with a regulated diet, had greatly improved; she slept very well the second night, and was able on the following day to go out and walk with comfort, and had more strength than for a long time. I may add that the patient is still improving and the number of healthy red corpuscles rapidly increasing, and there has been no more difficulty with the bowels.

Case V. Malarial Toxamia.—Mr. B., aged thirty years, had an attack of malaria during the year 1881, and again in the autumn of 1889. Since the last attack he has suffered from muscæ

volitantes. These spots can be seen by looking toward the lightand have been constantly present for four years and a half.

There is no distinct history of malarial symptoms during the past few years, although, when closely questioned, the patient thinks he has days each week nearly when there is a noticeable languid feeling. The pulse-rate is 72, temperature 97.5° F., and there is no apparent evidence of miasmatic influence at the present time. An examination of the blood discloses that there is not a single healthy red corpuscle, all being crenated or broken.

Treatment by nuclein solution for six days produced no material change, except that the patient noticed that he had rather more free movements of the bowels, with considerable discharge of sulphureted hydrogen. He had also felt disposed to be a trifle more active than usual. A second examination of the blood showed that the number of healthy corpuscles was about in the proportion of one to ten, but there was a multiplicity of microcytes floating in the field when the specimen was fresh. I should have stated that at the first examination I found a number of spherical bodies, one flagellum, some crescentic bodies, and quite a number of corpuscles having indications of the presence or the effect of the action of the vegetable microorganism found in the blood in malaria.

A third examination of the blood two days after that last described failed to discover any microcytes, the proportion of healthy corpuscles had perceptibly increased and the patient said that for two days past the condition of the eyes had measurably improved, the floating spots being less distinct than formerly.

Whether a permanent cure will result from this treatment I am at present unable to say, but with the remarkable changes which have occurred in the blood in the short time mentioned (eight days) it does not seem unreasonable to anticipate favorable results from the treatment adopted. At the time of beginning treatment there was no doubt of the presence of malaria, and the rapid changes which have taken place in eight days being favorable, all lead to the same conclusion. In all clearly marked malarial cases coming under my observation since beginning the use of nuclein solutions, I have never known the remedy to fail in a single instance, and when we bear in mind that it is necessary to medicate no less than two hundred trillions of the corpuscles, it must be admitted that a little time will be required.

1411 WALNUT STREET.

## THE OCCLUSION OF THE POST-NASAL SPACE BY SYPHILITIC ADHESION.

BY E. HARRISON GRIFFIN, M. D.,
LECTURER ON DISEASES OF THE THROAT AND NOSE
AT BELLEVUE HOSPITAL MEDICAL COLLEGE;
ATTENDING SURGEON FOR THE THROAT AND NOSE,
OUTDOOR DEPARTMENT OF BELLEVUE HOSPITAL, NEW YORK

The subject of this paper has received little attention from the hands of practicing laryngologists. The cases have rather been ignored and the adhesions have been looked upon as something the hand of the surgeon had better leave to the care of Nature.

Cohen reports one case in his book. Bosworth takes up the subject more thoroughly and gives some interesting statistics of cases that have been reported.

I reported in the Medical Record of January, 1888, a

case in which I had operated for this deformity. I saw my patient five years after my operation; the opening I had made had remained open, and his voice, which had been lost for two years previous to the surgical interference, was clear and loud.

The statistics of twenty-two of these cases that I have collected are as follows: Adhesion of the palate occurred to the pharynx by syphilitic ulceration in one case four-teen months after the initial lesion, in three cases two years, in five cases three years, in eight about the fourth year, in two the sixth year, in one the seventh year, in one the tenth year, and in one the fourteenth year.

Complete occlusion of the nares by syphilitic adhesion occurred in three cases, adhesion of the palate to the pharynx with the uvula free in two cases, loss of the uvula and adhesion of the palate to the pharynx with a small opening into the post-nasal space in seven cases. The remainder I will classify as simple adhesions.

One side of the palate may be destroyed more than the opposite side; in these cases the adhesion will be higher up and give the palate the appearance as if it sloped to the side of the lesser destruction.

This deformity is generally the advent of tertiary syphilis. I can refer to five cases that have occurred in my practice where the uvula was lost and adhesion occurred by ulceration, due to inherited syphilis.

The resulting deformity was the same as occurred by the syphilitic ulceration.

One case that came under my notice in an adult with this adhesion gave a history that pointed to gangrene of the palate and pharynx as the cause of the trouble.

The swallowing of a strong caustic, if the patient survived the ordeal, might be a factor in producing this deformity.

The adhesion is due to the syphilitic ulcer that forms on the palate and pharynx. Both of these must participate in the ulceration to produce an adhesion. Two raw or denuded surfaces must be brought together before this malformation can occur.

I have had cases where the ulceration extended from one pillar of the fauxes to the other and as low as I could see down the pharynx, and where the ulceration ran high up into the post nasal space, recover without any adhesion, simply because the pharyngeal surface of the palate was not involved in the ulceration.

To have the ulceration confine itself to the pharynx or the palate alone is very rare. The surfaces are brought together so often in nasal breathing and in the act of deglutition that an ulceration beginning on one of the parts quickly infects its neighbor, and means, if it is not quickly arrested, a destruction of tissue and perhaps a partial or complete adhesion of the palate to the pharynx.

I know of nothing more insidious or more liable to be passed over than a syphilitic ulceration occurring in the vault of the pharynx or behind the palate. The symptoms point to everything but a syphilitic ulceration.

The nose is generally occluded, and presents upon examination the appearance of a hypertrophic or an acute rhinitis.

The patient is generally affected with a cough produced by the discharge from the ulceration dropping down into his larynx. This symptom is liable to be mistaken for a bronchitis, and the true trouble only recognized when the ulceration has made extensive progress. The diagnosis is easily made by the rhinoscopic mirror, or in some cases the ulceration can be seen by lifting the palate up with a probe.

Pain is very seldom a factor in these cases. A slight headache and fever may be present, produced by the acute rhinitis that generally accompanies syphilitic ulceration of the palate or the pharynx.

The absence of pain is the reason for the great deformities that are so often seen in this region. The patient treats his cough with some home remedy, and only applies for treatment when he notices some defect in his speech or a difficulty in swallowing.

Vomiting may be present, produced by the constant irritation and tickling in the throat from the discharge from the ulcer.

I had one case where the vomiting had lasted three weeks before I saw the case. The patient vomited everything that she swallowed. Even milk she could not retain on her stomach. I cleaned the ulcer and gave her direction how to do it at home. At the next visit she reported that the vomiting had ceased after I had treated her throat, although I had started her on thirty grains of iodide of potassium, with directions to increase at each dose.

The quicker the patient is brought under proper internal medication the better. The iodide of potassium, given in large doses in plenty of water on a full stomach, will generally obtain control of the disease in twenty-four to forty-eight hours. The ulceration yields readily to treatment, but large doses of this drug are generally indicated in this stage of the disease.

I have controlled an ugly ulceration in one case with ten grains of the drug, while in another I have given two drachms four times a day before I could make any impression on the ulceration.

The quicker the ulceration is healed, the less the deformity. With this idea in view, anything that will help healthy granulation to form, should not be overlooked.

Local treatment is very important. I place the lotio hydrargyri nigra, diluted a fourth to a half, at the head of the list as a wash or a gargle in this affection.

Peroxide of hydrogen, diluted with water a fourth or a sixth strength, is an excellent preparation to clean off these ulcers. Dobell's solution or Seiler's tablets form a useful cleanser.

After the parts have been thoroughly cleaned, both in the throat and the post-nasal space, a little albolene oil can be sprayed in, followed by iodoform, aristol, or europhen, the latter forming a perfect unguent over the part.

At times, even with the closest care, when the ulceration has been extensive, an adhesion of the palate to the pharynx is hard to prevent. In some cases I have been able to break up the adhesion with the little instrument I shall describe presently.

An operation is generally best even for a partial adhesion. Dilatation is slow and uncertain.

In an operation on this deformity of the palate try and save as much tissue as possible, yet make the opening large and generous, remembering that the two ends are liable to unite by granulation.

A silver probe bent and covered with cotton, passed through the nose down between the palate and pharyngeal adhesion, will give the point for operation.

I use a curved knife made for me by Tiemann. I give a picture of it below. It is sharp at the point and on both sides, so it can be made to cut either from right to left or vice versa.

Before operating cleanse the nose thoroughly of any mucus or crust formations; this applies also to the pharynx. Spray into the nose a four-per-cent. solution of cocaine and touch the cicatricial tissue in the pharynx with a twenty-per-cent. solution till the parts are well under the anæsthetic. If this is done thoroughly, the operation is painless, and if ten grains of quinine have been given for three nights previous to the operation, the hæmorrhage is slight and easily controlled.

It is a simple contrivance and in my hands has produced good results in this class of cases.

The operation is easy, the discomfort arising from the obstruction to nasal breathing is eliminated, and the palatopharyngeal space can be re-established by this little instrument.

112 WEST FORTY-FIFTH STREET.

# A PECULIAR CASE OF MORPHINE IDIOSYNCRASY,

WITH UNUSUAL SYMPTOMS.

By M. ELEAZARIAN, M. D.

Mrs. C., aged twenty-six, of nervous temperament, previous health good. Suffering from great shock and prostration. Sci-

atica with severe pains generally, resulting from injuries received by having been thrown from one of the surface cars in this city. Three days after this injury I gave her a hypodermic injection of a quarter of a grain of sulphate of

morphine with a one-hundredth of a grain of sulphate of atropine to relieve her sciatic pains. I remained with the patient fifteen minutes after the injection and then left her feeling quite comfortable, but as yet she had not experienced the effects of the drug thus injected. In twenty minutes after (from the time I left her), I was hastily summoned to my patient. On my arrival, I found her in a cold, clammy perspiration, the pupils contracted to the size of a pin's head, respirations from five to eight a minute, and in a heavy stupor; there were frothing at the mouth and spasmodic contractions of the muscles of both arms and opisthotonus. After I had applied the usual means of restoration and of arousing the patient, she complained of great dyspnea and noises in the head resembling, as she said, the waves of the ocean. Remaining with the patient long enough to feel that she was entirely out of danger, I left her.

On my next visit in the morning, ten hours after, she felt as well as ever, complaining of great exhaustion only.

106 East Twenty-fourth Street.

Introduce the knife well between the cicatricial binding morphine we to relieve here.

Introduce the knife well between the cicatricial binding and carry it as high as it will go; then turn the instrument down, so it will cut from the upper surface of the adhesion to the lower point of resistance. Cut well toward the pillars of the fauces and see that the edges of the palate are freed from the pharynx.

If there is an adhesion of both sides, repeat the operation on the opposite side.

A little chromic acid on a probe, applied to the cut surfaces, will often prevent them from reuniting. It will also even the edges.

If any ragged edge should be left, it can be easily trimmed with a pair of curved scissors. Do not try to remove any crust that may form upon the cut surfaces when the healing process begins. A crust will prevent the parts from reuniting, especially if the patient is under syphilitic treatment

I advise my patient after the operation to buy the instrument that is pictured below. It was made for me by Tiemann & Co. and can be easily manipulated by the patient.

The blades are introduced behind the palate and pressure on the handle will separate the blades so they will dilate the parts from a fourth of an inch to an inch and a half.

Examinations for the Army Medical Corps.—The surgeon general has issued the following circular: "In view of

the possibility of the reduction of the medical corps from a hundred and twenty-five to ninety assistant surgeons, by action of Congress at its present session, and to save possible loss of time and expense to candidates if such action be taken, the examinations appointed for March and April, 1894, will, by order of the Secretary of War, not be held until further notice. It is probable that, if the corps should not be reduced, the examining board will be convened in the fall of 1894. Of this, notice as early as possible be given."

Change of Address.—Dr. Edward B. Coburn, to No. 329 West Fifty-eighth Street. THE

NEW YORK, SATURDAY, MARCH 24, 1894.

#### BRONCHITIS IN INFANTS.

This important subject was discussed at a meeting of the Section in Pædiatrics of the New York Academy of Medicine held on March 8th. Dr. William H. Thomson spoke of the numerous peculiarities which this disease presented during the first few months of life. It usually started, he said, from some exposure of the surface of the body. Wetting of the back of the neck was especially apt to be followed by pharvngitis with secondary bronchitis. Children who perspired freely about the head and neck during sleep were particularly prone to bronchial catarrh. One of the chief means of prevention consisted in sponging the neck with cool salt water at bedtime and protecting it from cold during sleep. The younger the child, the more serious was the disease. This was due largely to the very small relative muscular strength of the infant, the expiratory muscles being especially feeble. The respiratory passages, especially the pharynx, readily became clogged therefore, and the difficulty was thus greatly increased. The mechanical effort of breathing was an important factor in reducing the strength of the child, and sudden physical collapse was not uncommon. Special attention should be directed, therefore, toward keeping the bronchial passages clear. An "expectorant" cough should be encouraged. Such a cough should be carefully distinguished from a "non-expectorant," or irritant, cough. An "expectorant" cough should not be discouraged, but sedatives might properly be given to control an irritant element.

In a paper on the management of bronchitis in infants under a year of age, Dr. Charles G. Kerley referred to the importance of loosening the bands and clothing, that the child might have perfect freedom in breathing. The position should be changed frequently to prevent the gravitation of fluids into dependent portions of the lung. General baths and packs were not indicated, but tepid sponging might be employed to advantage, especially if there was slight fever. Dyspnæa with hard, tight cough might often be relieved by a mustard bath at 100° F. If the disease became deep-seated, with rapid breathing, cyanosis, and dry cough, the use of the steam spray, either plain or medicated, would aid materially. It might be used for fifteen minutes every hour or even more frequently. Counter-irritation to the chest was the most important of all measures of treatment in young infants. Camphorated oil, applied with considerable friction, might be all that was required. A mixture of camphorated oil, turpentine, and aromatic spirit of ammonia was especially serviceable. In more severe cases a mustard paste proved more efficacious. One part of mustard was combined with five parts of flour. It was spread between two pieces of muslin and might be left from ten to thirty minutes. It disease of the bodies of the cervical vertebræ and of the inter-

application might be repeated two or three times a day, and in severe cases more frequently, until the skin became sensitive.

In few conditions was the relative importance of local measures so great as compared with drug treatment. Castor oil, in doses of from three to five drops every two hours, sometimes had a decidedly good effect. A tablet containing a minute dose of tartar emetic and ipecac might also prove of value. If it was desired to produced emesis, fifteen drops of wine of ipecac might be given every fifteen minutes. For irritability and restlessness, small doses of potassium bromide and chloral were admissible, or a very small dose of Dover's powder. The administration of the ordinary sweet and nauseous cough mixtures did great harm by clogging the bronchial tubes and disturbing the digestion. Their use should not be tolerated.

### THE ACADEMY OF MEDICINE'S NEW NATIONAL SANITATION BILL.

Several weeks ago we felt constrained to express our disapproval of a bill that had been prepared by the National Quarantine Committee of the New York Academy of Medicine. and been introduced into Congress, looking to the establishment of a national board of health. The committee itself seems now to have felt that the bill was objectionable, for it has prepared a new one that differs radically from the first. The full text of the new bill will be found on page 378 of this issue of the Journal. Substantially, this new bill meets with our approval, but there are a few matters of detail that we think ought to be set straight.

It will be observed that section 9 puts the matter of maritime quarantine into the hands of the Secretary of the Treasury -that is, by plain implication, into those of the Marine-Hospital Service, where it properly belongs, for it is not to be supposed that the Secretary of the Treasury would or could manage it in any other way. In view of the excellent work that has been done by the members of that corps, we think it would have been graceful and decorous to mention the corps in this section of the bill. We are informed, indeed, that that was done in the original draft, but that the passage was afterward taken out simply because it seemed to be unnecessary.

Section 22, we think, should be made a little more specific. If the bill were to become a law with that section in its present state, there would be nothing to restrain the commissioner of public health from spending the considerable sum of \$1,075,-000 within an hour after the organization of the bureau, in case he was so disposed.

### MINOR PARAGRAPHS.

### RETROPHARYNGEAL ABSCESS.

At the Section in Orthopædic Surgery of the New York Academy of Medicine two papers were recently read on Retropharyngeal Abscess and its Treatment, by Dr. Berg and Dr. Townsend. Dr. Berg divided these abscesses into two formsthe acute and the chronic-and said that the latter were due to vertebral discs. In both forms the cavity of the pharynx was encroached upon so as to cause a gurgling, nasal voice, and to impede respiration. The acute form was accompanied with pain, and the swelling was situated more or less superficially and should be opened by an incision in the posterior wall of the pharynx. In the chronic form, due to Pott's disease of the vertebræ, the collection was situated beneath the anterior common ligament of the vertebræ and the prevertebral fascia, which were difficult to burrow through and guided the pus behind the carotid vessels to the posterior triangle of the neck. Treatment must be directed to both the disease of the vertebræ and the abscess itself. Rest in the recumbent posture and immobilization of the neck by suitable apparatus were indicated for the bone disease. The danger of hamorrhage or of cedema of the glottis resulting on account of the position of the abscess indicated its immediate evacuation, whatever might be the views entertained in regard to opening cold abscesses in general. For many reasons an external opening, on either the anterior or the posterior border of the sterno-cleido mastoid, was to be preferred; but when this was impracticable an opening might be made in the pharynx by means of an aspirator, a trocar and cannula, or a guarded knife. Of these means the aspirator was preferable, and the cavity of the abscess might be washed out with a solution of iodoform in oil or ether.

### THE GERMICIDAL ACTION OF GALLANOL.

A RECENT number of the Lyon medical contains the report of a series of exhaustive experiments by MM. P. Cazeneuve, Rollet, and Nicolas to ascertain the germicidal value of gallanol. The action of the drug was tested on five microbes, that of anthrax, the Staphylococcus aureus, the Bacillus pyocyaneus, the Eberth germ, and the Bacillus coli communis. The experimenters arrived at the conclusions that gallanol in excess completely destroyed the vitality of the micro-organisms, that in a relatively weak solution their development was diminished, and that in an attenuated solution, while their growth was not materially affected, their pathogenic powers were destroyed. It was shown that the drug was an invaluable remedy in the vegetable parasitic diseases; while destructive to the microorganisms, it was perfectly non toxic to the general system. Gallanol possessed such active germicidal properties that there was no doubt that it could be employed with great benefit in the infectious diseases as an abortive remedy.

## THE SAN FRANCISCO MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The committee of arrangements for the forthcoming meeting, of which Dr. R. H. Plummer, of San Francisco, is the chairman, has very properly issued a circular setting forth some of the beauties of that city. We can bear testimony that they are not overdrawn in the circular, and we hope it will reach every member and delegate, for there must be many members of the medical profession in the United States who have no adequate conception of the Golden City's attractiveness. Every one who can go to San Francisco to attend the meeting should do so.

### THE EOAGLAND LABORATORY, BROOKLYN.

The annual course of post-graduate drill in microscopy and pathology is now in progress at this institution. It will continue until April 15th, at which time the course in bacteriology will be resumed, to continue until June 1st. These courses are under the direction of Dr. J. M. Van Cott and Dr. Ezra H. Wilson.

#### ITEMS. ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 20, 1894:

DISEASES.	Week end	ing Mar. 13.	Week ending Mar. 20.		
	Cases.	Deaths.	Cases.	Deaths.	
Typhus	0	0	()	0	
Typhoid fever	11	5	11	3	
Scarlet fever		18	178	12	
Cerebro-spinal meningitis	0	0	0	0	
Measles	387	27	331	23	
Diphtheria	167	44	200	41	
Small-pox	23	3	28	8	

The Death of Dr. Albert C. Stanard took place on Monday, the 19th inst., at the New York Hospital, where a few days before he had been operated on for a recurrent attack of disease of the vermiform appendix. The deceased was at one time a member of the house staff of the hospital.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 11 to March 17, 1894:

Fisher, Walter W. R., Captain and Assistant Surgeon, is granted leave of absence for six months, to take effect on or about May 1, 1894, with permission to go beyond the sea.

By direction of the President, the retirement from active service, March 13, 1894, by operation of law, of Bartholf, John H., Major and Surgeon, under the provisions of the act of Congress approved June 30, 1882, is announced.

STRAUB, PAUL F., First Lieutenant and Assistant Surgeon, is relieved from duty at Fort Riley, Kansas, and ordered to report in person to the commanding officer, San Carlos, Arizona, for duty at that post, relieving McVex, Harlan E., First Lieutenant and Assistant Surgeon. Lieutenant McVey, on being relieved by Lieutenant Straub, will report in person to the commanding officer, Whipple Barracks, Arizona Territory, for duty at that post.

A board of officers, to consist of Greenleaf, Charles R., Lieutenant Colonel and Deputy Surgeon General; Hartsuff, Albert, Lieutenant Colonel and Deputy Surgeon General; and Pope, Benjamin F., Major and Surgeon, is appointed to meet at the call of the president thereof, at San Francisco, Cal., for the examination of Hall, William R., Captain and Assistant Surgeon, with a view of determining his fitness for promotion, as contemplated by the acts of Congress approved October 1, 1890, and July 27, 1892. Captain Hall will report in person to the president of the board for examination at such time as he may designate.

### Society Meetings for the Coming Week:

MONDAY, March 26th: Medical Society of the County of New York; Boston Society for Medical Improvement; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

Tuesday, March 27th: New York Dermatological Society (private); Buffalo, N. Y., Obstetrical Society; Medical Society of the County of Lewis, N. Y. (quarterly); Boston Society of Medical Sciences.

Wednesday, March 28th: New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Metropolitan Medical Society (private), New York; Auburn, N. Y., City Medical Association; Medical Society of the County of Albany, N. Y.; Philadelphia County Medical Society; Berkshire, Mass., District Medical Society (Pittsfield).

Thursday, March 29th: New York Academy of Medicine (Section in Obstetrics and Gynæcology).

## Metters to the Editor.

CHROMOGENIC BACTERIA.

Boston University Medical School, March 7, 1894.

To the Editor of the New York Medical Journal:

Six: In the issue of the Medical Journal for March 3, 1894, Dr. Ager describes an interesting species of bacillus which is chromogenic in the presence of glucose. Last July I observed this same phenomenon in connection with Bacillus cyanogenus, the bacillus of "blue milk." This bacillus is common in north Germany and elsewhere in Europe, causing epidemics of blue milk, but under successive cultivations in the laboratory soon loses its power to produce the color. It is also said that comparatively new cultures rapidly deteriorate in this respect in America.

In agar or gelatin tubes, when glucose is present, a striking pale-indigo blue color appears directly below the growth, and the growth itself often becomes of a steely metallic blue. I have not observed any tubes in which the color was complete throughout, and in many it extends but a little distance beyond the growth. A few experiments, substituting dextrose and levulose (sugars in the same group) for glucose, gave the same result, but with lactose chromogenesis does not occur.

In the presence of glycerin a rather characteristic brownish color is formed, but in a much longer time. The blue color with glucose generally appears within a few days, but I have known it to be a week and even longer in coming, and in one case to have failed entirely.

The value of glucose in the determination of species is only just beginning to be appreciated. Further study will probably show many more species which spontaneously produce color in its presence. There are valuable acid reactions shown by litmus or other indicators. Gas formation in "Smith tubes" is another important species-characteristic.

I can see no reason why glucose should not be added to gelatin for plating purposes in order to distinguish those species which produce color in its presence, though as yet too little is known of its reactions to do more than suggest this and wait until all the species one is likely to meet with have been studied in connection with it.

Marion Hamilton Carter.

## Proceedings of Societies

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of February 6, 1894.

The President, Dr. M. ALLEN STARR, in the Chair.

A Portable Air-tight Alcohol Lamp.—Dr. WILLIAM M. LESZYNSKY exhibited such a lamp, made of metal, which he

stated he had found very serviceable in applying cupping glasses. It also served all the purposes of a spirit lamp. The ordinary methods of applying the cupping glasses were very annoying and sometimes painful to the patient. In the cups with the rubber bulbs the rubber was apt to get hard and crack.

Electrical Reactions and their Value in Diagnosis and Prognosis.—The President said that he had seen statements from various sources, some very dogmatic and others skeptical, in regard to the value of electrical tests as an aid to diagnosis and prognosis in various forms of nervous disease. A careful review of the literature of nervous diseases would reveal to any one that most men who had written books on this subject had gone right back to Erb's original article, published in 1872, in the first edition of von Ziemssen's Cyclopædia, and had recopied Erb's diagrams and statements. Individuals who had had many opportunities of making electrical tests had noticed from time to time that their results did not correspond with the statements laid down by Erb. Their results, however, were not made public, or else they tried to explain them away, as if there were something wrong with them. A discussion on this subject, therefore, would be very timely.

Dr. C. L. Dana opened the discussion and took up the subject of the value of electrical reactions in spinal lesions. In connection with this subject he had particularly studied a certain number of cases in which he had been able to test the reactions many times in the course of the disease. The tests had been made in cases of anterior poliomyelitis, progressive muscular atrophy, and bulbar palsy, also in one or two cases of facial palsy and locomotor ataxia.

It was absolutely necessary, Dr. Dana said, in making any comparative statements about results, that we should understand how the reactions had been taken by each observer and what he meant by reaction of degeneration. The reactions were subject to such variability, and it was so easy to deceive one's self, that the operation required an extremely judicial state of mind and great care. In the tests made by himself, he had employed an indifferent electrode, of about the size specified by Erb; this was to be tied down, not held by the hand, so that there were no variations in the amount of pressure. For the active electrode he had employed a small pointed electrode the surface of which measured one square centimetre. By means of this one could get the muscular irritability at different parts of the muscle, could see whether the contractions were sluggish or not, and could also learn the diffusibility of the contraction, which was a form of reaction that had not been sufficiently noted. If an electrode with a large surface was employed the diffusible reaction was not brought out with any certainty. The small pointed electrode could also be shitted to the motor point of the nerve, and thus the nerve reaction be obtained. In some cases the strength of the current required was so great that the point electrode gave rise to too much pain; in such a case he employed the ordinary-sized electrode. The electrode was first placed on the body of the muscle and reaction obtained with a gradually increasing current, and then the same reaction with a gradually decreasing current. These reactions were compared with those on the opposite side and the operation repeated two or three times with a proper interval between to allow the muscle to rest.

The three points that he had particularly investigated in connection with spinal lesions were: First, the relative irritability of the two poles; second, the character of the reactions—i.e., whether they were sharp or sluggish, or sluggish and diffuse; and third, the course of the variations of the reactions in the different stages of the disease.

With regard to the relative irritability at the positive and

negative poles, many of the recorded cases merely showed that the cathode exceeded the anode in eliciting irritability, without giving the exact number of milliampères required to produce contractions. Dr. Dana said he considered this an inaccurate method of making the measurements. In all reports it should be carefully put down how many milliampères were necessary to produce a positive-pole contraction, and then a negativepole contraction, or vice versa. In this way, by following the course of the disease, we should find that each pole had a definite course of increased and decreased irritability in accordance with the progress of the disease. The speaker exhibited a number of diagrams which he had prepared, showing the course of the polar irritability in several cases of progressive muscular atrophy, in two cases of anterior poliomyelitis, and in one case of double facial palsy; in the latter case he had been able to make daily examinations of both sides of the face for a number of weeks. His observations went to show that there was a difference between the course of the polar irritability in neuritis and that in progressive muscular atrophy and poliomyelitis. In neuritis there was a pronounced steady rise in the polar irritability, while in the spinal lesions it was very slight or absent. So far as his observations went, there was a true degenerative reaction in progressive muscular atrophy, as there was in poliomyelitis, but it was only observed in certain stages of the disease. In all the descriptions of electrical degenerative reactions it was stated that in normal muscles and in partly degenerated muscles the reactions were sharp and quick, but that when the muscles became degenerated the reactions were sluggish or vermicular. Further than this, with the point electrode there was a diffuse contraction of the muscle—i. e., the whole belly of the muscle and even the adjacent muscles would contract. This diffusibility of the contraction Dr. Dana said he considered equally important with the sluggishness, although it did not always take place. It was better seen with the anodal contraction. In conclusion, Dr. Dana thought we had to revise many of our views of reaction of degeneration, but it was too soon to formulate new views.

Dr. W. M. Leszynsky continued the discussion, confining his remarks more particularly to the value of electrical reactions in cases of traumatic neuritis. His method of making the examination, he stated, was very similar to that outlined by Dr. Dana. The conclusions drawn by him were as follows:

- 1. The value of electricity as an accessory method in diagnosis and prognosis of disease of the peripheral nerves is not so universally recognized as its importance demands.
- The result of this procedure often furnishes corroborative and conclusive evidence where only a provisional diagnosis has been made.
- 3. The necessary technical skill in successfully pursuing such investigations and correctly interpreting the result can only be acquired through special study and practice.
- The use of the faradaic current alone is quite sufficient for diagnostic purposes.
- 5. As a rule, the galvanic current is supplemental to the faradaic, and in the absence of faradaic irritability in nerve and muscle it is of the greatest service in prognosis.
- The discovery of the reaction of degeneration is not an essential feature in the diagnosis as to the situation of the lesion.
- 7. The peripheral nerve fibers possess an inherent power of regeneration which seems almost unlimited, the length of time required for the completion of the regenerative process varying from a few weeks to seven years or more. Therefore, in severe forms of injury, the cause, degree, and character of damage to the nerve are often of greater importance in prognosis than the demonstration of the reaction of degeneration.

- 8. The presence of reaction of degeneration, or partial reaction of degeneration, is not incompatible with the preservation of motility in the same area. This paradoxical condition has been found in cases of lead poisoning and a few others, but thus far the cause has been inexplicable.
- Strong currents are only rarely necessary. The weakest current that will produce a distinctly perceptible reaction is all that is requisite.
- 10. A decrease or disappearance of faradaic irritability in nerve and muscle simply denotes an interference with the nutrition in the course of the motor tract between the multipolar cells in the anterior horn and the peripheral nerve distribution. It does not enable us to judge of the nature of the pathological process.
- 11. The character of the reactions does not differ, whether the lesion is situated in the cells of the anterior horn, the anterior nerve roots, the nerve trunks, or their ultimate distribution. The same rule holds good in reference to the various cranial motor nerves and their nuclei, such as the facial, hypoglossal, and spinal accessory nerves.
- When the farado-muscular irritability is lost, no reaction can be obtained by a rapidly interrupted galvanic current.
- 18. The secondary current from an induction coil is the one generally used in testing faradaic irritability. Owing to its high electro-motive force, the resistance encountered in the moistened skin may be disregarded.
- 14. The difference in the poles of the faradaic current is only a relative one, and can not be determined by the usual tests as applied to the galvanic current. The electro-motive force in the secondary coil is greater at the "break" than at the "make." The electrode that is felt to be the stronger in its action is usually considered as the negative or so-called "faradaic cathode."
- 15. In some apparently healthy individuals the musculospiral nerve fails to react to strong currents applied with the "faradaic anode," while a comparatively weak current from the "faradaic cathode" calls forth a quick response.
- 16. In a case of undoubted peripheral paralysis the faradaic irritability may be preserved, but it almost invariably requires a stronger current to produce muscular contractions than upon the healthy side (quantitative decrease). [Dr. Leszynsky said he had never seen a case where this could not be demonstrated within a few days after the onset of the paralysis.]
- 17. The character of the muscular reaction demands attention. A slow and labored contraction associated with decrease in faradaic irritability denotes degenerative changes.
- 18. The faradaic irritability may return in persistent cases of peripheral paralysis without any perceptible improvement in motility.
- Electro-diagnosis is inapplicable in paralysis of ocular muscles.
- 20. When the farado-muscular irritability is lost upon skin excitation, its presence may be demonstrated in the muscle for a longer time by means of acupuncture.
- 21. If electricity is to be of any service in ascertaining whether the nerve trunk has been divided or not, as a result of traumatism, the examination must be made as soon after the injury as possible. We can then determine at once if specia surgical interference is necessary. Should two or three weeks elapse before such examination, it will be impossible to state whether the absence of reaction is due to traumatic neuritis or to complete division of the nerve. Exploratory incision would then be called for.
  - 22. The tests with the galvanic current require adequate

apparatus and a working knowledge of the relationship between electro-motive force, resistance, and current strength. It also requires much time, patience, and perseverance; hence its unpopularity.

The President spoke of the value of electrical reactions in cases of multiple neuritis. He reviewed the conclusions of Nothnagel, Pal, Gowers, and others on this subject, and gave the histories of a number of cases of multiple neuritis that had come under his observation. The first case reported was one of general alcoholic multiple neuritis, with total paralysis in both arms and both legs. In this case, within two months after the onset, when the paralysis was extreme and when no voluntary movement was possible in the muscles of the arm, forearm, or hand, the electrical reactions had differed completely in these localities. In the arm there was a diminution of response to both currents without polar changes; in the forearm there was a loss of faradaic response, with diminution of galvanic response, without polar changes; in the hand there was loss of faradaic response, with diminution of galvanic response and polar changes.

In two other cases of alcoholic multiple neuritis very great variations were present in muscles which were equally paralyzed. In a case of diphtheritic paralysis there was a total loss of contractility to faradaism, but there were no polar changes to the galvanic current. In another case of diphtheritic multiple neuritis, in which ataxia rather than paralysis was a marked symptom, an interesting fact was noted. There appeared to be a slight weakness in the right supinator longus muscle. The electrical reactions of this muscle, however, were found to be normal, the reaction to faradaism being prompt and the cathodeclosure contraction greater than the anode-closure contraction. For purposes of comparison, the left supinator longus was simultaneously tested, there being no voluntary paralysis of this muscle whatever. It was found that the reaction to galvanism in this muscle showed polar changes, the anode-closure contraction being greater than the cathode closure contraction, although there was no reduction in the faradaic response. Here, then, was an observation which confirmed Pal's statement that electrical changes were sometimes present in muscles that were not paralyzed.

Every possible change to electrical reactions might be present in muscles affected in the course of multiple neuritis. The conclusion was inevitable, therefore, that to the electrical changes no very great diagnostic significance could be assigned. In the cases cited there was no parallelism between voluntary power and electrical condition. Voluntary power in all the cases seemed to return before the electrical reactions became normal. Therefore we could not project a reaction line upon a chart into the future and say that at a certain date, when the electrical reactions became normal, the voluntary power must necessarily return. Electrical reactions, while of some interest, were not to be taken as of great importance in the diagnosis of multiple neuritis.

Dr. B. Sachs discussed the value of electrical reactions in dystrophies. In regard to the general subject of reaction degeneration, the speaker said he had been forced to the conclusion that there were only two points of value. The first and most significant feature of reaction degeneration was the loss of faradaic response. The second was the sluggishness of the contraction. The variability between the anodal and cathodal contraction was extremely great, and he had long since abandoned the idea that the relationship between the two could be utilized in all cases for the purpose of either diagnosis or prognosis. Physiologists had demonstrated with considerable plausibility that the electrical excitation of nerves and muscles depended largely upon the rapidity and succession of single

shocks. In muscles in which the faradaic contractility seemed to be absent, if the interruptions were diminished, one could often get a contraction, whereas one would not get it with the ordinary faradaic machines in use. Dr. Sachs said he believed that reaction degeneration was present in any given case if the faradaic response was absent. He agreed with Dr. Dana regarding the variations in polar irritability in different stages of anterior poliomyelitis and other diseases. In Erb's diagrams, which had been so extensively copied, he did not distinguish between anodal and cathodal response. He made no distinction between the two poles. Dr. Sachs said he had found the greatest possible variability in the action of the two poles. In many cases, particularly in peripheral-nerve palsies, he had found that the cathodal excitability was increased as long as the disease lasted. After full power had returned the faradaic excitability might still be diminished or lost for a period of time varying between several weeks and a year. In exceptional cases the faradaic response remained normal from beginning to end, but the galvanic changes were pronounced.

The speaker said it was well to divide muscular dystrophies into two classes—namely, primary muscular dystrophies and the spinal amyotrophies. In the pure dystrophies we rarely got a definite reaction degeneration—i. e., there were rarely entire absence of faradaic response and marked sluggish reaction, except in the very last stages of the disease, when so little muscular fiber was left that we could not expect to get either faradaic or galvanic response. In primary muscular dystrophy, therefore, there was no typical reaction of degeneration. In other than primary muscular dystrophies we got a very strong resemblance to the typical reaction degeneration. In progressive muscular atrophy of spinal origin, reaction of degeneration might be present in its entirety; but we often found partial reaction of degeneration and other irregular types of electrical reaction

As regarded the value of electrical reactions in diagnosis and prognosis, Dr. Sachs said he was fully in accord with the statements made by the previous speakers. He still believed that Erb's observations were extremely well founded and held good in the majority of cases. It was certainly true that if the faradaic response—in the case of facial paralysis, for instance—was never lost, in nine cases out of ten recovery would be more prompt than where it was lost. That the faradaic irritability returned in some cases before the power, as maintained by Dr. Leszynsky, was, he thought, exceptional, to say the least. It was much more certain that the power returned long before the faradaic response did in the vast majority of cases.

As regarded the value of electricity as a means of prognosis in cases of muscular dystrophy, the speaker thought it was very slight. The senses of sight and touch would teach us much more than the electrical examination in such cases. By the degree of response to the faradaic and galvanic currents we could get some idea as to the condition of each individual muscle, but no definite conclusions could be drawn. In some cases of typical muscular dystrophy certain muscles unquestionably did recover; others did not. In the cases where the muscles did recover, the electrical reactions did not undergo any decided changes.

Dr. A. D. Rockwell said he agreed with Dr. Sachs that the main importance of electricity as an aid to diagnosis was in connection with the absence or presence of the faradaic reaction. The importance of this subject to the general practitioner had been impressed on his mind by a case that had recently come under his observation. The case was one of facial paralysis, and the patient had been under the care of a general practitioner who had treated him with the faradaic current for seven weeks without any benefit. Under the use of galvanism the patient at once began to improve. The following case in-

dicated very positively the value of electricity as a diagnostic agent: The case was one of typical facial palsy on the right side, from peripheral causes. During the course of the patient's recovery from this, a paralysis occurred on the left side of the face; this started as a peripheral paralysis, but on testing the muscles with faradaism, it was found that they responded with perfect facility. Therefore it was evident that the paralysis on this side was central. Shortly afterward the patient had a second attack involving the right side of the face, again peripheral. Dr. Rockwell said that in ovarian or uterine diseases of an inflammatory character, the faradaic current produced no improvement, but rather aggravated the pain, while in non-inflammatory conditions the faradaic current would relieve the pain.

Dr. George W. Jacoby said that the statements made in the text-books on this subject were too dogmatic. The diagnostic value of electricity was limited to certain peripheral affections, and even there it was not so great as originally maintained. In prognosis, also, we must limit its value. In a number of cases of facial paralysis of long standing he had found it impossible to obtain any reaction of degeneration. In two other cases, in which the paralysis had entirely disappeared, with the exception of a slight obliteration of the labionasal fold, there had been marked reaction of degeneration. These were exceptional cases and he could give no explanation of them. Cases have been published in which there had been a reaction of degeneration found in cerebral palsies; also in cases of primary dystrophy.

Dr. C. A. HERTER referred to the electrical reactions in some cases of cerebral palsies. In one case under his observation, the patient, a woman aged seventy years, had a series of slight apoplectic attacks, succeeded in time by complete paralysis of the right side of the body-face, arm, and leg-and complete motor aphasia; at the end of a week distinct atrophy of the muscles of the forearm was noticeable, and at the end of a month it was very pronounced. The faradaic irritability of certain muscles of the forearm was very much reduced. The contractions were exceedingly sluggish, and the reaction of degeneration was undoubtedly present. The galvanic irritability of these muscles was somewhat diminished. Dr. Herter also referred to the rapidity with which the reaction degeneration made its appearance in some cases of injury to the spinal cord. In two instances under his observation it had been pronounced at the end of four days.

Dr. L. STIEGLITZ agreed with Dr. Sachs that the most important feature of the reaction of degeneration was the sluggishness of the contraction. It must be borne in mind that muscles of coarse fiber reacted much more sluggishly than those made up of fine fibers.

Dr. G. M. Hammond agreed in the main with the statements made by the previous speakers. Like Dr. Sachs, he had noticed that muscles which did not respond to a rapidly interrupted faradaic current would respond to a slowly interrupted one. The reverse was true with the galvanic current. With a battery that he employed he could get about 170,000 interruptions a minute, and he had found that the greater the number of interruptions the stronger the current required. This rule applied to both healthy and diseased conditions.

The PRESIDENT narrated the history of a case of facial paralysis that had come under his care. An examination showed increased contractility to galvanism in the muscles, and perfect preservation to faradaism, especially at the cathode. On the strength of this he had given a favorable prognosis. After six weeks of careful treatment the reactions had remained about the same, but the paralysis was no better. The patient then went to another neurologist, who made a like favorable prog-

nosis, and applied electricity with equally unfavorable results. That was now a year and a half ago; the reactions were still normal, but the face remained just as much paralyzed as before. (The discussion was continued at the next meeting. [See page 377].)

Dr. Dana exhibited a portable perimeter which he had devised. It was made by Meyrowitz & Co., of New York.

Meeting of March 6, 1894.

The President, Dr. M. ALLEN STARR, in the Chair.

Exophthalmic Goitre; Thyreoidectomy.—Dr. J. ARTHUR BOOTH presented the case of a woman, aged twenty-four years and single. The family and personal histories were negative. About two years ago the woman had first noticed an enlargement of the throat, and three months later the eyes had become affected. The patient was positive that there had been no heart symptoms until six months ago, when palpitation, throbbing in the vessels of the neck, shortness of breath, and flushing of the face had appeared. All these symptoms had gradually increased in severity, and the patient had become irritable, easily excited. anxious, and unable to sleep because of the tumultuous action of the heart. When the woman first came under observation both the eyes were very prominent, especially the left, and the lids did not follow the movements of the eyeballs (Graefe's symptom). The pupils were moderately dilated, reacting to light and accommodation. The fundus was normal and vision was not impaired. The enlargement of the thyreoid body was marked, the right lobe being the larger. The pulse was 150, of high tension; the apex beat of the heart diffused, but there was no murmur. The respirations were 24. There was no tremor of the hands or fingers. Examination of the urine was negative. The patient had been given daily applications of galvanism, and had received one two-hundredth of a grain of aconitine twice daily and fifteen grains of iodide of potassium three times daily. She had also been instructed to practice full inspiration frequently, and to rest as much as possible during the day. Under this treatment there had been decided improvement in the symptoms, but only temporary in character, and on November 8, 1893, thyreoidectomy had been performed by Dr. B. F. Curtis at St. Luke's Hospital, the right lobe of the thyreoid being removed. The patient had made an uneventful recovery, and during the four months that had elapsed since the operation there had been a decided improvement in all her symptoms. The pulse-rate now ranged between 96 and 110. Many of her nervous symptoms had entirely disappeared. She slept well, did not suffer from palpitation, and was able to attend to her housework. The eyeballs were much less prominent. The left side of the thyreoid had diminished in size to a slight extent since the operation.

Dr. Robert Safford Newton presented a case. The patient was a girl aged twelve years. In this case almost complete extirpation of the thyreoid had been performed, only a small supernumerary lobe being left. Since the operation the exophthalmia, which had been very pronounced, had almost entirely disappeared. Before the operation the pulse-rate had been 180, and the child had suffered from cyanosis. The systolic and diastolic heart-sounds had been almost synchronous. The operation had been 'performed by Dr. Fowler on October 21, 1893, and the child was out of bed three days afterward. Her pulse now averaged about 100. She was able to attend school, and was much improved in every way.

The President stated that the absolute contrast between the symptoms in exophthalmic goitre and myxedema made it seem very probable that many of the symptoms of the former disease were due to an excessive secretion of the thyreoid gland, just as those in myxedema were due to its suppression. Up to the present time there were not enough cases on record to permit us to make definite statements regarding it.

Progressive Muscular Atrophy of the Peroneal Type.— Dr. GEOEGE W. JACOBY presented the case of an illegitimate child, a girl, aged twelve years. The mother stated that the child's father was a large, well-proportioned man, but that he had been rejected for military service abroad because his muscles were weak. This had been the only hereditary factor obtainable. The history of the case, in brief, was as follows: There had been no trouble at the child's birth. When she was two years of age, some months after an attack of measles, she had complained of pain in the lower extremities, which was so severe that she could not stand. This had lasted about six weeks, and from that time on she had appeared to have difficulty in walking. She had always been able to move her legs in every direction. When she was four years old it was noticed that one leg was weaker and thinner than the other. About a year ago it was first noticed that there was an atrophy of the thigh on the side opposite to that of the affected leg. She held the legs in a stiff and clumsy position, and there was a lack of symmetry between the two buttocks. She had marked lordosis and a slight lateral curvature. The muscles of both thighs were in a continual state of unrest, almost like fibrillary twitchings. The right foot was in equino-varus position. There were no sensory disturbances. There was partial reaction of degeneration in the affected muscles. The arms were not affected. The superficial reflexes were normal. The tendon reflexes were present, but somewhat reduced on the affected side. Dr. Jacoby said that, while he regarded the case as one of progressive muscular atrophy of the peroneal type, it was not an absolutely typical one, inasmuch as the atrophy, although bilateral, was asymmetrical, one leg and the opposite thigh being affected.

Dr. B. Sachs agreed in Dr. Jacoby's diagnosis. The atypical distribution of the atrophy should not militate against the diagnosis, as that was really the last thing to be considered, although still so much insisted on by many writers. The distribution of the atrophy was largely a matter of chance. He had seen six cases of progressive muscular atrophy of the peroneal type, which was, perhaps, the rarest form of the disease. In none of these had there been a crossed distribution of the atrophy, as in Dr. Jacoby's case.

Hysteria with Peculiar Epileptoid Attacks.—Dr. BOOTH related the case of a man aged twenty-two years. He was a jeweler and a native of Germany. During the past two months he had had attacks in which he suddenly began to sing, to slap his knees with his hands (either one or both), and to stamp with his feet. The attacks came on without apparent cause, and occurred frequently during the day and occasionally at night. Each attack lasted only a few seconds and ended with a screech. The patient did not lose consciousness. When he was eight years old he had had similar attacks, extending over a period of nine months. Again, three years ago, he had them for a period of about a year. At that time he had undergone treatment at Strassburg, Germany, but had received no benefit. The attacks had ceased of themselves. The patient did not smoke, and drank moderately. He had practiced masturbation to some extent when he was younger, and had continued it for three years. His family history was negative. He had never had a blow or a fall. He denied venereal disease.

Neuralgia of the Great Occipital Nerve, associated with Symptoms of a Destructive Lesion of the Cervical Sympathetic.—Dr. ALEMANDER B. JOHNSON related the case of a man aged sixty years. He was married and a railroad conductor by occupation. He denied venereal disease and had no alcoholic habit. He had had malarial disease thirty years ago.

There was no distinct history of rheumatism and there were no signs of organic disease. Over the chest and back he had several old, white, depressed scars, which he stated were the result of abscesses he had had many years ago, which had been a long time in healing. The patient had presented himself on November 1, 1893, complaining of a severe pain in the right side of the head, which made it impossible for him to work. This trouble began three years ago. The pain was of an aching character and occurred in paroxysms. It was referred to a point about two inches behind the lobule of the right ear, and radiated upward and backward to the vertex. There was marked tenderness on pressure over this area. The patient further complained of inability to see well with the right eye, and the upper eyelid on that side drooped so far as nearly to cover the pupil when the patient looked straight before him; the lower eyelid was slightly elevated. The right pupil was contracted, smaller than the left, and did not react to light. The eye was watery and the right side of the face was redder than the left. There was no paralysis of the face, but the skin and muscles appeared less full and felt flabby in comparison with the left side. The patient had been examined by Dr. M. Allen Starr, who had located the lesion in the cervical sympathetic, and had advised an exploratory operation, as the patient had undergone medical treatment of various kinds without relief.

On November 4, 1893, an incision three inches and a half in length had been made along the posterior border of the right sterno-cleido-mastoid, beginning just below the mastoid process. The sterno-cleido-mastoid muscle and the internal jugular vein were drawn forward and the internal carotid artery was lifted up. The superior cervical ganglion was found to be included within the sheath of the internal carotid, to which it appeared to be distinctly adherent. The adhesions were divided and the ganglion was freed, as well as the cord below, to the extent of two inches. No abnormity in appearance could be recognized in either the ganglion or the cord, and the wound was closed. The neuralgic pains and the tenderness of the scalp had disappeared at once after the operation. The lacrymation and flushing of the face had ceased. The pupil on the right side reacted slightly to light and became a little larger, and the right upper eyelid drooped so little that the drooping was scarcely noticeable and did not at all interfere with vision. At the end of six weeks, however, all the symptoms had returned, and at the present time the patient found himself in no way improved.

Dr. Johnson said that, while the symptoms in this case were fairly typical of paralysis or a destructive lesion of the cervical sympathetic, it was possible that they were due to a lesion of a destructive character in the spinal cord, the exact situation of which it was at present impossible to determine. He was unable to explain the immediate temporary benefit of the operation in this case, except that it was the result of a powerful peripheral impression.

Dr. WILLIAM M. LESZYNSKY referred to a case which he had presented some years before, in which there had been hæmorrhage into the cervical portion of the cord, with decided symptoms of involvement of the cervical sympathetic on the same side.

The President said that Krause (Zeitschrift für Idinische Medicin, 1891) had reported nine cases of crushing accidents to the spinal cord, involving the lower cervical and upper dorsal segments, in which there were marked symptoms referable to the cervical sympathetic. Regarding the case narrated by Dr. Johnson, the president said his own impression was rather against the idea of a cord lesion, on account of the absence of other cord symptoms, although that was not a valid reason for excluding it entirely.

Electrical Reactions and their Value in Diagnosis and Prognosis. – The PRESIDENT stated that the subject of electrical reactions, and their value in diagnosis and prognosis, which had been taken up at the last meeting (see page 375), was such an important one that it had been decided to continue it at this time.

Dr. FREDERICK PETERSON said that in the main he agreed with the previous speakers regarding the reaction of degeneration, and to the conclusions recently published by Remak, in particular. We had found that both nerves and muscles might respond to both the faradaic and galvanic currents, and yet degeneration might exist. With the galvanic current, polar changes were inconstant; CCC might be greater than AnCC. In normal muscles we occasionally found, on the other hand, that AnCC might be greater than CCC. There was one sign that might be considered as always present where there was degeneration in the spino-muscular portion of the motor tract, and that was the sluggish, vermicular contraction of the muscle. Furthermore, in the great majority of cases of degenerative lesions in the anterior horns of the peripheral nerves, the faradaic reactions were diminished or lost. Dr. Peterson felt that sufficient stress had not been laid upon the actual value of electro-diagnosis in distinguishing cerebral palsies from the degenerative cases. He was convinced that most neurologists found it of the same value as heretofore, though we had modified our opinions as to the manifestations.

One of the speakers at the last meeting had called attention to the occasional occurrence of atrophy with degenerative reactions in cerebral palsies, as cited in two cases by Eisenlohr some years ago. It was interesting to know that Eisenlohr had recently made autopsies in both of these cases, and had found degeneration in the peripheral nerves. Other observers had found atrophic changes in the ganglion cells of the anterior horns in cases of hemiplegia with muscular atrophy. There was no evidence in those rare instances in which muscular atrophy accompanies cerebral palsy that the trophic change was produced by an affection of the trophic centers in the brain. On the contrary, all the evidence at hand showed that the atrophy depended upon degenerative lesions in the spinomuscular portion of the motor tract. The value of the electrical examination remained, therefore, as before.

The electrical reactions were certainly of great value in the distinction of the primary muscular dystrophies from progressive spinal atrophies.

Dr. J. F. Terriberry continued the discussion, and confined his remarks to the value of electrical reactions as regarded diagnosis and prognosis in paralysis of the facial nerve, and gave the following conclusions, which he had deduced from an analysis of twenty-four such cases that had come under his observation:

1. We have in electricity an agent of the highest value as an aid to diagnosis in paretic troubles of the seventh nerve.

The value of electricity as an aid to prognosis in facial paralysis is comparatively slight. Less than one half of the cases reported can be prognosticated, and even those with considerable hesitation.

Those cases in which the degree of paralysis is slight are the ones of which we can speak with most confidence by the aid of electricity.

4. It is impossible to foretell the issue of severe cases by means of the electrical examination.

5. The teachings of Erb respecting the diagnosis and prognosis of lesions of the motor peripheral nerves by means of electricity are the best at our command, although very imperfect.

Dr. William J. Morton sent a communication on the subject of electrical reactions, which was read by the secretary.

He stated that in case of degeneration of a nerve, the faradaic and galvanic excitability was diminished or lost, while in case of degeneration of a muscle the faradaic excitability was lost, but there was an exaggeration of the galvanic excitability, with an inversion of its normal polar action. This abnormal reaction of an abnormal muscle was indeed a most brilliant discovery by Erb, but it had always seemed to him that an over-refinement of diagnostic and prognostic significance had been attached to it. As regarded diagnosis, the electric reaction was often the only means of deciding that a given nerve or muscle was in process of degeneration. In traumatic neuritis, in multiple neuritis, in the sciatic, facial, and many other forms of neuritis, and in the dystrophies and spinal lesions due to affection of the nerve cells of the anterior cornu, it was certainly a great satisfaction to feel sure that the degenerative process existed, and this satisfactory result was easily acquired by aid of the electrical reactions. He did not, however, consider the reactions of much value in making a diagnosis between one and another of the affections mentioned, or between a multiple and a migrating neuritis, or between subacute or chronic anterior poliomyelitis and progressive muscular atrophy, or, lastly, between a cerebral and a spinal lesion. As regarded the prognostic value of electrical reactions. Dr. Morton believed that over-confidence was placed in the deductions to be drawn from the "complete" and the "incomplete reaction of degeneration" When it was complete, as we sometimes saw it in grave facial paralysis and in infantile spinal paralysis, the prognosis was unmistakably bad and fairly exact. It was in the incomplete reaction of degeneration that we were often proved to be mistaken if we indulged in a too exact prognosis. In cases where the electrical reactions of both nerve and muscle had been completely lost, he had known the muscle to regain some part of its former volume and the normal electrical reactions to return by means of long-continued local treatment with sparks from an influence machine. He considered that the earliest sign of reaction of degeneration was the failure of a muscle to respond to a spark which would set a corresponding normal muscle into contraction.

Dr. Leszynsky said that in making the diagnosis between peripheral and cerebral lesions in cases of facial paralysis, the quantitative changes should be taken into consideration. In the peripheral cases there was a quantitative diminution, while in the cerebral cases there was a quantitative increase. In paretic conditions he still relied on electricity, as regarded both diagnosis and prognosis. There were cases in which we made mistakes, but in the vast majority of instances the laws laid down by Erb were correct.

Dr. Sachs said that if the discussion of this subject at the last meeting had had a nihilistic tendency, it was due to the fact that it had been treated from the neurologist's point of view, and the speakers had attempted to make out in what way the current would be of value in refinements of diagnosis. He expressed the view that everybody still recognized the vast importance of electricity in the diagnosis between cerebral and peripheral cases or between cerebral and spinal cases, and also its great value in functional cases.

Dr. E. D. FISHER said that in the main he agreed to the statements made by the previous speakers. In certain diseases, such as the dystrophies, chronic anterior poliomyclitis, and progressive muscular atrophy, the electrical reactions were of great value. It was true that in the dystrophies there was not an absolute loss of the faradaic response until very late in the disease; with marked atrophy there might still be a response to the faradaic current wherever the fibers remained. As regarded the diagnosis between progressive muscular atrophy and chronic poliomyclitis, in the former there was not, as a rule, a complete

reaction of degeneration—there might be a partial one—while in the latter there was very apt to be complete reaction of degeneration. In distinguishing between cerebral and spinal lesions, electricity was of value, although not always essential.

## Miscellany.

A Bill to Establish a Bureau of Public Health within the Department of the Interior of the United States.—A new bill thus entitled, prepared by the National Quarantine Committee of the New York Academy of Medicine, reads as follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That there shall be established in the Department of the Interior, under the direction and supervision of the Secretary thereof, a National Bureau of Public Health to consist of a commissioner of public health and an advisory council.

That the duties of the Bureau of Public Health shall be to collect and diffuse information upon matters affecting the public health, including statistics of sickness and mortality in the several States, the investigation by experimental and other methods of the causes and means of prevention of disease, the collection of information with regard to the prevalence of contagious and epidemic diseases both in this and other countries; the publication of the information thus obtained in a weekly bulletin; the preparation of rules and regulations for securing the best sanitary condition of vessels from foreign ports, and for the prevention of the introduction of infectious diseases into the United States and their spread from one State into another, which rules, when approved by the President of the United States, shall have the force of law; the ascertaining by a suitable system of inspection that these rules and regulations are properly carried out and enforced; the advising and informing the several departments of the government, and executives and health authorities of the several States on such questions as may be submitted by them to it, or whenever in the opinion of the bureau such advice and information may tend to the preservation and improvement of the public health, and in general to be the agent of the general government in taking such action as will most effectually protect and promote the health of the people of the United States.

The commissioner of public health shall be an expert sanitarian appointed by the President, by and with the consent of the Senate, and shall receive a salary of \$6,000 per annum. He shall preside at the meetings of the advisory council and shall be the responsible head and executive officer of the bureau.

The advisory council shall consist of one member from each State of the United States. Such member shall be a physician of good repute and standing and shall be appointed by the Governor of the State which he is to represent in the council. The compensation of the members of the advisory council, when actually engaged in the performance of their duties under this act, shall be their actual traveling expenses and five dollars per diem for subsistence. The duties of the members of the advisory council shall be to aid in the gathering of information concerning the sanitary condition and health regulations of their respective States, and to consult with and advise the commissioner of public health regarding affairs within the province of the Bureau of Public Health at the annual or at special meetings, or under any condition which may seem to them to call for their opinion or suggestion.

Sec. 2. As soon as practicable after the passage of this act, the advisory council shall meet, with the commissioner of public health, at Washington, at such time and place as may be designated by the Secretary of the Interior, to perfect its organization and to proceed to the performance of the duties specified in this act. The advisory council shall thereafter meet annually at Washington on the first Tuesday of October and at such times and places as the President of the United States may designate, and shall continue in session for a period of time not exceeding six days, unless a longer continuance is especially authorized by the President of the United States.

SEC. 3. That the commissioner of public health shall prepare such rules and regulations as are necessary to be observed by vessels at the port of departure and on the voyage, where such vessels sail from any foreign port or place to any port or place in the United States, to secure the best sanitary condition of such vessel, her cargo, passengers, and crew, to be published and communicated to and enforced by the consular officer of the United States, which rules and regulations, when approved by the President of the United States, shall have the force of law and shall be carried into effect under the direction of the Secretary of the Treasury. None of the penalties herein imposed shall attach to any vessel, or owner or officer thereof, until a copy of this act, with the rules and regulations made in pursuance thereof, has been posted up for ten days in the office of the consul or other consular officer of the United States, in the port from which said vessel sailed; and the certificate of such consul or consular officer over his official signature shall be competent evidence of such posting in any court of the United States.

SEC. 4. The commissioner of public health shall from time to time publish the rules and regulations made by him and approved by the President to be used and complied with by vessels in foreign ports for securing the best sanitary conditions of such vessels, their cargoes, passengers, and crew, before their departure from any port in the United States and in the course of the voyage, and all such rules and regulations shall be observed in the inspection of the same on the arrival thereof at any quarantine station at the port of destination, and for the disinfection and isolation of the same, and the treatment of cargo and passengers on board, so as to prevent the introduction of cholera, yellow fever, or other contagious or infectious diseases, and shall furnish copies to the Secretary of State and to the Secretary of the Treasury to be by them issued to the officers of their departments.

SEC. 5. That it shall be unlawful for any merchant ship or other vessel from any foreign port or place to enter any port of the United States except in accordance with the provisions of this act, and with such rules and regulations of State and municipal health authorities as may be made in pursuance of, or consistent with, this act; and any such vessel which shall enter, or attempt to enter a port of the United States in violation thereof, shall forfeit to the United States a sum, to be awarded at the discretion of the court, not exceeding \$5,000, which shall be a lien upon said vessel, to be recovered by proceedings in the proper district court of the United States. In all such proceedings the United States district attorney for such district shall appear on behalf of the United States; and all such proceedings shall be conducted in accordance with the rules and laws governing cases of seizure of vessels for violation of the revenue laws of the United States.

Sec. 6. That any vessel at any foreign port clearing for any port or place in the United States shall be required to obtain from the consul, vice-consul, or other consular officer of the United States at the port of departure, or from the medical officer, where such officer has been detailed for that purpose, a

bill of health in duplicate, in the form prescribed by the commissioner of public health, setting forth the sanitary history and condition of said vessel and that it has in all respects complied with the rules and regulations in such cases prescribed for securing the best sanitary condition of said vessel, its cargo, passengers, and crew; and said consular or medical officer is required, before granting such duplicate bill of health, to be satisfied that the matters and things stated therein are true; and for his services in that behalf he shall be entitled to demand and receive such fee as shall by lawful regulation be allowed, to be accounted for as required in other cases.

Sec. 7. The President, in his discretion, is authorized to detail any medical officer of the government to serve in the office of the consul at any foreign port for the purpose of furnishing information and making the inspection and giving the bills of health hereinbefore mentioned. Any vessel clearing and sailing from any such port without such bill of health and entering any port of the United States shall forfeit to the United States not more than \$5,000, the amount to be determined by the court, which shall be a lien on the same, to be recovered by proceedings in the proper district court of the United States. In all such proceedings the United States district attorney for such district shall appear on behalf of the United States; and all such proceedings shall be conducted in accordance with the rules and laws governing cases of seizures of vessels for violation of revenue laws of the United States.

SEC. 8. That it shall not be lawful for any vessel to enter any port of the United States to discharge its cargo, or land its passengers, except upon a certificate of the health officer at such quarantine station certifying that said rules and regulations have in all respects been observed and complied with, as well on his part as on the part of the said vessel and its master, in respect to the same and to its cargo, passengers, and crew; and the master of every such vessel shall produce and deliver to the collector of customs at said port of entry, together with the other papers of the vessel, the said bills of health required to be obtained at the port of departure, and the certificate herein required to be obtained from the health officer at the port of entry; and that the bills of health herein prescribed shall be considered as part of the ship's papers, and when duly certified to by the proper consular or other officer of the United States, over his official signature and seal, shall be accepted as evidence of the statements therein contained in any court of the United

SEC. 9. That the Secretary of the Treasury shall have authority to forbid entry of vessels from ports known or suspected to be infected with cholera, yellow fever, small-pox, or other declared quarantinable disease into all minor approaches to a port of entry or into any inlet or place within the jurisdiction of the United States not provided with a complete quarantine plant, in order to compel such vessels to be subjected to maritime sanitation at the quarantine station equipped for that purpose and located in the region in question.

SEC. 10. That on the arrival of an infected vessel at any port not provided with proper facilities for treatment of the same, the Secretary of the Treasury may remand said vessel, at its own expense, to the nearest national or other quarantine station where accommodations and appliances are provided for the necessary disinfection and treatment of the vessel, passengers, and cargo; and after treatment of any infected vessel at a national or quarantine station, and after certificate shall be given by the United States quarantine officer at said station that the vessel, cargo, and passengers are each and all free from infectious disease, or danger of conveying the same, said vessel shall be admitted to entry to any port of the United States named within the certificate. But at any ports where sufficient

quarantine provision has been made by the State or local authorities, the Secretary of the Treasury may direct vessels bound for such ports to undergo quarantine at said State or local station.

SEC. 11. That when cholera or yellow fever or other disease declared quarantinable shall be ascertained by the commissioner of public health to exist within any port or place within any one of the United States or Territories, or the District of Columbia, in such form as threatens its spread to other ports or places within other States or Territories or the District of Columbia, by means of vessels and vehicles engaged in the transportation of goods or passengers between two or more States, or States and Territories, and the District of Columbia, whether by land or water, the commissioner of public health shall form such rules and regulations as in his judgment may be necessary to prevent the spread thereof from one State or Territory to another or the District of Columbia, which rules and regulations, when approved by the President of the United States, shall have the force of law, and the commissioner of public health is further authorized to employ such inspectors or other persons as may be necessary to enforce the rules aforesaid; and may select suitable localities for establishing stations on rivers and other lines of inter-State commerce and travel by railroads. and may cause to be erected necessary temporary buildings for the disinfection of passengers, baggage, cargoes, vessels, and vehicles, and may enforce the rules and regulations relating thereto approved by the President of the United States as aforesaid; it shall be lawful for the commissioner of public health, with the approval of the Secretary of the Interior, to confer upon any local health officer or health board within or near the locality where his or its authority is exercised, power to enforce the provisions of this act, and any rules and regulations made in pursuance thereof, and any person who shall knowingly disobey or violate any order, rule, or regulation made pursuant to the authority herein conferred, shall be deemed guilty of a misdemeanor, punishable by a fine of not less than five hundred dollars, and by imprisonment for a period of not less than one year.

SEC. 12. That the commissioner of public health shall, under the direction of the Secretary of the Interior, co-operate with and aid State and municipal health authorities in the execution and enforcement of the rules and regulations of such authorities, and in the execution and enforcement of the rules and regulations made by the commissioner of public health and approved by the President of the United States to prevent the introduction of contagious or infectious diseases into the United States from foreign countries, and into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia; and all rules and regulations made by the commissioner of public health and approved by the President of the United States shall operate uniformly and in no manner discriminate against any port or place; and at such ports or places within the United States as have no quarantine regulations under State or municipal authority, and where such regulations are, in the opinion of the commissioner of public health, necessary to prevent the introduction of contagious or infectious diseases into the United States from foreign countries, or into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia, and at such ports and places within the United States where quarantine regulations exist under the authority of the State or municipality which, in the opinion of the commissioner of public health, are not sufficient to prevent the introduction of such diseases into the United States or into one State or Territory or the District of Columbia from another State or Territory or the District of Columbia, and when said rules and regulations have been

made and approved by the President of the United States, they shall be promulgated by the commissioner of public health and enforced by the sanitary authorities of the States and municipalities, where the State or municipal authorities will undertake to execute and enforce them; but if the State or municipal authorities shall fail or refuse to enforce said rules and regulations, the President shall execute and enforce the same and adopt such measures as in his judgment shall be necessary to prevent the introduction or spread of such disease, and may detail or appoint officers for that purpose.

Sec. 13. That whenever the proper authorities of a State shall surrender to the United States the use of the buildings and disinfecting apparatus of a State quarantine station, the commissioner of public health shall cause an examination thereof to be made by a competent person, or persons, and if the said station, buildings, and disinfecting apparatus be found adapted to the purposes of a quarantine, and the commissioner of public health approve of their use as such, the Secretary of the Treasury shall be authorized to receive them and to pay a reasonable compensation to the State for their use.

SEC. 14. That whenever the commissioner of public health shall certify to the President, and it shall appear to his satisfaction that, by reason of the existence of cholera or other infections or contagious disease in a foreign country, there is danger of the introduction of the same into the United States, and that notwithstanding the quarantine defense, this danger is so increased by the introduction of persons or property from such country, that a suspension of the right to introduce the same is demanded in the interest of the health, the President shall have the power to prohibit, in whole or in part, the introduction of persons and property from such countries or places as he shall designate, and for such period of time as he may deem necessary.

SEC. 15. That it shall be the duty of the commissioner of public health to obtain information of the sanitary condition of foreign ports and places from which contagious and infectious diseases are or may be imported into the United States, and to this end the consular officers of the United States, at such ports and places as shall be designated by the commissioner of public health, shall make to the commissioner of public health weekly reports of the sanitary condition of the ports and places at which they are respectively stationed, and that the reports, according to such forms as the commissioner of public health may prescribe, shall be promptly transmitted to the Bureau of Public Health; and the commissioner of public health shall also obtain, through all sources accessible, including State and municipal sanitary authorities throughout the United States, weekly reports of the sanitary condition of ports and places within the United States, and shall also, so far as he may be able, by means of the voluntary co-operation of the State and municipal authorities, of public associations, and private persons, procure information relating to the climatic and other conditions affecting the public health, the prevalence of epidemic, and other diseases; and statistics relating to marriages, births, and deaths.

SEC. 16. That the commissioner of public health shall prepare, publish, and transmit to the medical officers of the Army, Navy, and Marine Hospital service, to collectors of customs and State and municipal health officers and authorities, weekly abstracts of the consular and other sanitary reports and other such information as he may deem advisable or proper.

SEC. 17. The Bureau of Public Health may, with the approval of the Secretary of the Interior, make investigations both in the United States and, if necessary, in foreign countries, into the nature, origin, and prevention of contagious, epidemic, and other diseases, as well as the causes and condi-

tions of particular outbreaks of disease in the United States, and in general may make investigations concerning matters relating to public health, and may employ such experts and for such time and in such manner as the exigencies of the service may require. When requested by the commissioner of public bealth, and when the same can be done without prejudice to the public service, the President may detail officers from the several departments of the government for temporary duty to act under the direction of said bureau, to carry out the provisions of this act; and such officers shall receive no additional compensation except for actual and necessary expenses incurred in the performance of such duties.

[N. Y. MED. JOUR.,

Sec. 18. That the commissioner of public health shall make an annual report of the operations of the Bureau of Public Health to the Secretary of the Interior, who shall transmit the same to Congress, with such recommendations as he may deem important to the public interests; and said report, if ordered to be printed by Congress, shall be done under the direction of the bureau; and that all mail matter of whatever class relative to the Bureau of Public Health and its duties, and addressed to the bureau or its commissioner, and indorsed "Official Business, Bureau of Public Health," shall be transported free of postage; and if any person shall make use of such indorsement to avoid the payment of postage on his private letter, package, or other matter in the mail, the person so offending shall be guilty of a misdemeanor, and be subject to a fine of five hundred dollars, to be prosecuted in any court of competent jurisdiction

SEC. 19. That the Bureau of Public Health shall take such action by correspondence or conference as will tend most effectually to secure the co-operation of the State, municipal, and local boards of health in establishing and maintaining an efficient and accurate system of notification of the existence and progress of contagious and infections diseases in the United States, and said Bureau of Public Health shall also by co-operation with the proper health authorities of foreign nationalities and municipalities, endeavor to extend to the United States a reliable system of international notification of the existence and progress of cholera, yellow fever, and other diseases declared quarantinable.

SEC. 20. Upon the recommendation of the commissioner of public health, the Secretary of the Interior is authorized to appoint, for duty under the instructions of the commissioner, not to exceed six sanitary inspectors at a salary not to exceed \$1,800 per annum each; at least two of these inspectors shall be experts in quarantine matters, two shall be skilled bacteriologists, and one shall be an expert statistician. The commissioner of public health is authorized to employ one chief clerk at a salary of \$1,800, one clerk of class 3 at \$1,600, one clerk of class 2 at \$1,400, and six clerks at \$1,000 each per annum; also one messenger at \$840, and one watchman at \$720 per annum.

SEC. 21. The commissioner of public health shall annually submit to the Department of the Interior, or the President, for trausmission to Congress, estimates for the expense necessary to maintain properly the Bureau of Public Health for the ensuing year.

SEC. 22. That there shall be and hereby is, appropriated, out of moneys in the treasury not otherwise appropriated, the sum of seventy-five thousand dollars, and the million dollars already appropriated and known as the emergency fund to be expended by the President is hereby appropriated to be expended in the execution of the provisions of this act.

Sec. 23. That the act entitled "An act granting additional quarantine powers and imposing additional duties upon the Marine Hospital Service," approved February 15, 1893, and all

acts and parts of acts inconsistent with this act, be and the same are hereby repealed.

The American Surgical Association.—The annual meeting will be held in the lecture room of the medical department of the Columbian College, 1325 H Street, N. W., Washington, on May 29th, 30th, and 31st, and June 1st. The preliminary programme gives the following special subjects for discussion:

1. The Surgical Treatment of Empyema, by Dr. John Ashhurst, Jr., of Philadelphia. The summary of Dr. Ashhurst's paper is as follows: 1. No operation is justifiable unless the presence of pus is certain; unless thorough treatment by medicinal agents, blisters, etc., has failed; or unless the symptoms, dyspnæa, etc., are so urgent as to demand immediate relief. 2. The first operation should consist of simple aspiration, with antiseptic precautions. 3. When the fluid has partially reaccumulated, as it almost certainly will do if purulent, incision and drainage should be practiced. 4. Drainage is best effected by making two openings, one at the lowest point, and carrying a large drainage-tube through the cavity from one opening to the other. 5. Drainage should be supplemented by washing out the cavity with mild antiseptic fluids; when the lung has expanded and the discharge has nearly ceased, the tube should be shortened, the upper opening being allowed to heal, and the tube then being gradually withdrawn through the lower opening. 6. When the lung is so bound down by adhesions that it can not expand, resection of two or more ribs should be practiced (Estlander's operation, so called), in order to allow collapse of the chest wall and to promote healing by bringing the costal and visceral layers of the pleura into contact. 7. The more extensive operations of Schede and Tillmann, while probably justifiable in exceptional cases, are not to be recommended for general employment.

2. Methods of Teaching Surgery, by Dr. John S. Billings, of the Army, whose paper is thus summarized: Two classes of students. 1. Undergraduates. 2. Those wishing to make a special study of surgery. For the first class, work of teaching divided between professors of pathology, of surgery, and of clinical surgery, and demonstrators. What should be the relations between these and the teachers of gynæcology, orthopædic surgery, genito-urinary surgery, etc.? Methods of teaching. 1. Didactic lectures. 2. Recitations. 3. Demonstrations by means of manikins, cadavers, operations on animals, etc. 4. Clinical lectures to large classes. 5. Practical clinical instruction to small classes. How far should the didactic teaching be subordinated to clinical and demonstrative teaching? Relations of hospitals to clinical teaching. Instruction in history and literature of surgery. Provisions to be made for special students.

3. The Surgery of the Kidney, by Dr. Louis McLane Tiffany, of Baltimore, of whose paper the following is an index: The influence of disease of the kidney on general surgery. Nephritis. Pyelonephritis. Nephrolithiasis. Nephrectomy, partial and complete.

4. Methods of Controlling Hamorrhage in Amputation at the Shoulder, as Illustrated by Three Cases of Amputation at the Shoulder Joint and of the Entire Upper Extremity, by Dr. W. W. Keen, of Philadelphia, in which the following points will be treated of: Amputation at the shoulder joint with the use of Wyeth's pins. Amputation at the shoulder joint with preliminary ligation of the vessels in the interspace between the deltoid and the pectoral muscles. Resection of the clavicle and securing the vessels, followed by amputation of the entire upper extremity, including the clavicle and scapula.

Further papers will be read by Dr. Hunter McGuire, of Richmond, and Dr. Joseph Ransohoff, of Cincinnati.

The American Medical Association.—The committee of arrangements has secured Odd Fellows' Hall building, corner of Market and Seventh Streets, for the meeting beginning June 5, 1894.

Assembly Hall, for the general meeting, has a capacity of fifteen hundred; the twelve smaller halls, for section work, range in capacity from five hundred downward, with committee rooms adjacent.

The engagement includes three of these rooms on Monday for the accommodation of associate organizations, such as those of the editors, colleges, etc.

The banquet room, on the ground floor, sixty-five by ninety-five feet, will be devoted to exhibition purposes, for which it is admirably adapted, and has been secured for the entire week, that exhibitors may have Monday in which to place their goods and Saturday in which to remove them. Nearly half the space is already taken, and others who desire to make a display of their goods under the most auspicious circumstances ever presented on the Pacific Coast should lose no time in applying to the chairman for space.

Headquarters for the association have been located at the Palace Hotel, corner of Market and Montgomery Streets, only four blocks from the place of meeting. Here we have Marble Hall, thirty by forty feet, as a registration room, where work will begin on Monday, and Parlor A for committee work.

The following hotels, centrally situated and convenient to the place of meeting, have made special rates for members and their families, which will apply during the entire stay of the visitors, who should, upon registering, signify that they are in attendance upon the meeting of the association.

The rates are for single persons, and the variation depends upon the size, situation, and appurtenances of the rooms, whether single, en swite, with private bath, etc. Special arrangements will be made for families or parties on timely notice.

Some of the hotels do business upon the American plan only, some upon the European plan only, and some upon either plan, to suit guests.

Palace Hotel (headquarters), American plan (rooms and board), \$3.50 to \$5.50 a day; European plan (rooms only), \$1.50 to \$3.50 a day. Baldwin Hotel, American plan, \$3.50 to \$5 a day; European plan, \$1 to \$3 a day. California Hotel, American plan, \$3.50 and up a day; European plan, \$1.50 and up a day. Lick House, American plan, \$2.50 and up a day; European plan, \$1 and up a day. Russ House, American plan, \$2 to \$3.50 a day; European plan, \$0 cents to \$2 a day. Occidental Hotel, American plan (only), \$2.50 and up a day. Hotel Pleasonton, American plan (only), \$2.50 to \$5 a day. Grand Hotel, connected with the Palace by a glass-inclosed bridge across New Montgomery Street, European plan only, \$1 to \$2 a day.

In addition, there are many other hotels, boarding houses, lodging houses, and restaurants contiguous to the place of meeting.

Post-office Section K is located in the Palace Hotel, on the office floor, adjacent to the registration room, where members can receive all mail matter by having it so addressed.

The Section in Surgery and Anatomy proposes to devote a portion of its time to the systematic consideration of a few selected subjects upon which papers, each not occupying more than ten minutes, will be read. The topics and papers to be so presented are as follows: I. Malignant Growths: The Pathology of Malignant Growths, by Dr. E. Laplace, of Philadelphia; A Critique of the Sporozoan Theory of Malignant Neoplasms from a Micro-technical Standpoint, by Dr. A. P. Ohl-

macher, of Chicago; The Clinical Recognition of Malignancy in Tumors, by Dr. C. A. Wheaton, of St. Paul, and Dr. Henry W. Coe, of Portland, Oregon; The Necessity of Early Surgical Interference in Malignant Tumors, by Dr. R. A. McLean, of San Francisco; The Value of Caustics in Malignant Growths, by Dr. John Parmenter, of Buffalo; The Radical Cure of Malignant Tumors by Operation, by Dr. J. H. Wythe, of Oakland, Cal.; The Value of Inoculations with Septic or Toxic Agents in the Treatment of Malignant Neoplasms, by Dr. John A. Wyeth, of New York. II. Tubercular Disease of Joints: Early Symptoms and Diagnosis of Tubercular Joint Disease, by Dr. Emmet Rixford, of San Francisco, and Dr. A. B. Judson, of New York; The Conservative Treatment of Tubercular Joints, by Dr. R. H. Sayre, of New York, Dr. Harry M. Sherman, of San Francisco, and Dr. James E. Thompson, of Galveston; The Operative Treatment of Tubercular Joints, by Dr. Robert W. Lovett, of Boston; The Treatment of Tubercular Joints by Injections of Iodoform, by Dr. N. Senn, of Chicago: The Treatment of Tubercular Joints by Injections of Corrosive Sublimate, by Dr. R. H. Plummer, of San Francisco. III. Hernia: The Causation and Prevention of Hernia, by Dr. James T. Jelks, of Hot Springs, Ark., and Dr. C. M. Richter, of San Francisco; The Management of Reducible Hernia, by Dr. Emory Lanphear, of Kansas City, and Dr. C. M. Fenn, of San Diego; The Treatment of Irreducible Hernia, by Dr. James B. Eagleson, of Seattle; The Treatment of Strangulated Hernia, by Dr. Joseph Ransohoff, of Cincinnati; The Radical Cure of Hernia, by Dr. W. E. S. Davis, of Birmingham, Ala., and Dr. H. O. Marcy, of Boston. IV. Hæmorrhoids, Fistula, and Fissure: The Pathology and Symptomatology of Hæmor rhoids, Anal Fistula, and Anal Fissure, by Dr. J. M. Mathews, of Louisville, and Dr. David Powell, of Marysville, Cal.; The Treatment of Hæmorrhoids, by Dr. H. M. Bishop, of Los Angeles, and Dr. Charles B. Kelsey, of New York; The Treatment of Anal Fistula, by Dr. J. McF. Gaston, of Atlanta, and Dr. G. B. Somers, of San Francisco; The Treatment of Anal Fissure, by Dr. Thomas W. Huntington, of Sacramento, and Dr. Lewis H. Adler, Jr., of Philadelphia. V. Fractures: The Treatment of Fractures of the Lower End of the Humerus, by Dr. Oscar H. Allis, of Philadelphia; The Treatment of Fractures of the Lower End of the Radius, by Dr. P. T. Conner, of Cincinnati, and Dr. C. L. Bower, of Philadelphia; The Treatment of Fractures of the Neck of the Femur, by Dr. Bedford Brown, of Alexandria, Va.; The Treatment of Gunshot Fractures, by Dr. George A. Goodfellow, of Tucson, Arizona; The Treatment of Fractures of the Shaft of the Femur, by Dr. Llewellyn Eliot, of Washington; The Treatment of Open or Compound Fractures, by Dr. H. H. Mudd, of St. Louis, and Dr. John B. Hamilton, of Chicago. VI. Obstruction to Urination in the Male: The Effects of Obstruction in Urination upon the Bladder and Kidneys, by Dr. J. William White, of Philadelphia; The Diagnosis and Treatment of Enlargement of the Prostate Gland, by Dr. Hunter McGuire, of Richmond, and Dr. W. T. Belfield, of Chicago; The Symptoms and Treatment of Stone in the Bladder, by Dr. W. T. Briggs, of Nashville; The Symptoms and Treatment of Tumors of the Bladder, by Dr. John B. Deaver, of Philadelphia, and Dr. C. F. Buckley, of San Francisco; The Treatment of Stricture of the Urethra, by Dr. J. Rosenstirn, of San Francisco.

The Shelby County (Indiana) Medical Society.—The sixth annual meeting will be held in Blessing's Opera House, Shelbyville, on April 9th, under the presidency of Dr. J. M. Adams, in addition to whose address the programme will include the following subjects for discussion: Diphtheria, by Dr. E. S. Elder, of Indianapolis (to be discussed by Dr. I. N. Love,

of St. Louis, and Dr. Theodore Potter, of Indianapolis); The Early Diagnosis of Pulmonary Consumption, by Dr. E. F. Wells, of Chicago (to be discussed by Dr. A. C. Kimberlin, of Indianapolis, and Dr. G. T. McCoy, of Columbus); The Diagnosis and Treatment of Floating Kidney, by Dr. R. Harvey Reed, of Columbus, Ohio (to be discussed by Dr. W. N. Wishard, of Indianapolis, and Dr. W. O. Roberts, of Louisville); Vaginal Hysterectomy, by Dr. L. H. Dunning, of Indianapolis (to be discussed by Dr. L. S. McMurtry, of Louisville, Ky., and Dr. C. A. L. Reed, of Cincinnati); The Exhibition of Pus Tubes recently removed, by Dr. W. H. Wathen, of Louisville, Ky. (to be discussed by Dr. T. A. Reamy, of Cincinnati, and Dr. Joseph Eastman, of Indianapolis); An Additional Report of Cases of the New Operation of Ligation of the Broad Ligament for Uterine Fibroids, by Dr. Franklin H. Martin, of Chicago (to be discussed by Dr. E. Walker, of Evansville, and Dr. H. O. Pantzer, of Indianapolis); The County Medical Society, by Dr. J. C. Culbertson, of Cincinnati (to be discussed by Dr. O. W. Kemper, of Muncie, and Dr. A. W. Brayton, of Indianapolis); Nasal Reflexes, by Dr. J. A. Thompson, of Cincinnati (to be discussed by Dr. H. W. Loeb, of St. Louis, and Dr. L. C. Cline, of Indianapolis); The Treatment of Gunshot Wounds of the Chest, by Dr. A. C. Bernays, of St. Louis (to be discussed by Dr. P. S. Conner, of Cincinnati, and Dr. John B. Hamilton, of Chicago): The Modern Treatment of Suppurative Processes of the Middle Ear, by Dr. Max Thorner, of Cincinnati (to be discussed by Dr. J. Morrison Ray, of Louisville, and Dr. Daniel Thompson, of Indianapolis); Is the Usual Treatment of Postpartum Hæmorrhage Correct? by Dr. W. G. McFadden, of Shelbyville (to be discussed by Dr. G. S. Mitchell, of Cincinnati, and Dr. John Moffett, of Rushville); Penetrating Wounds of the Eyeball, by Dr. J. O. Stillson, of Indianapolis (to be discussed by Dr. D. S. Reynolds, of Louisville, and Dr. F. C. Heath, of Indianapolis); and Ophthalmia Neonatorum, by Dr. A. Blitz, of Indianapolis (to be discussed by Dr. J. E. Harper, of Chicago, and Dr. C. R. Holmes, of Cincinnati). Further papers will be read by Dr. Joseph Ransohoff and Dr. Rufus B. Hall, of Cincinnati.

The Association of American Physicians.—The pinth annual meeting will be held in Hall No. 2 of the Columbian University, corner of Fifteenth and H Streets, Washington, on May 29th, 30th, and 31st and June 1st, under the presidency of Dr. R. H. Fitz, of Boston, in addition to whose address the preliminary programme includes the following:

Some Researches in the Significance of Albumin and Casts, especially in those past Middle Life, by Dr. Frederick C. Shattuck, of Boston; Some of the Chemical and Bacteriological Characteristics of Milk, by Dr. Thomas M. Rotch, of Boston; The Chemical Products of the Anaerobic Putrefaction of Pancreatic and Hepatic Tissues, and their Effects upon the Tests for Morphine, by Dr. Victor C. Vaughan, of Ann Arbor, Mich.; The Effect of Various Metals on the Growth of Pathogenic Bacteria, by Dr. Meade Bolton, of Baltimore; Dr. S. C. Martin's Researches on the Bacteria of Vaccinia, by Dr. Harold C. Ernst, of Jamaica Plain, Mass.; Note on the Observation of Malarial Organisms in Connection with Typhoid Fever, by Dr. W. Gilman Thompson, of New York; Experiments in Artificial Melanosis, by Dr. George Dock, of Ann Arbor, Mich.; The Mild Character and Diminished Prevalence of Syphilis and the Infrequency of Visceral Syphilis, by Dr. John H. Musser, of Philadelphia; A Case of Osteomalacia, by Dr. George Dock, of Ann Arbor, Mich.; The Treatment of Typhoid Fever, by Dr. Samuel A. Fisk, of Denver; The Treatment of Certain Symptoms of Croupous Pneumonia, particularly in Adults, by Dr. Beverly Robinson, of New York; A Study of the Temperature in Cerebral Apoplexy, by Dr. Charles L. Dana, of New York; Traumatic Headache, by Dr. Charles F. Folsom, of Boston; Tetany in America, by Dr. J. P. Crozer Griffith, of Philadelphia; Clinical Report of Two Cases of Reynaud's Disease, by Dr. Frederick P. Henry, of Philadelphia; A Case of Mitral Stenosis, with Great Hypertrophy of the Right Ventricle: Death from Hæmoptysis, by Dr. A. McPhedran, of Toronto: Stomatitis Neurotica, by Dr. A. Jacobi, of New York; Nocturnal Pain in Dyspepsia, by Dr. Henry M. Lyman, of Chicago; Lead Palsy in Children, by Dr. Wharton Sinkler, of Philadelphia; and A Report on the Ukimate Results obtained on Experimental Eye Tuberculosis by Tuberculin Treatment and Preventive Inoculation, by Dr. E. L. Trudeau, of Saranac Lake, N. Y.

The Medical Equipment of Men-of-war.—In the Union médicale for February 20th there is an abstract of an article, published in the Archives de médecine navale, by Dr. Gazeau on the system of packing and transporting drugs now in use in the French navy. He compares it with that of the English navy, greatly to the disadvantage of the former.

The French men-of-war are divided into twelve classes, and for each class different numbers of receptacles are required to hold the ninety-two medicinal substances which constitute the apothecary's stock on board ship. The construction of these receptacles differs for every port, and is often changed at the same port for two successive deliveries. Hence arises the first inconvenience, that on every vessel, at each equipment for service, the arrangement of the medicine closets of the infirmary must be entirely changed, as the shelves of the compartments, having served once, are not considered available for further use. This work requires four or five days. A still greater inconvenience arises from the impossibility of preparing the drugs in advance, as they are different for each vessel according to its destination, whether for the coasts of France or for a long cruise, and the destination is not known until the ship is equipped for service.

The preparation of pharmaceutical materials at the present time requires not less than five or six days, owing to the new regulation which has been in force for about eighteen months, and provides for the adoption of a separate delivery of each article on the catalogue, and, in proportion as the naval force is increased, this necessitates the frequent renewal of the number of compartments provided for a man-of-war, which is six hundred and six for a vessel with a crew of four hundred men for a long voyage. This explains the time demanded for the packing and transporting of these drugs. In this fact, says M. Gazeau, lies a danger the gravity of which forces itself upon our notice, and everything, he adds, should be done to avert it.

The singular means employed for the transportation of these drugs are extremely primitive. Bottles and vessels of all shapes and sizes are propped up with seaweed, packages of compresses or bandages, and bales of linen, in large willow baskets, and jolted over the rough pavement of the arsenals in a handcart, exposed to the noonday sun, the dampness of fogs, dirt, dust, and, in the ship's boat, the spray.

The English system is altogether different, and is at once simple, easy, and rapid. The drugs intended for each vessel are carefully packed in chests made in three sizes, each containing the requisite quantity for a year, according to the number of men comprising the crew, and marked with the corresponding number, thus preventing any mistakes being made in their delivery. They always contain the same preparations, no matter what the destination or character of the vessel may be, and, at all times, can be prepared in advance, and are always ready for transportation, which is then a question of only a few hours and not days, as it is in the French navy. Owing to this system

tem, any changes to be made are accomplished with the greatest rapidity, and, if a defective chest is reported, it can at once be replaced with another. These chests take up very little space, are kept in order without trouble, and are accessible in time of war, and the constant moving of the bottles, which have to be carried back and forth from the infirmary in the hold, is avoided.

383

Dr. Gazeau has made a study of the methods employed in the naval services of other countries, particularly that of the English, and these studies have suggested to him a new plan which will doubtless be of great advantage to the French naval service.

The Prize of the Medical Society of the County of New York.—The committee on prize essays calls the attention of the members to the annual prize offered by it, together with the rules governing the award of the prize:

- 1. The prize shall consist of a gold medal, one hundred and fifty grammes in weight, which shall bear upon one side the seal of the society, and on the other the following: Awarded as the annual prize by the Medical Society of the County of New York to —— for an essay on ——.
- 2. The essays shall be handed to the committee on prize essays on or before the 1st of October in each year.
- 3. Each essay shall be accompanied by a sealed envelope containing the name and address of the author and bearing on the outside the motto which is inscribed upon the essay.
- The writer of each essay is expected to present his dissertation in a plain and distinct handwriting, and with the pages bound in book form.
- 5. Any clew by which the authorship of an essay is made known to the committee will debar such an essay from competition.
- 6. Other things being equal, preference will be given to essays which exhibit original work on the part of the author.
- 7. The society does not consider itself as approving the doctrines contained in any of the essays to which the prize may be adjudged; and, in case of publication of a successful essay, the author shall be considered bound to print the foregoing in connection therewith.
- 8. The selection of the subject upon which to write will be left open to the competitors, but will be restricted to the field of what are called the departments of medical study.
- The society will return to unsuccessful competitors their essays, if called for within six months after the award has been made.
- 10. The committee is empowered not to award a prize in case none of the essays are worthy thereof.
- 11. The prize is restricted to members of the Medical Society of the County of New York.
- 12. The society reserves to itself the right to require that the essay for which a prize is awarded shall be read before the society previous to being placed at the disposal of the author.

The committee consists of Dr. Joseph D. Bryant, Dr. Virgil P. Gibney, and Dr. Græme M. Hammond.

The Treatment of Severe Contusions of the Abdomen.—
The Journal des praticiens for February 28th contains the report of a communication presented by M. Gross at a meeting of the Société de médecine de Nancy on January 10th. These cases, says M. Gross, are very serious, owing to such complications as visceral rupture, stercoral effusion, and peritonitis or symptoms of strangulation. This danger imposes on the surgeon the necessity of not relying on expectant treatment; there should be a positive diagnosis, but that is so much the more difficult at the outset because the symptoms often fail to be appreciated at that time. In organic affections of the abdomen, expectant treatment.

ploratory laparotomy is not positively serious. In cases of abdominal contusions the risks are reduced to a minimum, but still exist preceding peritoneal symptoms. Evidently there should be no occasion to discuss the gravity of abdominal contusions with visceral lesions. The surgeon should interfere, and his chances of success will be in direct proportion to the promptness of his intervention. He should try to be exact in his diagnosis, and, in case of doubt, proceed to open the abdomen, as he would if the lesion was serious. The dangers of laparotomy practiced in this manner are to be considered slight.

Hepatic Colic without Calculi .- At a recent meeting of the Société nationale de médecine de Lyon, the proceedings of which are reported in the Lyon médical for February 18th, M. Lépine said that he did not believe in the old theory that there could not be hepatic colic without calculi or other foreign bodies in the biliary ducts. He believed that hepatic colic with all its attendant symptoms could be caused by a simple spasm without foreign bodies. He based his theory on the three following classes of evidence: 1. Clinical. He described the frequency of hepatic colic in hysterical persons as a consequence of emotion or of an annoyance, without calculi being discovered in the stools. He had seen repeated attacks of hepatic colic caused by the ingestion of certain foods. Each time these attacks had been accompanied by two successive periods, one of polyuria, the other of anuria. Moreover, there had been retraction of the epigastrium and general spasm. 2. Post-mortem findings. In 1892 the Revue de médecine had published an account of an autopsy of a jaundiced person who for several weeks had had colic. The ductus choledochus had been found stretched and contracted, but containing no calculi, only a little gravel. He had observed another case, analogous to this one, where the man had received a blow in the right hypochondrium. He had had jaundice, and dropsy of the bladder had called for tapping. At the autopsy there had been found a cicatricial stricture of the ductus choledochus from two to three centimetres in length, without complete obliteration, where the probe could still pass. Jaundice bad existed, nevertheless, and still existed at the time of death. It had been, then, certainly due to a spasm. 3. Experimental. Spasm of the lower part of the ductus choledochus could be produced in dogs. M. Doyon had thoroughly studied the reflexes which might cause contraction of the biliary ducts, and had shown that they might have their starting-point in the

The possibility must be admitted, then, of a prolonged spasm of the biliary ducts which might be accompanied with pains and every appearance of hepatic colic.

The Cleveland Medical Society.—At the last meeting, on March 9th, nearly three hundred physicians were present. The society had lately so amended and revised its constitution and by-laws that physicians could be admitted from all parts of northern Ohio, and, in response to the invitations sent out, thirty applications for non-resident membership were sent in at the first meeting. The society now numbers over two hundred resident members and is steadily growing.

Dr. Howard A. Kelly, of the Johns Hopkins University, Baltimore, read a paper entitled A Consideration of Intra-abdominal Pressure, with Practical Deductions applicable to Gynæcology. Ho was listened to with close attention, and the many practical points brought out were received with marked appreciation. His was the first of a series of papers to be read before the society during the year by prominent men from other cities.

Professor Kelly presented to the society a rare old book—a copy of the third edition of the work on anatomy published by

Vesalius in 1514—and also another published by Tulp, of Amsterdam, in 1716, entitled *The Century of Observations*.

These were given for a nucleus about which the society hopes to build a large medical library. Already several large and valuable private libraries have been offered, and the society waits only for a fireproof building in which to store its volumes.

One of the distinguished guests said: "I am glad I came, as I have never before been in such a local medical society meeting in my life. A sort of medical revival must have struck Cleveland. It equals a State society. I venture to predict that the enthusiasm shown is indicative of a great future for this society. There could not be a more beautiful place of meeting. The accumulation of a medical library takes more time than anything else. Books are donated rather than purchased, but I predict that a large medical library will be rapidly collected in this great and growing medical center."

He advised that we hold on to the many men throughout the State who claim the Cleveland colleges as their alma mater.

Dr. M. J. Parke read a paper on Hypnotism, and ex-Judge Ring opened the discussion by setting forth the medico-legal aspects, while Dr. Henry S. Upson followed with a carefully prepared statement from the medical standpoint.

On the following morning Dr. Kelly gave a clinic in Charity Hospital before an immense company of physicians. He first catheterized the ureters in a case of suspected nephrydrosis, illustrating in the clinic many things of which he had spoken the previous evening. The second case was one of retroversion in which he brought the uterus into slight anteversion by two sutures through the posterior uterine and anterior abdominal walls. His method of suturing the abdominal wound was much appreciated. He used three sets of sutures, and all were buried. The last set brings the skin together, but the sutures do not pierce the epithelial layer, and are arranged in semblance to the walls of Troy. The last operation was upon a pelvic absecs, which was opened and drained through the vagina.

The Shortcomings of Disinfection in Rouen.-La Normandie médicale for March 1st contains the report of a recent meeting of the Société de médecine de Rouen at which M. Bataille made the following communication: A child had been attacked with diphtheria and taken to the hospital, and the au. thorities had been notified that it was necessary to disinfect an apartment in a certain locality where two other children were still living. M. Bataille thought that the bedding, the mattresses, and all other objects that might have been contaminated would be sent to the disinfecting steam bath; but the authorities had contented themselves with spraying the walls of the apartment with a 1-to-1,000 solution of corrosive sublimate, a method of disinfection which he said was absolutely useless. M. Bataille had been all the more astonished at this fact, as there was a law ordering the employment of the disinfecting bath together with the spray. It was in this manner that disinfection had been practiced during the last epidemic of typhus fever, and was still practiced in all other districts of France where diphtheria had to be combated.

The Ohio State Medical Society will hold its forty-ninth annual meeting at Zanesville on the 16th, 17th, and 18th of May, under the presidency of Dr. N. P. Dandridge, of Cincinnati. The secretary, Dr. Thomas Hubbard, of Toledo, to whom we are indebted for this information, remarks that, inasunuch as this year's meeting of the American Medical Association is to be held on the Pacific Coast, much of the material ordinarily reserved for its special sections will be brought out at the meetings of State societies; hence he predicts that those meetings will be unusually successful.

### Rectures and Addresses.

### LECTURES ON THE DIAGNOSIS OF ABDOMINAL TUMORS.

By WILLIAM OSLER, M. D., PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY.

LECTURE III .- TUMORS OF THE LIVER.

LET me remind you of two anatomical points: First, that the liver extends entirely across the upper portion of the abdominal cavity, so that tumors may project to either side of the middle line in front, more rarely into the left

pleura behind; and secondly, that in women the organ is frequently so dislocated that a large part of the convexity is in contact with the anterior abdominal wall; moreover, the anterior margin may be irregular from the projection of tonguelike portions, to which special attention will be directed in considering tumors of the gall-bladder.

Tumors of the liver are common, and, as a rule, their nature is not difficult to recognize. I shall not here refer to the simple enlargements of the organ in hypertrophic cirrhosis, in amyloid and fatty degenerations, or to the cases of uniform increase in volume met with in cancer and abscess. I shall call your attention only to those in which a prominent

nature of which had to be decided.

The usual causes are cancer, abscess, syphilis, hydatids, and occasionally tuberculosis. The tumors in connection with the gall-bladder I shall consider separately. Under certain circumstances the liver itself may form a tumorlike structure. The cases which have come before me for diagnosis in the past twelve months are distributed as follows: The liver itself, one; abscess, four; syphilis, two; cancer, four.

I. TUMOR FORMED BY THE LIVER ITSELF .- I show you here a little patient (Case XXV) in the upper part of whose abdomen you can see, even from a distance, a prominent tumor, which pulsates actively at the rate of ninety per minute, lifting the skin in the epigastric region. This case has been under our care on and off for the past two years. She is thirteen years of age, and has an old mitral-valve lesion from rheumatism, with enormous enlargement of the heart. The apex beat is, as you see, far out in the sixth and seventh interspaces. The præcordia is very prominent, and there are signs indicating that the

pericardium is adherent. During the past eighteen months ascites has constantly recurred, so that she is now tapped once a week, yesterday for the seventy-first time. When the abdomen is distended nothing is noticed, but after the fluid is withdrawn this remarkable tumorlike mass appears in the epigastrium (Fig. 21). On palpation, it is smooth, with a rounded edge, descends with inspiration, and expands visibly; and under the fingers, during the cardiac systole, it can be traced to the right, where at about the nipple line it passes beneath the costal margin. As it pulsates there can be felt, particularly at these periods, a toand-fro peritoneal friction rub. The pulsation is expansile, and with the fingers of the left hand beneath the costal

Fig. 21.—Pulsating tumor in the epigastric region consisting of the rounded and contracted liver.

nodular mass or swelling-a tumor-was detected, and the margin in the nipple line, and the right hand over the prominent mass, the whole structure can be felt to expand with each contraction of the heart. The situation, the shape, and the character of the pulsation leave no doubt whatever that this is a pulsating liver, a not very uncommon condition in chronic mitral disease, when the tricuspid becomes insufficient and allows each systole of the right ventricle to be communicated through the right auricle directly to the column of blood in the hepatic veins. The deformity of the liver, its cakelike shape, and rounded edge are caused, I believe, by a perihepatitis, possibly a direct extension from the pericardium, associated with which there is a chronic proliferative peritonitis. The recurring ascites is due partly to the contraction of the liver by the perihepatitis, partly to the chronic peritonitis. A case with almost identical features was for a long time under my observation at the University Hospital, Philadelphia.

> In two other conditions-neither of which, however, has been before us this year-the liver itself may form a tumor and cause no little difficulty in diagnosis: first, the so-called floating liver, which is most commonly met with

in women (though sometimes met with in men, as in a recent case reported by Kreider, of Springfield, Ill.), and is a feature of enteroptosis; and, second, the cases of great shrinkage and deformity of the liver in syphilis, in which the whole organ may be converted into a cluster of irregular nodular masses, held together by fibrous tissue, a condition to which the term botryoid has been given from its resemblance to a bunch of grapes.

II. Abscess of the Liver .-- Unfortunately for the victims of this serious disease, a prominent tumor mass is only occasionally present. Of nine cases of abscess of the liver seen since the first of September of last year, of which seven were in the hospital (hospital numbers 5876, 6109, 6745, 7679, 7687, 7738, and 8001), four presented a prominent tumor, the nature of which came up for discussion.

Case XXVI, Abscess of the Liver; Prominent Tumor; Incision; Recovery .- Dr. X., aged sixty years, admitted September 6, 1892, complaining of weakness and of a painful tumor in the side. Family history good. The patient has been a healthy man and has had very few illnesses, the only severe one being typhoid fever, in 1863. The present trouble dates from April of this year, when he began to have pain in the right side, fever, and chilly sensations. The temperature sometimes rose to 103°, and he had a sense of distention and fullness in the right side, but there was no bulging, as at present. No spleen is not palpable; area of dullness not increased.

Fig. 22.-Abscess of the right lobe of the liver forming a prominent tumor (Case XXVI).

history can be obtained of any local disease in the gastrointestinal tract. He is positive that there had been no diarrhea. After a month, during the greater part of which time he was in bed, the fever disappeared, but the pain and fullness in the right side persisted. Toward the end of June he noticed that there was a prominence below the right costal

weight-from 250 to 185 pounds. Since June he has had at times slight fever, but no chills, and only occasional sweating. The bowels have been irregular, and he has had to take purgatives. There has never at any time been jaundice.

Present Condition .- Fairly well nourished, a little pale, but neither emaciated nor cachectic. Temperature last evening 101°; pulse 104, occasionally intermits. The radials are sclerotic. The tongue is red, not dry.

Abdomen.-A large tumor mass fills up the right half, and is strikingly prominent, as indicated in the figure from a photograph (Fig. 22). Below, it reaches the transverse umbilical line; above, it passes beneath the costal margin. To the left the swelling begins at the middle line. The skin over it is glossy and a little reddened. The respiratory movements of the abdomen are slight. On palpation, the entire right side above the transverse iliac line is occupied by a solid mass which is resistant except at the most prominent point, where it is soft and fluctuating. It is nowhere painful on pressure. Below, no definite sharp edge can be felt. Above, it is continuous with and not to be separated from the liver. Behind, it occupies the entire flank and can be felt on deep pressure below the eleventh rib. On bimanual palpation it is fixed, not mobile. Percussion gives a flat note everywhere over the tumor. Liver dullness begins at the seventh rib and is continuous with that of the tumor mass. In the parasternal line there is a slight resonance between the margin of the ribs and the tumor. The

> The cervical and inguinal glands are not enlarged. There is a soft systolic murmur at the apex: otherwise the examination of the thoracic organs is negative.

As doubt had been expressed by several physicians who had examined Dr. X. as to the nature of the tumor, an exploratory aspiration was made in the most prominent portion and a gravish-red pus withdrawn, which on examination contained much molecular débris, pus cells, fatty crystals, but no amorba.

On the 10th, under chloroform, Dr. Finney made an oblique incision over the tumor and opened a large abscess cavity in the liver, removing more than a litre of foulsmelling pus, darkish in color; on examination, no amœbæ were found. The walls of the abscess cavity, as felt by the finger, extended beyond the middle line and upward out of reach beneath the ribs. They were everywhere hard and firm. The patient reacted well after the operation; the temperature fell, and on the sixth day he was wheeling himself about the ward in a chair.

Patient left the hospital September 28th, and when last heard from, six months after the operation, remained

Case XXVII. Abscess of the Liver; Prominent Tumor in the Epigastrium .- Mr. W., merchant, aged fifty-four years, seen September 16, 1893, with Dr. Opie. Patient was a healthy man margin which has steadily increased. He has lost much in until July, 1892. Has had the ordinary diseases, and syphilis when a young man. Twenty or more years ago he had diarrhea for some time.

He dates his present illness from July, 1892, when without any vomiting or diarrhea he began to have pains in the abdomen, which persisted with great severity for about two weeks. At this time he could not straighten himself without very great pain. The abdomen was swollen; he had no jaundice. He improved somewhat and went away for about six weeks and gained a great deal in weight. In September, on his return, he again had the severe pain and oppression in breathing. He was at this time under the care of Dr. Opie and Dr. Chambers, who state that the liver was greatly enlarged. Abscess was suspected, and an operation was suggested but declined. The swelling was not so marked as it is at present. He does not appear to have had any chills, sweats, or indeed much fever. There never has been jaundice, and it was subsequently suggested that the enlargement of the liver was due to syphilitic disease. He lost a great deal of flesh during this illness-as much, he thinks, as fifty pounds. Throughout the early part of this year he was very much better and gained about twentyfive pounds in weight. He went away in March, but was not at all benefited by the change. He lost strength and flesh, and lately has had a great deal of dragging pain in the side, particularly if he attempts to lie on the left side. He has had no diarrhœa and no vomiting.

The patient is a large-framed man, with sallow complexion, looks ill, and is decidedly emaciated. He was sitting up; no swelling of the feet; conjunctive pale but not jaundiced. The pulse is 96, tension not increased; he has no fever.

The abdomen is enlarged and a prominent tumor fills the epigastric region and extends toward the left hypochondrium.

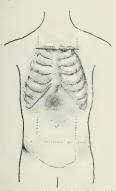

Fig. 23.—Outline of the liver and situation of the tumor in Case XXVII.

The skin over it is glistening, dry, and abraded from counterirritation. The superficial veins are not specially enlarged, except the left mammary, which is prominent. No enlargement of the superficial glands. On palpation, the abdomen is soft and natural until just at the level of the navel. Here the edge of the liver can be distinctly felt, To the left the edge passes obliquely and can be felt to pass under the costal margin at the ninth cartilage. To the right the edge passes obliquely upward and can be felt at the costal margin at about the tenth rib. Occupying the right epigastric region there is a prominent flat projection which causes a distinct

asymmetry in this region. It is not painful on pressure. It is soft and boggy, but there is no definite fluctuation. Percussion shows the liver dullness to be greatly increased. Above, it extends nearly to the lower margin of the fourth rib, crosses the sternum opposite the cartilage of the fifth rib, and is continuous with the cardiac dullness. There is a vertical liver dullness from the fourth interspace to the level of the navel in the parasternal line. Behind, the dullness reaches very high, almost to the angle of the scapula.

The spleen is not enlarged. The heart is a little pushed up; the sounds are clear. The examination of the lungs is negative.

The diagnosis of the condition was not at all easy. The progressive emaciation and the enormously enlarged liver and somewhat irregular outline suggested, of course, cancer, against

which, however, was the notable fact that he had improved so much after a very severe attack last year, in which the liver was enlarged. The prominent hemispherical mass in the right epigastric region was suggestive of abscess. Though he had had no chills and no fever, and although in the history not one of the usual ætiological factors preceding abscess of the liver was present, the sallow cachexia, the dragging pains on attempting to lie on the left side, and the prominent doughy tumor of the liver, made an exploratory examination advisable. An aspirator needle was thrust deeply into the most prominent part of the tumor and immediately a grayish and subsequently a reddish-brown pus flowed out freely.

The patient was removed to the City Hospital, where on September 21st Dr. Chambers opened the abscess and removed a gallon and a half of reddish, thin pus, which microscopically was made up of a granular  $d\ell bris$ , very few pus cells retaining their contour; no amæbæ. The patient rallied from the operation, but sank and died in about ten days.

Case XXVIII. Abscess of the Liver; Tumor in the Right Epigastric Region; Rupture into the Lung.—Simon G., aged twenty-seven years, admitted July 11, 1893, complaining of hiccough and pain below the ribs on the right side. He has always been healthy until five years ago, when he was laid up in the Hebrew Hospital for six weeks with a severe cough. His habits are good and he has not had venereal disease.

Three weeks ago his present illness began with irregular cramps in the hepatic region. He had hiccough for nearly a week, day and night, and this was in reality his most distressing symptom. He has vomited several times; lost his appetite and has only been able to take milk and whisky. The bowels have been constipated and he had never had any severe diarrhea. No cough; no expectoration. On July 1st he had a very severe chill in which he shook for an hour, followed by fever and sweating. The following day, July 2d, he felt better. On the 3d he had a second chill at eight o'clock in the morning, and shook for an hour. On the 4th he had another chill. He then went into the Norfolk Hospital, where he was given a great deal of quinine. He has sweated a good deal; has not noticed that he has become at all yellow. He has lost son ewhat in weight. At present he complains of the incessant hiccough and of pain in the region of the liver.

Present Condition.—Patient is fairly well nourished; face a little emaciated; conjunctive slightly tinged. The skin is not jaundiced. Tongue has a light white fur. Temperature has not been above 99.5° since his admission; pulse, 84; tension normal.

On inspection, the thorax on the right side looks a little fuller than the left, particularly behind in the infrascapular region. The left intercostal grooves are faintly visible; the right not at all. The apex beat of the heart is not visible; the percussion is clear on the left side; on the right side in front it is clear to the upper border of the sixth in the nipple line, and to the upper border of the fifth in the midaxillary line. Behind there is defective resonance at the angle of the scapula, shading quickly into dullness. The respiratory murmur is heard well on both sides. It is feeble in the infrascapular region on the right side; no râles; no friction. The abdomen looks natural, but there is a marked fullness on the right side in the hypochondriac region, and the groove below the costal margin is completely obliterated. In this region, occupying a space thirteen centimetres in diameter, there is a very definite prominence. On palpation, this is resistant and tender, and the skin at the costal edge seems a little infiltrated. The liver margin can be felt reaching nearly to the level of the navel and the edge is rounded. To the right it passes under the costal margin at the tip of the tenth rib. The left lobe can be felt filling the upper epigastric region. The liver dullness extends high in the axillary region, reaches the upper border of the fifth, and there is here eighteen centimetres of vertical dullness.

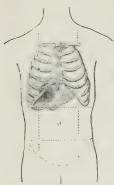

Fig. 24. Outline of the liver and situation of the tumor in Case XXVIII.

The edge of the spleen is distinctly palpable. The superficial lymph glands are not enlarged and the examination of the stomach and intestines is negative. A rectal tube was passed, but no amæbæ were tonnd in the mucus obtained. The blood examination was negative.

I aspirated in the parasternal line at the most prominent point of the tumor, but obtained no pus.

I did not see this patient again, but abstract the following from Dr. Thayer's notes: Although no pus was obtained on the first aspiration, there seemed to be no question as to the correctness of the diag-

nosis. Chills occurred on July 14th, 17th, 19th, and 23d, and on August 1st, 3d, and 4th. The patient was urged to have an operation, but declined. The tumor mass remained prominent, but no definite fluctuation developed. On August 20th the patient suddenly began to cough, calling for the nurse and saying that he felt something had burst inside him. He expectorated several spitcupfuls within a short time of a dirty, yellowish-green pus. The odor was not offensive; microscopically, it showed degenerated pus cells; no amobee. An interesting feature is that on the following day the prominence in the right epigastric region had almost disappeared. The physical signs at the right back had not changed. Over the area of dullness the respiratory murmur was simply enfeebled, and there were a few fine râles on coughing. The temperature range was from subnormal to 102°; once only, after a chill, 103.3°. He was repeatedly advised to have an operation, but declined, saying that he would sooner take his chances. The expectoration of purulent matter continued, but in diminishing quantities; thus on the 23d it was one hundred and twenty cubic centimetres; by the 26th, thirty cubic centimetres; and on the 28th, forty cubic centimetres. On August 1st it had fallen to only ten cubic centimetres; on the 3d he had none, and on the 6th only ten cubic centimetres. No amæbæ were found, only pus cells, most of them in a condition of disintegration. On August 8th he was taken home by his brother, the condition not having materially improved, and the temperature still ranging from 98° to 102°, occasionally to 103°. The prominent mass on the right side never reappeared. On discharge, the liver flatness began in the fifth interspace in the nipple line; the border could be felt five centimetres below the costal margin. In the midaxilla there were thirteen and a half centimetres of vertical dullness. In the median line from the upper limit of flatness to the lower border, determined by palpation, was fourteen centimetres.

Case XXIX. Acute Dysentery; Abscess of the Left Lobe of the Liver; Tumors in the Left Epigastric Region; Incision; Death.—Raphael F., tailor, aged twenty-seven years, admitted August 22, 1893. His family history is good. Patient is a Russian, and has been in this country only nine years. Has been always healtby and strong.

Present illness began abruptly about a month ago with an attack of vomiting and purging; had six or eight stools the

first day. The next day he was rather better and was pretty well for two or three days. Then he again had vomiting and much purging. Evidently the attack was one of acute dysentery, as he had numerous stools containing slime and blood, passed with much straining and tenesmus. He does not think he had at this time any fever. He has lived almost entirely on milk. The diarrhea has continued ever since. On admission, he was thin; lips and mucous membranes of good color; tongue covered with a thick, white coating. The temperature was 97°. The examination of the thoracic organs was negative. The abdomen was retracted; patient complained of pain on palpation over the excal region. The liver dullness began in the sixth interspace in the nipple line and extended to the costal border. The edge was not palpable. He had three stools within the first twenty-four hours, brownish in color, fluid, and containing small strings of mucus. In the mucus obtained by passing the rectal tube numbers of actively moving amæbæ were found. He was ordered large, high injections of sulphate of quinine-one to two thousand-and a milk diet. During the first week in hospital there was no special change. The passages were from four to seven in twenty-four hours. The temperature was never above 99°, and he seemed to be doing well. For the next two weeks also he seemed to be very comfortable. The temperature between August 29th and September 11th was not above normal. The dysenteric symptoms had improved very much, and from September 9th to the 13th he had only had one or two movements a day. On September 14th he made, for the first time, complaint of a pain in the epigastric region, and there had been for two days slight fever, the temperature rising to 100°. There was a little sensitiveness over the liver in the middle line, but the organ did not appear to be enlarged. On September 17th there was noticed for the first time a rounded prominence occupying the left half of the epigastric region, which moved up and down with respiration and which pulsated with each heart beat. It extended from the costal margin in the parasternal line to a little beyond the middle line. It was rounded, smooth, firm, but elastic, and did not appear to fluctuate. The pulsation was very marked

and seemed almost expansile. On placing the patient, however, in the knee-elbow position the pulsation entirely ceased; no bruit was heard over it. The situation of the tumor is indicated in the annexed diagram. The liver dullness began at the sixth rib and extended just below the costal margin in the nipple line. In the parasternal line it did not begin until the seventh rib, and in the middle line the dullness was about the middle of the ensiform cartilage and was then continuous with the tumor mass on the left side, In the midaxillary line the dullness began at the seventh rib and extended to the costal border. The splenic dullness

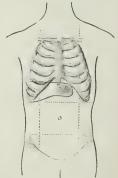

Fig. 25.—Outline of the liver and situation of the tumor in Case XXIX.

could not be obtained, nor could the margin be felt. There was no increase in the hepatic dullness behind.

On the 18th the temperature rose to 101.2°, the highest point reached, and the patient had no chills, but was sweating profusely. The tumor was more prominent; was very tender, but there were no signs of fluctuation. The diagnosis of abscess of the liver was made and the case was transferred to the surgical wards. Dr. Finney operated, found the peritonæum adherent to the liver, and opened a superficial abscess in the left lobe. About seventy-five cubic centimetres of thick, yellowishgreen pus were evacuated, in which amæbæ were present. The patient stood the operation very well, but he became progressively weaker. The temperature never rose above 101.5°. He died on the 24th.

The situation of the palpable tumor in liver abscess is well illustrated by these four patients. In Case XXVI it was in the right lumbar and right side of the umbilical regions, entirely below the costal margin. In Case XXVIII it was in the right hypochondriac region. In Case XXVIII it was median, projecting prominently midway between the navel and ensiform cartilage; and in Case XXIX it was entirely to the left of the middle line in the upper quadrant of the epigastric region.

In the diagnosis of liver abscess you must take into consideration the following points:

Antecedent Conditions.—Dysentery is in this latitude by far the most common, though it was only present in one of the four cases I have narrated. Of the nine cases, however, under observation during the past year, dysentery occurred in six cases. There may, however, be no recognizable cause, as in Cases XXVI, XXVII, and XXVIII. Bear in mind that when the patient comes before you with chills and fever, a sallow cachexia, and an enlarged, tender liver, the dysenteric symptoms may have entirely disappeared, or there may be only at intervals slight recurrences. Under these circumstances a catheter or the long rectal tube passed into the bowel may bring away portions of mucus containing the amæbæ, associated with the severer form of dysentery.

Toxic Features.—Irregular fever, chills, and sweats are rarely absent. The sallow tint of the skin, the progressive anaemia, and the paroxysms of intermittent fever lead very frequently to a diagnosis of malaria.

Local Symptoms.—Increase in the size of the liver and tenderness on pressure are the most important. The enlargement is most frequently of the right lobe, but the whole organ may be greatly increased in size and extend below the navel. When the abscess is in the right lobe the enlargement may be chiefly behind, ascending high into the right pleura. Prominent bulging of the lower portion of the right side of the thorax is extremely common.

And lastly, and what interests us here especially, a tumor mass may develop beneath the right costal margin or in the epigastric region. The tumor is usually (always when recent) tender; often develops with rapidity. The rapid increase in size with tenderness, however, is not to be relied on as characteristic, as I will mention to you in the fourth of the cases in the cancer series this was a very marked feature. Fluctuation may be obtained readily when the tumor mass becomes superficial. The tumor may persist, as in Case XXVI, for months without very much change. With or without the presence of tumor, when liver abscess is suspected, the long aspirator needle should be freely used.

#### (To be concluded.)

RECENT EXPERIMENTAL CONTRIBUTIONS TO THE PHYSIOLOGY OF DEGLUTITION.\*

By S. J. MELTZER, M. D.

When I accepted the courteous invitation of our chairman to read a physiological paper before this section I was prompted by the desire to bring to your notice a subject in which I was for a time personally intensely interested. I mean the results of a long series of experiments upon certain problems of the physiology of deglutition. I shall attempt to give a brief review of the facts and how they were found. I now enter without further apology on the discussion of our subject.

Deglutition is the act of conveying food or drink from the mouth into the stomach through a part of the alimentary canal where neither digestion nor absorption occur. Motion is, therefore, the only function which here comes into consideration, and as the entire deglutitory canal is sufficiently provided with muscular tissue, there seemed to be very little left to the physiology of deglutition besides a classification of the anatomy of the parts in question. Since Magendie, the entire complex of deglutition is usually divided into three acts: the muscles of and around the mouth convey food and drink into the pharynx, from where the pharyngeal muscles then transmit them further into the œsophagus. There the swallowed mass is carried down into the stomach by the so-called peristaltic movements of the œsophagus. According to this theory, then, the transmission of the bolus through the entire deglutitory canal is effected in each part by the muscle fibers located within it. This theory predominated until 1880, when Professor H. Kronecker made the observation that liquids reach the stomach too quickly after being swallowed to justify the belief that they are transported by the slow process described above. He then induced the late Professor F. Falk to investigate this question. The experiments they performed consisted in introducing into the pharynx a tube connected with a manometer, thus studying the pressure in the pharynx during the deglutition. The pressure was found to be as high as twenty centimetres water. Kronecker and Falk, t in reporting this experiment, have put up the hypothesis that the transmission of liquids and soft masses from the mouth into the stomach is not accomplished by the peristalsis of the asophagus, but the morsel is rather thrown down by a force located within the mouth or the pharynx. The experiments of Falk, however, have only demonstrated that there is during deglutition sufficient force in the pharynx or above it to accomplish such a throwing down of food. But they have by no means proved that the transmission of the food is really

<sup>\*</sup> Read before the Section in Neurology of the New York Academy of Medicine, February 16, 1894.

<sup>†</sup> Magendie. Thèse soutenue à l'École de médecine de Paris, 1808.

<sup>‡</sup> Falk and Kronecker. Ueber den Mechanismus der Schluckbewegung. Du Bois-Reymond's Archiv, 1880, p. 296.

accomplished by this force and not by the peristaltic movements.

When, by the advice of my friend and teacher Professor Kronecker, I started on further investigation of the mechanism of deglutition, my first task was to find an efficient method by means of which the point in question could be proved or disproved. I shall not venture to mention here all the attempts and methods employed to attain our purpose. I wish only to speak in detail of a method which not only solved our problem satisfactorily, but was also fruitful in disclosing many other valuable facts. It is simply the graphic method.

When the open end of a stomach tube is connected with a Marey's tambour, the lever of which writes on a revolving kymograph, while a small rubber balloon is attached around the opening of the other end of the tube, any pressure exerted upon this balloon will increase the pressure in the Marey's tambour and raise the lever, thus producing a curve upon the revolving drum. If the pressure is a short and quick one, the curve will appear short and steep; if the pressure is long and the increase and decrease are slow, then the curve will also be long and with a more gradual ascent and descent. Now, if the balloon end of the stomach tube is placed within the œsophagus, the balloon will be compressed either by the passing by of the food or by the contraction of the œsophagus, thus producing a characteristic curve upon the revolving kymograph. If, further, another shorter tube with a balloon is placed within the pharynx, while the other end is also connected with a Marey's tambour, the lever belonging to this tambour will write a characteristic curve of the pharynx. If we now add a time marking apparatus, and if the levers belonging to both tubes are adjusted in a vertical line one above the other, we are then enabled to measure the time which elapses between the beginning of the two curves—i. e., between the beginning of the contraction of the pharynx and the beginning of the contraction of the œsophagus.

I shall not mention all the difficulties which had to be overcome; it will be sufficient to state that I finally learned to place both tubes in my own pharynx and œsophagus and keep them there continually for hours while drinking liquids or swallowing soft food. The balloon end of the esophagus tube was shifted in different sections of the æsophagus, while the pharynx tube, of course, always remained in the same place in the pharynx. The curves which were produced by the esophagus tube always had two elevations: first came a short and steep one; then, after a certain interval, a prolonged elevation followed. The height of the steep elevation was always in proportion to the quantity of the swallowed mass; after an "empty" swallow the elevation was very low, while the prolonged elevation was entirely independent of the quantity swallowed. The size of this elevation depends upon the section of the œsophagus only in which the balloon was located, of which more later. It was unmistakably clear that the first elevation was produced by the rapid passing by of the food, while the second elevation was due to the contraction of the esophagus. The curve produced by the pharynx tube had also two elevations, or rather one eleva-

tion with two crests. The constant interval between these two crests amounted to three tenths of a second. It was apparent that in the pharynx curve also the first sharp crest was produced by the passage of food, while the other rather flat crest was due to the contraction of the pharyngeal muscles. The interval between the first point of the pharynx curve and the first sharp elevation of the œsophagus curve, no matter of what section, did not amount to more than one tenth of a second. These curves, then, teach us that the food is indeed thrown down from the mouth through the pharynx and œsophagus with great rapidity, not only before the peristaltic movements of the œsophagus appear, but even before the muscles of the pharynx commence to contract.

I shall mention here that the astonishing rapidity with which, according to these experiments, the swallowing of food takes place induced us to test it by still another kind of experiment.\* I shall not speak any further of these experiments, except to say that their outcome was a positive confirmation of our mentioned results.

I have just stated that our experiments demonstrate that the throwing down of food occurs even before the contraction of the pharyngeal muscles takes place. The throwing force, then, must lie in front of the pharynx muscles. Our next task was now to find the source of this forcei. e., to ascertain which of the muscles of the mouth accomplished this rapid swallowing. By previous experiments of Kronecker and Falk it had already been established that the deglutition was little impaired by the bisection of both hypoglossus nerves in animals. Thus the muscles of the tongue being excluded, my attention was turned toward the mylo-hyoid muscles. Indeed, after the bisection of the nerves leading to these muscles in a dog, this animal could not drink any more from a vessel standing on the floor. It will not be superfluous to remind you here of the anatomy of these muscles. The origin of these muscles is the mylohyoid ridge of the inner surface of the inferior maxilla, and their insertion is in the middle tendinous rhaphe common to both muscles. They form together a concave bed for the reception of the tongue, which by the contraction of these muscles is lifted up and pressed against the palate. This pressure ought to develop a considerable force, as the tongue, even in a state of rest, is in contact with the palate. The pressure is still more increased by the contraction and the thickening of the tongue itself which accompanies the beginning of the deglutition.

If we have only these parts in our mind—the concave bed of the mylo-hyoid muscles, covered on the top by the palate and terminating in the pharyngeal and œsophageal tube—we may well compare the entire canal to a bulb syringe, where a quick, strong pressure upon the bulb squirts the liquid with great rapidity through the attached tube.

I shall mention here briefly that dissection of the pharyngeal muscles in dogs did not prevent them from swallowing in a natural way, only that in some of the ani-

<sup>\*</sup> Meltzer. Ueber die Vorgänge beim Schlucken. Du Bois-Reymond's Archiv, 1880, p. 446.

<sup>†</sup> Meltzer. Die Bedeutung des Mylohyoideus. Du Bois-Reymond's Archiv, 1880, p. 299.

mals after a while "Schluckpneumonie" developed.\* This means that, though most of the food has been thrust by the mylo-hyoid muscles through the pharynx into the œsophagus, some of it occasionally remains within the pharynx, and, as the pharyngeal muscles have been cut, these remnants could not be removed by them into the œsophagus, and thus found their way into the larynx and the lungs.

Turning again to our graphic method, I have to state that the further experiments have been continued with the esophagus tube alone, taking the first steep elevation as the mark for the beginning of the deglutition; the difference of time, according to the statement made above, was not more than a tenth of a second, and could therefore be neglected. With this tube I obtained the characteristic curves of all the parts of the œsophagus, the studied localities being only two centimetres apart. The results were as follows: The interval between the first and second elevations was the longer, the deeper the balloon was pushed into the esophagus. But, instead of observing a steady and proportional increase in the interval with the depth in the esophagus, we found that, within the first section of six centimetres' length, the interval between both elevations remained the same, about a second and a fifth. Then came another section of twelve centimetres' length, where again the interval of the entire section was the same-i. e., about three seconds. Finally, a section of six centimetres followed, with a constant interval of about six seconds. 'This all means that the movements of a human œsophagus, at least of my esophagus, are not of a peristaltic nature; the contraction of the œsophagus occurs in three sections. The first section begins to contract a second and a fifth, the second section three seconds, and the last section six seconds after the beginning of deglutition. A similar result was obtained in the study of the duration of the contractions; each section had in its entire length an equal duration. The contraction of the first section of six centimetres' length lasted in all its parts about two seconds; in the second section of twelve centimetres' length the contraction lasted about five seconds; the duration of the contraction of the third section was from six to seven seconds. Thus the beginning of the contraction, as well as the end of it, occurs in each entire section simultaneously.

If we add to these three sections of the œsophagus the upper two sections of our canal—i.e., the mylo-hyoid and the other muscles of the mouth as the first and the pharynx as the second section—we may then state that the whole canal is divided into five sections. At the beginning the mylo-hyoid muscles contract and relax with great rapidity; then, three tenths of a second later, a somewhat prolonged contraction of the pharyngeal muscles follow. After an interval of nine tenths of a second the œsophagus commences to contract in its three sections, as stated above.

Another point of interest is the development of the contraction in each section. While the mylo hyoid muscles contract rapidly, we observe that in the following sections the development of the contraction to its maximum

\* Meltzer. Ueber die Vorgänge. Du Bois-Reymond's  $Archiv,\,1880,$ p. 447.

occurs the slower the longer the contraction lasts, or, what is the same here, the deeper the section is in the canal. And, as the thrusting power of a muscle depends on the quickness with which the contraction reaches its maximum, it follows that the deeper the section of our canal, the less its thrusting power.

I wish here to remind you that there is indeed somewhat of a basis in the anatomical structure of the human esophagus for the physiological differences just established in the several sections. The upper third of the esophagus, as is well known, contains only striated muscle fibers; the middle part contains striated as well as plain muscle fibers; while the muscular sheath of the lowest part is made up of plain muscle fibers only.

The whole theory now presents itself as follows: \* A fluid or soft morsel is usually thrown down by the contraction of the mylo-hyoid muscles through the entire length of the deglutitory canal, before the contractions of the other sections occur. The contractions of all the other sections follow, nevertheless, after each deglutition, in the manner described above. The value of these contractions is only that of a reserve power-i. e., if, for some reason, a part of the morsel remains in any of the sections, the contraction of this section will convey it further down. A dry bolus, however, can certainly not be thrown down, and its conveyance through the deglutitory canal probably, indeed, occurs by transmission from one section to the other. It should be remembered, however, that the food swallowed by human beings is usually in a semi-solid state, and a dry bolus forms the exception; while in animals whose food is usually very dry, like rabbits, for instance, the transportation by peristaltic movements of the œsophagus is probably the rule. But it is interesting to note that in these animals the thick muscular coat of the œsophagus consists exclusively of striated fibers, in accordance with which we here find that the peristaltic wave reaches the stomach already two seconds after the beginning of deglutition. This goes to show that the wandering of the food through the thoracic part of the alimentary tube has to occur quickly, and this is usually effected, according to the character of the food of the animal, either by throwing the food down through the œsophagus, or by a quick peristaltic movement of the latter, as a longer stay of a bolus within the thoracic cavity may interfere with the functions of the organs located therein.

To the five sections of the deglutitory canal we may now add the cardia. The movements of this latter section I have not, for various reasons, been able to study in my own coophagus. But in a rabbit this part is very well accessible to our observation, and there we have indeed seen how after each deglutition at the end of the peristaltic wave the cardia sets in with a characteristic motion; † at first a strong circular contraction appears, and immediately afterward a

<sup>†</sup> Meltzer. Ueber den Schluckaet und die Rolle der Kardia bei demselben. Verhandlungen der physiologischen Gesellschaft zu Berlin, 1881, p. 74. Du Bois-Reymond's Archiv, 1881.

deep diving of the entire cardia into the stomach follows. The entire phenomenon reminds one of the manipulations employed to press down the contents of a filled bag. In fact, the contractions of the cardia do not aid as much the transmission of the food from the æsophagus into the stomach as they serve to keep the passage into the stomach free from accumulation of the swallowed mass. I shall state here briefly that even at rest the cardia is in a state of tonic contraction.

While striving to find a plainer method by means of which at least our main results could be confirmed, I came to discover, \* or rather rediscover, † the sounds of deglutition heard in the stomach. When we put a stethoscope on the epigastrium at the left side of the ensiform cartilage, we hear in all normal persons, six or seven seconds after the beginning of a single deglutition, a wellmarked prolonged murmur or sound, as if fluid mixed with air is being pressed through the cardia. As six seconds after the beginning of deglutition is just the time when the last section of the œsophagus commences to contract, we may rightly entertain the view that the mentioned sound is due to the contraction of this section. In a few persons, however, a sound could be heard at the very beginning of the deglutition. This sound differs greatly in its character from the former sound. It makes the impression as if fluid were squirted into the stomach. I named both sounds according to their character: the first, press sound (Pressgeräusch); the other, squirt sound (Spritzgeräusch). The squirt sound was also called the first, and the press sound the second, because the one comes at the beginning, the other at the end of deglutition. In connection with these sounds of the stomach it shall be stated further that nearly simultaneous with the beginning of deglutition a sound can be heard at the left side of the spinal column, from the fifth cervical to the ninth dorsal vertebra. The presence of these sounds was discovered by Hamburger. † Now we have in the presence of these sounds a confirmation of at least two main points of our experimental results. The presence of a constant sound as deep as the ninth vertebra, at the very beginning of deglutition, proves that the morsel is indeed thrown down to the very end of the œsophagus at the very beginning of deglutition; while the constant presence of the press sound in the stomach about six seconds after the beginning of the deglutition indicates the constant sequence of the so-called peristaltic movement and its arrival in the last section of the œsophagus about six seconds after the beginning of deglutition. I shall not enter here into a further discussion of the meaning of the sounds in the stomach, as it is still a matter of controversy between ourselves and C. A. Ewald, which I intend to take up more fully at another opportunity.

We have stated above that after each deglutition the contraction of the œsophagus followed in a constant and precise manner. We have seen that, for instance, three seconds after the beginning of deglutition, the middle section of the esophagus begins to contract and remains contracted for about five seconds. But as we certainly sometimes do swallow again before the lower sections of the esophagus are relaxed, the question arose, How then could the morsels pass through the contracted sections? The experimental answer to this query brought to light highly interesting facts, which are briefly stated as follows: \* If a number of deglutition acts followed one another in rapid succession, then the peristalsis did not follow after each deglutition, but appeared after the last one, as if this had been the only one. If the deglutition acts followed one another in intervals of less than a second and a fifth, the entire œsophagus, including the first section, remained relaxed until a second and a fifth passed after the last swallow. If, further, the deglutition acts followed one another at intervals of more than a second and a fifth but less than three seconds, the first section of the esophagus contracted, but the second and third sections remained relaxed. If, finally, the interval between the deglutition acts was larger than three seconds, but less than six, the first and second sections contracted, but not the third. If a deglutition act occurred while any of the sections commenced to contract, the contraction had then its normal course, and the second contraction followed as if the deglutition had occurred after the contraction had stopped. For instance, if the deglutition act took place right in the beginning of the contraction of the second section, the contraction of this section lasted as usual about five seconds, and then followed an intermission of three seconds, after which this section contracted again. These results have been ascertained by the curves obtained from my esophagus by the method described above. We can establish the main phenomenon of our statement also through the gastric press sounds. If we listen at the epigastrium while many deglutition acts follow one another with greater or less rapidity, we hear the press sound only six seconds after the last deglutition

As a minor fact only I shall mention here that the morsel indeed shoots down even through a contracted section of the esophagus, as we have observed in our experiments, and as it can be well established by listening to the sound alongside the spinal column.

What does our main phenomenon signify? While the sequence of the peristaltic movements of the œsophagus, after a single deglutition act, can neither be destroyed nor even interrupted or delayed, we see that the entire peristalsis, or a part of it, is inhibited at the moment another deglutition act appears; in other words, the peristaltic movements pertaining to one deglutition act are inhibited by the appearance of another one. The disappearance of the peristalsis is, then, an inhibitory phenomenon, and each

<sup>\*</sup> Meltzer. Schluckgeräusche im Scrobiculus cordis. Ctribl. für die medicinische Wissenschaft, 1883, No. 1. Zu den Schluckgeräuschen. Berliner klinische Wochenschrift, 1884, No. 30.

<sup>\*</sup> H. Kronecker und S. Meltzer. Ueber den Schluckmechanismus und dessen nervöse Hemmung, Bericht der königl. Academie der Wissenschaft zu Berlin, January 24, 1881.

deglutition act exercises an inhibitory influence upon the parts belonging to the mechanism of deglutition. The inhibitory wave apparently sets in just at the beginning of the deglutition, as the appearance of the deglutition in a small fraction of a second before the beginning of the contraction is sufficient to inhibit just this contraction. But as the inhibition belonging to each deglutition act does not suppress the contractions pertaining to the same act, we have then to presume that the wave of inhibition is of very short duration.

The existence of the phenomenon in question we have also observed in animals, in dogs as well as in rabbits. In the latter animal the cardia again is the proper part for observation.\* As the entire duration of the peristaltic wave in a rabbit is not more than two seconds, the deglutition acts have to follow one another in less than this time. But as it is hard to induce a rabbit to swallow in a natural way with the desired rapidity, we have produced the rapid deglutitions by electrical stimulations of the central end of the superior laryngeal nerve. We were then able to establish the fact unmistakably that in rapid deglutitions the contraction of the cardia takes place only after the last deglutition act. Here, however, we observed another important fact. The cardia, which is usually in a state of tonic contraction, gets somewhat relaxed at the very beginning of each deglutition, and these relaxations increase with the greater number of rapid deglutitions. The relaxations are usually small and can be overlooked, but they can be brought out more clearly by the following arrangement: When a rabbit is made to swallow by stimulations of the superior laryngeal nerve, each swallow carries only air into the stomach; after a while there is in the stomach a considerable amount of air which stands under high pressure; its escape is prevented by the firm contraction of the cardia. If, now, the cardia relaxes, the air shoots into it and tends to dilate it. By this means we are well able to recognize the relaxation which takes place in the cardia with each deglutition act, and also the increase of these relaxations with the rapid succession of the deglutitions.

These relaxations of the cardia at the beginning of each deglutition demonstrate clearly the presence of an inhibitory function in the mechanism of the deglutition

What is the mechanism of the deglutition, what causes in the first place the precise sequence of the contractions of the several sections? Marshall Hall † thought that the bolus, while passing down the œsophagus, irritates the mucous membrane and thus causes the contractions of each place. But we have seen that the morsel passes down long before the contractions set in. We know further that the section of the vagi wipes out the peristalsis, while the stimulation of their peripheral ends produces a simultaneous contraction of the entire œsophagus, but not a peristaltie wave. The movements therefore can not be caused by the passing food, nor is their cause located within the gullet

Another theory was advanced by Wild \* and Ludwig. The contraction of an upper part, they say, gives rise by the way of reflex to the contraction of the adjoining lower part. The basis for their theory they found in the experiments they report-namely, that ligation or severance of the gullet excluded the peristaltic movements from the gastric end of the œsophagus. But experiments made later by A. Mosso t have shown a reverse result. We t have often repeated Mosso's experiments, and constantly obtained results similar to Mosso's. Even after removing the greater part of the esophagus in a rabbit, we observed the cardia contract in due time after each deglutition. This shows unmistakably that the cause of the sequence of the contractions is located entirely in the center of deglutition. When at the beginning of the deglutition an afferent impulse was once conveyed to the center of deglutition, it ran then the predestined course, sending out efferent impulses to each section of the gullet in due time, independent of the responses of the corresponding sections. Deglutition is then a single reflex act, with only one afferent impulse and many efferent nervous paths.

The next question is, In which part does the afferent impulse originate, and by which nerve is this impulse transmitted to the center? Concerning the latter point, I have already mentioned above that by the stimulation of the superior laryngeal nerve the deglutition can be promptly effected. The discovery of this fact has some interesting history. When Rosenthal # discovered the inhibitory effect of stimulation of the laryngeal nerve upon respiration, he noticed that during the stimulation there were some .peculiar motions of the larvnx, but he thought them to be of a respiratory character. It was not till some years later that Bidder | and Blumberg recognized the true nature of these motions. They established the fact that stimulation of the larvngeal nerve produces deglutitions. But they again report that, after deglutitions brought on by stimulation of the laryngeal nerve, no peristaltic motions were seen to be following in the esophagus, which statement is, of course, not true so far as it concerns a single deglutition act. The true meaning of their observation, however, is apparently this: any stronger stimulation of this nerve brings on quite a series of rapid deglutitions, and, as we have seen, under such circumstances the peristalsis does not follow any of the deglutitions except the last. Thus far they were correct in stating that, in the great majority of deglutition acts, no peristalsis followed. The last peristaltic movement, however, they have either entirely overlooked or considered it as an exception which does not break the rule. They have then probably seen the phenomenon of inhibition long before us, but did not understand the true meaning of it. In this connection I shall mention that Arloing A

also observed this fact before us, but did not enter into further explanations of it; and it is just its interpretation which gives prominence to our phenomenon.

Now, the superior laryngeal nerve, though very effective in artificial stimulations, is certainly not the carrier of the natural impulse. Wassilieff \*\* has cut the nerves on both sides without affecting in the slightest the natural deglutition. It should be mentioned that stimulation of the mucous membrane of the larynx is very rarely responded to by a deglutition act.

The other nerves which could come into consideration are the glosso-pharyngeal and the trigeminal nerves. Of the first nerve it has long ago been known that its section does not interfere with, and stimulation does not produce, deglutition. But also of the trigeminal nerve it has lately been shown by Wassilieff † and confirmed by Marckwald † that the successful intracranial section of both trigeminal nerves does not wipe out natural deglutition. We must then state that the question as to which of the nerves is the carrier of the afferent impulses producing natural deglutitions is not yet satisfactorily settled.

In a somewhat better position we seem to be respecting the carrier of the inhibitory impulse. By a series of experiments on dogs and rabbits, we—Professor Kronecker and myself \*—came to the conclusion that the glosso-pharyngeal nerve was probably the afferent nerve for the inhibitory impulse. If the glosso-pharyngeal nerve is stimulated simultaneously with the superior laryngeal nerve, the success of the latter stimulation is visibly impaired. A stronger stimulation of the glosso-pharyngeal nerve seems even to annihilate the effect of the superior laryngeal nerve for some time. These experiments have been repeated and confirmed by Wassilieff.

Concerning the parts where the natural impulses originate, Wassilieff a reports that in rabbits deglutition can invariably be induced by tactile stimulation of a circumscribed place in the oral surface of the soft palate. Wild \( \rangle \) and Ludwig, on the other hand, report that they could best produce deglutitions by touching the rhinal surface of the soft palate. In human beings, according to Wassilieff, no place could be found from where deglutitions could be produced promptly by tactile stimulations.

Apparently the experiments on the origination and transmission of the afferent impulses of the deglutition act leave yet ample room for further study.

A more satisfactory progress I am able to report concerning the localization of the center of deglutition. It was always placed in the medulla oblongata, but merely on anatomical grounds. In order to establish this view on an

\* Wassilieff. Wo wird der Schluck ausgelöst? Zeitschrift für Biologie, 1887, Bd. vi, p. 29.

experimental basis, we severed the medulla from its upper and lower connections. The deglutition remained intact so long as the artificial respiration was continued. On the other hand, the destruction of the medulla also destroyed the deglutition. For the special localization of the center within the medulla an experiment of A. W. Volkmann\* seemed to me to be very instructive. In an experiment Volkmann has seen the deglutition disappear after removing the brain, and he came to the conclusion that deglutition was mainly a voluntary act. Volkmann offers the fact that the respiration was not disturbed as a proof that he did not destroy the medulla. As we now positively know that the removal of the cerebrum does not affect the deglutition, I have come to the conclusion that Volkmann had indeed taken away a part of the medulla which contained the center of deglutition, and that this center has its place above the center of respiration. In my experiments on respiration I once, indeed, succeeded in dividing the medulla between both centers; stimulation of the superior laryngeal nerve in this case produced only inhibition of respiration and no deglutition. † The exact location of the center has been recently established by M. Marckwald.† In a series of sections through the medulla, Marckwald found that the location of the center of deglutition is just above the alæ cinereæ. A section through this place destroyed the reflex of deglutition without affecting the respiration. On the other hand, circumscribed destruction of the center of respiration did not affect deglutition,

After we established the fact that with each deglutition a wave of inhibition rapidly spread through the entire center, the question arose before me whether this inhibition did not irradiate into the neighboring spheres-i. e., whether the other centers of the medulla were not affected by this inhibition wave. # My attention was first turned toward the cardio-inhibitory center within the medulla oblongata. The function of this center is to keep up the inhibitory influence of the vagus upon the heart. The effect of inhibition upon this center would then be to lessen the tone of this center, and that means to increase the number of the heart beats. This, indeed, I found to be the case. A single act of deglutition already perceptibly increases the pulse rate. The increase is constantly followed by a less pronounced decrease. Both effects are more pronounced when a series of deglutitions follow one another in very short intervals. A pulse rate of seventy-two can be increased to a hundred and then decreased to fifty-six. This influence of the deglutition upon the heart-beat is dependent neither upon the amount nor upon the character or temperature of the swallowed mass. It is influenced only by the reflex act and the summation of these acts; the larger their number and the smaller the intervals between the

acts, the greater their influence upon the cardio-inhibitory center.

We have further observed an inhibitory influence of the deglutition upon the respiration. If we hold our breath until we experience a degree of dyspnæa, the uneasiness is then relieved for a certain time by rapid drinking. We can see the suspension of the respiration during rapid drinking even in a tracheotomized animal. The deglutition exerts an inhibitory influence also upon the tone of the vasomotor center; the pulse gets markedly softer during drinking. The fact has also been established by a more precise method. The inhibitory wave of the deglutition affects even functions the centers of which are located in the lumbar region of the spinal cord, like the contractions of the uterus or the erectio penis. In the latter case the deglutitory inhibition is efficient even when the cause is of peripheral origin, as in gonorrhæa, and is of practical value.

The depressing and soothing effect of a rapid succession of deglutition acts can also be observed in many pathological states-for instance, in certain forms of headaches, in asthma nervosum, in spasmus glottidis, etc. The relief in such cases is, of course, only temporary. In other conditions again, the inhibitory effect of the reflex of deglutition is indeed helpful, like in singultus or in syncope with slow heart-beat. A drink of water or some stimulating fluid is a popular remedy; but it is not the swallowed mass, it is the reflex of the act of swallowing which is the more effective factor. A tablespoonful of water drank in twenty swallows is more beneficial than a glass of wine poured down in large but few swallows. The stimulating effect of the alcohol can take place only through the medium of circulation, and after a lapse of time, while the increase of the pulse rate or the depression of a convulsive contraction occurs with the very act of swallowing,

I wish to mention that Wertheimer and Meyer\* have recently confirmed my statements of the influences of the deglutitions on the cardio-inhibitory and respiratory centers, so far as the human being is concerned; in dogs, however, they state that the conditions are different; here the deglutitions retard the heart-beat. I have not yet found the opportunity to verify this statement.

In conclusion, I have to mention briefly another influence of the deglutition upon the respiration. If the movements of the diaphragm are recorded by a pneumograph, we observe that with each deglutition a short, sharp descent of the diaphragm, an abortive inspiration occurs. This has been observed by Waller and Prevost, myself, Steiner, Knoll, and M. Marckwald. All now agree as to the active nature of this contraction, but I shall not discuss the explanations given by the different writers as to

\* E. Wertheimer et E. Meyer. Influence de la déglutition sur le rhythme du cœur. Travail du laboratoire de physiologie de la Faculté de médecine de Lille, 1er avril 1890. the origin of this phenomenon. I believe that none of the explanations given, including my own, covers the ground.

## INTRODUCTION TO THE DEBATE ON MENSTRUATION

BEFORE THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

AT ALBANY, February 6, 1894,

WITH REMARKS CONCERNING NORMAL MENSTRUATION.

BY ANDREW F. CURRIER, M. D.

In introducing this familiar subject in the form of a debate before this learned society my only apology, if apology were essential, is its everyday importance. Whether we are general practitioners or so-called specialists, there are few morbid conditions which we are called upon to investigate in women between the periods of puberty and the menopause in which the influence of menstruation may not enter as an important factor. Particularly in recent years, which have seen the wonderful development of the art of abdominal surgery, have the bearings of this function upon the general economy of the individual been the subject of much reflection and discussion, and not a little light has been contributed by the workers in this field.

I deem myself fortunate in being honored as usher or herald to the eminent gentlemen who will take part in this discussion. My work is mainly introductory, but I shall also beg to be allowed to make a few elementary remarks concerning the genesis of the menstrual function, and the normal performance of the same.

As animal life evolves from the lower to the higher we observe increased complexity of structure and function. The simple structure of an amæba, or of any of the forms of primitive life, is all that is necessary for its life work. As we reach relatively higher forms, like the polyp or the oyster, we find greater differentiation of structure for the relatively greater field of work. The same law continues as we advance to the stage of the higher vertebrates, and finally reach in man the ultimate which has been foreshadowed in the types and forms which have led up to him. The differentiation of the genital organs in individuals of separate sex begins very early in the scale of animal life, and the functions connected with those organs become more marked as we ascend the scale. Thus we pass from the ovipara, with their different gradations and varieties, to the vivipara, finally ending again in man. The phenomena connected with the impulse to reproduction in animal life are as clearly defined as any in the whole range of animal activity, and demonstrate the important relation which that impulse bears to physical existence.

The period or season of its occurrence is definitely fixed, due allowance for variations being understood; the vascular and nervous systems participate in a condition of irritation and excitement—in fact, the entire appearance and behavior of the individual undergoes a change. Some of the insects change their color when the reproductive impulse influences them; reptiles and fishes show unusual excitement, increase of glandular secretions, and hypersemia of

A Marckwald, Loc. cit.

the genital organs; birds have brighter plumage. In the higher mammalia there is present at such a time not only a change in their appearance and behavior, but a discharge of mucus, or mucus and blood, from the genital passage. It has been observed in mares, sows, ewes, asses, bitches, and cats, though it is less profuse in those animals which have hollow uteri than in those with thick and solid uteri resembling those of the human female. In the apes and monkeys—the animals nearest man—hæmorrhage from the vagina has been frequently observed, and in some instances it occurred with the same periodicity as in women. These statements have all been fully substantiated by the most accurate and intelligent observers of animal life (Buffon, Cuvier, Saint-Hilaire, Errenberg, Raciborski).

It appears, therefore, that the reproductive impulse is not only associated with decided congestion of the generative organs, but with a more or less abundant discharge of blood, particularly in the higher animals. The culmination of the animal series is man, and in woman we have not only the reproductive impulse accompanied with the bloody discharge, but we have it at fixed and relatively frequent intervals; we may even have the reproductive impulse and impregnation without the bloody discharge,\* and almost immediately after the conclusion of a previous pregnancy;† finally, as the evidence of the highest development in this direction, we may have the continually recurring bloody discharge without the reproductive impulse.‡

The terms menstrual and menstruation indicate that the function referred to recurs with monthly intervals intervening. There has been much ingenious speculation as to the reason for this particular interval—the menstrual wave, the menstrual cycle, etc., being carefully elaborated—but the ultimate facts are elusive. Some hints, wanting in definiteness, however, may be gathered from comparative zoology. Until we reach the primates the pelvic organs in most of the mammalia lie in the horizontal plane of the body. Sexual intercourse occurs only, as a rule, when the female is not pregnant, and its sole object is apparently the induction of pregnancy. With the primates, the erect posture being customary, the position of the pelvic organs is changed, and also the conditions of the pelvic circulation. Sexual intercourse, at least so far as man is concerned, is practiced without reference to the presence or absence of pregnancy. The repeated congestions accompanying the frequent performance of the sexual act may, at some time in the remote past, have tended to produce periodical increase in the tension of the pelvic circulation, and the discharge, which previously occurred only with or before sexual

intercourse, may then have transferred its appearance to the occasion of increased vascular tension.

Or we may adopt the theory of Pouchet, that the period of a lunar month is essential for the formation of a decidua, and that if in this decidua an inseminated ovum is not implanted, the object of the decidua would be at an end and degeneration and hæmorrhage would result.

The theory of Pflüger, that the periodical rupture of a Graafian follicle, with the attendant discharge of an ovum, hæmorrhage from the ovary, and pelvic congestion, are the essential elements in menstruation, is a very reasonable one, for in countless cases conception is referred with great probability or even certainty to the period immediately subsequent to menstruation; but the argument is not conclusive, for the discharge of ova is now believed to occur quite independently of menstruation, possibly from a very early period of life, and it is known that it continues in some cases long after menstruation has ceased.\*

The satisfactory explanation of the recurrence of menstruction at definite monthly intervals, therefore, remains to be presented.

The appearance of menstruation in a girl is usually accepted as evidence of maturity or womanhood. It is only one of the evidences, however, for associated with it are the development of the external genitals and the rounding of outline of the entire figure. It may be absent, maturity of the reproductive power being present notwithstanding. In civilized society it is usually regarded as a safe rule that one who has never menstruated, having reached the proper age to do so, is physically defective in some way, either on account of disease in early life or on account of some fault of structure. It does not follow that such a condition is irremediable—in fact, we know that in many cases it is not. Women who are thus affected ought not to marry until the actual condition of their generative organs has been ascertained and the cause of their defect removed if possible.

As menstruation is one of the evidences of maturity, it will make its first appearance at different ages in different parts of the world, for all women do not mature equally early. Those who lead a natural life will usually mature earlier than those who live artificially, though this rule is sometimes reversed; savages earlier than highly civilized women, inhabitants of warm climates earlier than those in cold, the analogy from vegetable life holding good; those living at high altitudes earlier than those at the seacoast-There are also peculiarities as to races, nations, and families which exert a modifying influence the same as in trees and plants. In this latitude the first menstruation seldom appears earlier than the thirteenth or later than the fifteenth year.

An analysis of two hundred cases from my private

<sup>\*</sup> This is seen in the frequent examples of those who become pregnant before they have ever menstruated. Among the Eskimos this is a very common fact, according to Dr. F. C. Cook, recently physician to the Pearv expedition.

<sup>†</sup> In the New York Journal of Gymecology and Obstetries for January, 1894, p. 125, is the account of a woman who bore a child July 4, 1892, had connection with her husband July 8th, and two hundred and forty-three days later was again delivered of a healthy child.

<sup>†</sup> This is seen in the case of women who do not marry, who devote themselves entirely to intellectual pursuits and continue to menstruate without the presence or the annoyance of the reproductive impulse.

<sup>\*</sup> Evidences of ovulation have been found in the ovaries of very young children. It has already been stated that there are many instances in which conception and delivery at term have occurred in those who have never menstruated. Cases are also reported in which conception and delivery at term have taken place years after the occurrence of the menopause. The writer is personally cognizant of three cases of this character, in one of which conception took place fourteen years after the menopause.

records, in which the nationality and age of first menstruation had been recorded, gives the following data:

Nationality	Number of cases.	Average age of first menstruation.
As a fine	110	141
America		4 - 4
Ireland	43	148
Italy	11	15,7
Germany	11	15,7
France	5	123
England	4	14
Sweden	4	, 167
Austria	3	15%

Scotland	1	16
Nova Scotia	1	18
Denmark	1	17
Russia	1	19
Switzerland	1	19
Poland	1	16
Greece	1	13

Of the two largest series of cases, one American menstruated first at ten, five at eleven, nine at twelve, twentyeight at thirteen, twenty-six at fourteen, eighteen at fifteen, thirteen at sixteen, five at seventeen, and five at eighteen; total, one hundred and ten.

Four Irish menstruated first at twelve, five at thirteen, fifteen at fourteen, six at fifteen, six at sixteen, four at seventeen, one at eighteen, one at nineteen, and one at twenty.

Nationality.	Date of earliest first menstruation.	Date of latest first menstruation.
Americans	10	18
Irish	12	20
Italians	13	18
Germans	13	18
French	11	15
Swedish	15	20
English		16

Average age of first menstruation for the entire two hundred cases, 14.5+ years.\*

No function of the body presents a wider range and variety of phenomena than menstruation; no function is more frequently disturbed. The complex conditions of civilized life are probably responsible for this, since the variations are few among those who are free from such conditions. Faults of structure, errors of diet and hygiene, disease in early life, exposure, fatigue, excesses of all kinds, act and react in producing a complex out of a simple function. The tension of the vessels in the pelvic circulation being increased as the period of menstruation approaches and the capillaries of the endometrium furnishing the area of least resistance, a discharge of blood within that area is the result. The quantity of blood lost will vary with the extent and continuance of the tensionthe vis a tergo-with the area and resistance of the endometrial vessels, and with the pressure exercised by the uterus to restrain and check the flow. A firmly contracting uterus may check the flow both suddenly and effectually, as is sometimes seen after the administration of a dose of

ergot or the influence of low temperature. An extensive new growth, such as myoma or cancer, may cause profuse flowing when added to the increased vascular tension of the menstrual period. With the blood is mingled the débris of broken vessels and the surface epithelium of the uterus and vagina over which the blood flows. The increased congestion of the uterus and vagina signifies increased activity in their glandular structure, and therefore increased discharge of their secretions. In this way the products of menstruation are accounted for.

The duration of menstruation is subject to many fluctuations, and is influenced and modified by many factors. It has almost as many types as there are variations in the number of days which it consumes. Reference has already been made to the "menstrual wave." This term implies an onward movement, a gradual increase of flow until the maximum is reached, and then a gradual decline or recession until the ordinary conditions of the pelvic circulation recur. But there are very many cases in which a discharge of blood is not the only phenomenon of menstruation. These accessory phenomena constitute the so-called moltimina of menstruation, and may precede the appearance of the flow for many hours. A complete menstrual period or experience consists, therefore, in moltimina plus flow, and may continue from a day to a week, or even slightly longer.

In the one day type the flow is scanty and the blood deficient in coloring matter—in fact, it is principally serum—and there may be scarcely enough of it to soil a single napkin. The other phenomena in this type of menstruation are usually very pronounced, especially cramps in the uterus, pain in the loins, and headache. It occurs in women with imperfectly developed uteri; in the anæmic, especially in the young; and in those who suffer with chronic diseases, such as pulmonary phthisis and nephritis.

In the two days' type the flow of blood may be free and of natural appearance the first day; the second it is scanty and watery. It is usually preceded by pain, as in the one-day type, and has anatomical conditions similar to that. In the three days' type the conditions may be quite normal as to the quantity of blood lost and the general condition of the patient from beginning to end, the flow reaching its maximum on the second day, then gradually ebbing and disappearing. Or there may be pain during the first day or two, varying in severity with the general and local physical conditions of the individual. Profuse hæmorrhage is seldom a marked feature of this type.

In the four-days' type the conditions may also be quite normal as to flow, pain, and general or local disturbance. This and the three days' type include the great majority of cases in which the function is performed naturally. But it also includes many cases in which hæmorrhage is abundant, cases in which the uterus is the seat of endometritis, malignant disease, or some other morbid condition. Pain is a much less prominent feature than weakness and exhaustion with such cases. The type lasting five to seven days is not usually so distinct as those of shorter duration. It may not be accompanied by any particular disturbance, nor leave the patient particularly weak or exhausted at its close. Should it continue a week, there is often little more than a

<sup>\*</sup> With the exception of the American series of cases, the numbers are, of course, too small in these tables to warrant any deductions as to national peculiarities.

mere stain the last day or two, without other manifestations. In some cases the flow and other symptoms cease entirely on the third or fourth day, recurring after an interval of a few hours, and continuing from one to three days longer.

Those who flow profusely five to seven days or longer are almost invariably sufferers with uterine disease of a more or less serious character. They can not properly be said to illustrate a type of menstruation, since menstruation is only an incident which for the time serves only to intensify their morbid condition.

A discharge of blood may be the only evidence to a menstruating woman that she is experiencing anything out of the usual course. Women who lead an out-of door life, who are robust and well developed, women who are without high nervous organization and are not very sensitive to pain, and women who are so intensely occupied that they seldom think of their own physical condition, may be ignorant, so far as their own experience is concerned, of the socalled menstrual molimina. Unfortunately, this can not be said of a great multitude of women, some of whom are well formed, more of whom are defectively formed or diseased. To them menstruation means not only a discharge of blood, in greater or less abundance, but a multiplicity of attendant discomforts and annoyances, which may amount even to the most intense physical or mental suffering. The term molimina is often applied to these bad sensations collectively. They are due mainly to the combined action and reaction of the vascular and nervous systems, especially to increased vascular tension and congestion, which may be regarded as the chief distinguishing feature of the function of menstruation. If this tension is not relieved through the natural channel, the pressure gives rise to pain. As the vas cular tension radiates away from the pelvis, the organs and tissues which are brought within the area of its influence respond to its stimulus, and pain or other sensations of discomfort are the result. Thus we obtain the well known variety of sensations in the pelvic organs, the liver, the kidneys, the stomach, the intestines, the brain, the skin-in fact, there is scarcely an inch of the body which may not react to the unpleasant impulses of the disordered function. The mental function, digestion, secretion, assimilation, may also be sharers in the disturbance, and the statement of its far-reaching possibilities for annoyance is sustained.

Thus we see that any existing morbid condition may be intensified as often as menstruation recurs. This fact is of great importance, for it should teach us to be on our guard to anticipate the evil consequences which may arise. It should teach us to guard against hæmorrhage in the presence of existing uterine disease, to insure rest, and other suitable precautions, if there is a tendency to mental disease or disease of the viscera or the skin, and, in general, to keep the patient under the most favorable conditions possible before and during the entire performance of the menstrual function.

From this review of the situation it may not be out of place to urge that it is the duty of the family physician to pay more attention than has heretofore been given to the instruction of the women, and particularly the young, who are under his care, concerning the precautions which they ought to exercise both before and after menstruation has been established. We can not be too particular and precise in this matter when we reflect that so large a portion of the disease which is peculiar to women arises from errors in connection with this function. Is there not a responsibility resting upon us which should induce us to insist that such errors and imprudence may no longer be practiced without our vigorous and persistent protest?

159 East Thirty-Seventh Street.

#### SENSORY AND PSYCHICAL EPILEPSY.\*

BY THEODORE DILLER, M. D.,

PHYSICIAN TO THE INSANE DEPARTMENT OF ST. FRANCIS'S HOSPITAL.

Most modern writers upon epilepsy (Gowers, Gray, Hirt, Dana) speak of certain mental disturbances which may precede, merge into, follow, or at times take the place of an epileptic convulsion. For instance, certain dream states may precede the typical attack, or automatic actions may constitute the attack itself; "epileptic mania" or automatism may succeed the attack, procursive epilepsy (running movements) may precede or take the place of typical attacks, etc. Nearly all who consider this subject seem to regard the motor convulsion as the most characteristic symptom (for it is always a symptom) of an epileptic attack. Only rarely is this symptom absent. Yet it is well known that an epileptic fit may occur characterized by no motor explosion whatever. Such attacks are regarded as rare, as bizarre, and are spoken of as epileptic equivalents (psychical epileptic equivalent, sensory epileptic equivalent, etc.), thus bearing witness to the idea that the motor explosion is generally regarded as the most characteristic phenomenon of epilepsy, if indeed not carrying with it the idea that the motor convulsion is the disease itself. It seems to me that our progress in the study of epilepsy is much retarded by the almost universal prevalence of this view.

The various symptoms of epilepsy, whether motor, sensory, or psychical, are due, it is now generally conceded, to sudden discharges of nerve force. This discharge may be due to disease of the nerve cells which discharge or to the inhibitory cells which normally control the discharging cells, or to a combination of both causes. This theory is borne out by the important investigations of Bevan Lewis, who finds very constantly in the brains of epileptics fatty degeneration, or, in advanced cases, vacuolation of the angular or inhibitory cells occupying the second layer in the motor cortex. It is doubtless true, as Gowers remarks, \$\frac{1}{2}\$ that "the wide variety of auræ seem to show that the primary discharge may occur in various parts of the cortex." The almost constant presence of unconsciousness as a

<sup>\*</sup> Paper read for the writer by Dr. M. L. Herr (Lancaster, Pa.) at the eleventh International Medical Congress, held at Rome, March 29to April 5, 1894.

<sup>+</sup> Text-book of Mental Diseases, p. 522 et seq.

<sup>†</sup> Diseases of the Nervous System, vol. ii, p. 754.

symptom in all varieties of epilepsy bears witness to the suddenness of the discharges; for, to again quote Gowers, "sudden—i.e., instantaneous—derangement of the function of any part appears incompatible with the integrity of consciousness."

Now the study of Jacksonian epilepsy shows that the initial movement in a motor convulsion (known as the signal symptom) points with great constancy to the cortical motor area for that movement as the seat of the greatest irritation. It further shows that the discharge originating in this center very frequently spreads to adjacent centers, and may in this way ultimately involve the entire one side of the patient, or, indeed, terminate in a general convulsion. It seems to me that these facts, taken in connection with our knowledge of the nature of epilepsy, point strongly to the probability that the initial symptom or aura, when there is one, points to the cortical representation of the disturbed part as the seat of the greatest irritation, just as the signal symptom does in Jacksonian epilepsy. But in essential epilepsy the discharge occurs more suddenly than in Jacksonian epilepsy, and consciousness is much more frequently lost. The discharge is communicated to adjacent areas with more rapidity and very generally involves the motor cortex if it does not arise in it, and, it seems probable, generally involves the entire cortex, or at least the greater part of it, before it ceases. Now in fits which begin with a psychical or sensory aura, the rapid supervention of unconsciousness and motor manifestations commonly obscures all other phenomena, rendering an investigation of them impossible, and the fit is said to be of the ordinary

In the same way fits which begin with motor manifestations unpreceded by aura are probably due to discharges beginning in the motor cortex.

If essential epilepsy were divided, as it seems to me would be warrantable with our present lights, into motor, sensory, and psychical, we would be in better position to scientifically study this much-studied but always interesting affection. If such a classification were adopted most cases of petit mal would resolve themselves into sensory epilepsies, while psychical epileptic equivalents, masked epilepsies, etc., would become psychical epilepsies.

As has been remarked before, the rapid supervention of unconsciousness and motor convulsions makes the study of sensory and psychical epilepsies very difficult. In the study of psychical epilepsy the observation of those cases in which convulsive motor symptoms are absent must in the present state of our knowledge prove of great value, and all such should be carefully recorded.

Pure psychical epilepsy is probably rare. It has been called "running epilepsy," epilepsia procursiva, and has been described by Mairet, Bourneville, Ladame, and others.

The case which I am about to relate would probably be described by some who have studied psychical epilepsy as one belonging to that class. But as there is a constant gustatory aura, I must, logically adhering to the classification which I have just advocated, call the case one of sensory epilepsy. The interesting features about the case are that while there are no motor convulsions, there are very

apparent psychical convulsions preceded by a gustatory aura.

The case is as follows:

S. M. (referred to me by Dr. J. J. Buchanan, December 30, 1893), male, Hebrew, aged twenty-two years. He was employed as an iron-worker, and enjoyed excellent health up to the beginning of his present illness. He has never used alcohol or tobacco to excess; denies specific history.

Five months ago he was struck on the head, in the frontal region, by a pair of iron tongs in the hands of a fellow workman. The blow rendered him unconscious for a few minutes. He says no scar was left, but examination reveals the presence of one in the right frontal region near the median line. It begins just a little back of the line made by the junction of the hairy scalp with the forehead and extends vertically backward and outward for an inch and a half. After this blow he began to suffer from general headaches, which came on at first every two weeks. But since September 21, 1893 (the date of his marriage), these headaches have occurred almost daily. Sleeps poorly at night; dreams a great deal. For some weeks past has been worrying a great deal on account of being out of work.

Two months ago-i. e., three months after the receipt of the injury referred to-he began to have peculiar "spells." These at first occurred once or twice a week, but rapidly increased in frequency, so that at the time I first saw him he was having four or five seizures daily. A "spell" is preceded by an aura, which he describes as a bitter taste in the mouth, and begins by restless or fidgety movements, accompanied by unconsciousness. He then walks up and down the room rapidly two or three times, making at the same time explosive utterancese.g., "This is a bad house! Let us fly from it!" "Rachel! let us get up and run off!" "See! see! the cars moving!" etc. He never falls or bites his tongue or suffers from any inco-ordinate muscular movements. His face changes during a fit, appearing to his wife "strange and yellow." The fits never last longer than a minute, and often less time. The explosive utterances differ in each attack, but the idea of fear seems to be constantly present. He will sometimes, but not often, give relevant replies to questions while in a fit. The spells terminate, leaving him slightly confused, but with no memory whatever of what he has said or done during them.

There has been, during the time the man has been under my care, some slight but constant elevation of temperature (99° to 99°6° F.), leading me to fear there may be a subacute or chronic meningitis in the region of the scar on the head.

That the seizures from which this patient suffers are epileptic can, I think, scarcely be disputed. The injury he received seems to have caused all the trouble. The record of the case speaks for itself.

Treatment, consisting in the use of the galvanic current and the administration of belladonna, bromides, and acctanilide, has caused the spells to recur with less frequency.

During the past ten days (February 24, 1894) he has had no spells, but complains of a constant coppery taste in his mouth, exactly similar to that which he experiences when the galvanic current is being passed through his head.

#### HEMICRANIA

AND OTHER NEURALGIC AFFECTIONS OF THE HEAD RELIEVED BY INTRANASAL SURGERY.\*

BY SARGENT F. SNOW, M. D.,

SYRACUSE, N. Y.

AURIST AND LARYNGOLOGIST TO THE HOUSE OF THE GOOD SHEPHERD
AND THE SYRACUSE FIRE DISPENSARY;

MEMBER OF THE CENTRAL NEW YORK MEDICAL ASSOCIATION,
THE SYRACUSE ACADEMY OF MEDICING, ETC.

The object of this paper is not to set forth a dogmatic claim of priority in presenting the subject, or that all cases coming under the above title can be cured by intranasal surgery. I well remember patients that were under my care while in general practice where gynæcological treatment in some, and correction of digestive disorders in others, brought the desired result.

My proposition is this: that there are a certain number of cases that can be cured, or at least relieved, by the proper treatment of pressures and contacts within the nose. In support of this I will read you notes of a few of the cases that have come to my notice during the past three years:

Case I.—Mrs. K., aged thirty-two years, referred to me by Dr. M. on April 16, 1892. Good family history and in comfortable circumstances. General health rather poor, unable to do her own housework, but better than she was a year ago, the improvement being due, she thought, to treatment given her for uterine trouble.

She complained of severe paroxysms of sick headache two or three times a week, most of the pain being over the right eye and in the temple. During these attacks, pains streaked up from the bridge of the nose; the eye was swollen and the surrounding areas were tender. She also had rushes of blood to the head. The nostrils were not stuffed, but she had frequent droppings of mucus into her throat. This train of symptoms had continued, with varying degrees of severity, for four years. I examined her nose, and found that she had good breath space; sæptum straight, but both middle turbinates were enlarged, pressing against the sæptum and outer walls. The one on the right side had also become overgrown downward, and pressed into the inferior turbinated.

Treatment was at once begun and continued until September 1st, during which time I had operated upon each middle turbinated by the snare, removing the enlarged anterior portion and clipping off the lower border that was pressing into the inferior turbinated on the right side. At that date she had been free from the headache and neuralgia for three months and a half. She then went out of town for a short visit, and while there had one of her old-time attacks. Upon her return she came to me, and I found, by deep exploration with the probe, a large pyramidal-shaped osseous growth at the junction of the middle with the posterior third of the sæptum, high up, pressing against the inner surface of the right middle turbinated.

This growth had been entirely unsuspected, and even then was hidden from view by that portion of the turbinated body in front of it, though, as you will remember, I had already removed the enlarged anterior tip. I operated on this deepseated growth with the electro trephine, December 20, 1892, since which time she has had no return of the headache or neuralgia until April 15, 1893. A short time before this I dis-

covered that a small fibrous bridge was being formed between the inner surface of the middle turbinated and the area upon which the growth had been located; this I removed, and applied a dressing of borated gauze between the opposing surfaces.

I did this on Saturday, and upon her next visit, two days later, she informed me that she had been suffering with a terrific attack of her old trouble. The pain began soon after she left my office, but was fully relieved upon removal of the offending pressure. Since that time she has had no return of the symptom, has improved in general health, and is now able to do her own work. No other treatment having been taken, it is with confidence we attribute her improvement to the intranasal work. Allow me to add that the bony growth mentioned, springing from the sæptum and impinging against the inner surface of the middle turbinated high up, usually hidden from view by a hypertrophied anterior tip, is not so rare as I at first supposed.

Within the past five months I have removed no less than six besides the one described. In nearly every instance I have found them only by deep, careful probing, and that done a few weeks after I had removed an overgrown anterior portion of a middle turbinated.

Case II.—Mrs. C., aged thirty years, a lady of rather slender figure, but able to do a part of her housework; mother of two children, one living. General health fairly good. Complained of a severe, steady pressure on the top of the head, of the size of a half dollar, sore to touch, but no swelling. This was usually accompanied by pains streaking in an irregular course from the bridge of the nose and from the back of the head up to the vertex. The paroxysms came on from one to three times each week, many times making her unfit for work for several days. She thinks she was never entirely free from the pressure on the top of the head since it began.

Incidentally I would remark that I have always looked upon this particular symptom as indicating some trouble with the uterus or its appendages, consequently I gave it only a passing notice when taking her history. Whenever she took cold neuralgic attacks would set in, often prostrating her for a whole day. Besides the above-mentioned symptoms, there were frequent attacks of dyspnea, forcing her often to leave church, waking her from a sound sleep at night, and sometimes causing her to stop in the street and catch something for support until the seizure passed away.

She had some dropping into her throat, but did not soil many handkerchiefs. Occasionally she had tinnitus, walked with her mouth open, but could breathe through her nose when quiet. These symptoms continued for the past five years, during which time she had been operated upon by Dr. V. for laceration of the cervix. This was followed by an improvement in her general condition, but her neuralgic troubles were not materially relieved. When she came under my care, January 17, 1893, I found comparatively free breath passages and regular nostrils, but each middle turbinated body had undergone a cystic enlargement of the bone in its anterior portion, until they were about the size of a marrowfat bean, crowding the outer walls and sæptum so closely in some places that I could not pass a No. 5 piano-wire loop around the one on the right side.

I finally succeeded in snaring the one on the left side, February 2d, and removing the other, piece by piece, with forceps, three weeks later. The last operation was followed by a complete cessation of the pressure on the top of the head, tenderness over the bridge of the nose, streaking pains to vertex, and the dyspnea, though a deep-seated pain in the right eye would come on if she read or sewed even for a few minutes. A

<sup>\*</sup> Read before the Onondaga County Medical Society, at Syracuse, June 13, and before the Cayuga County Medical Society, at Auburn, N. Y., July 13, 1893.

short rest would bring relief. At my suggestion, she consulted Dr. Marlow, who fitted her with glasses, so that now she tells me, June 12, 1893, that even that trouble is removed. Her general health is first class; all catarrhal symptoms are better, and she is able to breathe through the nostrils while walking.

CASE III .- Mr. K., aged fifty-six years, timekeeper in one of the large industries of our town; referred to me by Dr. M. General health fairly good, though not robust. Had been bothered for several years with a stuffed-up nose; severe pain over right eye and temple, especially after a day of severe mental labor. Examining nose, I found nostrils pretty well filled with a yellowish boggy membrane, the upper third being one mass of thickened tissue; both middle turbinates enlarged in their bony and membranous structures. I began operations on him April 20, 1893, and finished October 1st, removing, during this period, the hypertrophied anterior tips of the middle turbinates, cauterizing the thickened tissues, where necessary, stimulating degenerated membranes, and in other ways restoring the nasal functions. The result is that he informed me by telephone this day, June 12th, that he had suffered no return of his hemicrania, though he is still engaged in the same kind of work, only more of it. He breathes freely through his nose, and the catarrhal manifestations are much improved.

Case IV differs from the preceding in that it was not referred to me especially for the cranial neuralgia, but came for ear treatment. Mrs. Y., aged forty-eight years, a lady from Johnstown, N. Y., who consulted me about a year ago for catarrh of the middle ear. Incidentally she remarked that there was a constant dull, heavy pain at the back of the head, just above her neck, which had bothered her for five years. Examination disclosed a long bony shelf extending across the left nostril. This I removed by the saw, as a necessary part of the treatment I was giving her for the ear affection, with the result that the peculiar pain was at once relieved, and she now writes me that it has never returned.

In looking over my records, I find notes of many other cases in which intranasal surgery has brought just such unexpected and satisfactory results, until now it has become my rule to advise all patients with cranial neuralgia, chronic ear, nose, or throat trouble, to have each contact and presure within the nose removed. It may not cure every one, but that it does materially relieve a large proportion of cases goes without saying.

Note.—Since writing this I have collected five additional cases in which pressure on top of the head accompanied hemicrania, or was coincident with the neuralgic affections. Three of them have been relieved by intranasal work; two of them are now under treatment. I have also collected four more cases of well-marked hemicrania in which the correction of nasal disorders has brought happy results.

117 East Jefferson Street.

The New York State Lunacy Commission.—At a meeting of the Medical Society of the County of New York held on February 19th, to consider the resolution offered by Dr. Dana at the January meeting and referred to the Comitia Minora, after a careful consideration and discussion of the matter of friction between the State Lunacy Commission and certain of the State hospital superintendents, the following resolution was unanimously adopted:

Resolved, that the Comitia Minora does not deem it advisable to recommend to the society the indorsement of the bill pending in the Legislature abolishing the Lunacy Commission.

This action of the Comitia Minora was unanimously indorsed by the society at the stated meeting of March 26th. THE

NEW YORK, SATURDAY, MARCH 31, 1894.

A BILL TO REDUCE THE ARMY MEDICAL DEPARTMENT.

Congress is once more engaged in reducing the army. This time the medical staff is to be the sufferer. The act of June 26, 1876, reduced the number of assistant surgeons from a hundred and fifty to a hundred and twenty-five. Now a further reduction to ninety is urged by the Military Committee of the House. This action is based upon the decrease in the number of stations which has occurred during the last decade. The committee say that if a staff of a hundred and ninety-two medical officers was sufficient to attend to the professional wants of two hundred and ten stations, then, certainly, a hundred and fifty-seven surgeons (the number proposed by the committee) should be quite ample for a hundred and twenty military garrisons. There is nothing like figures to prove a slight matter of this kind.

Just here the committee have fallen into a grave error. It should not be forgotten that when, in 1876, the number of medical officers was reduced to a hundred and ninety-two (the present number) there were, in addition, employed by the military establishment, a hundred contract surgeons. So late as 1886 there were still employed sixty-five contract surgeons, and the services of the last of these were not dispensed with until June, 1892. It would seem that, if the committee had given this subject thoughtful consideration, it would have appeared self-evident that a hundred and ninety-two surgeons could never, by any possible manner of means, supply the wants of two hundred and ten separate military posts. One might as well imagine that a hundred and ninety-two commanding officers could command two hundred and ten separate garrisons.

Granting that the stations have been reduced by gradual concentration of troops to a hundred and twenty, the committee have made no allowance whatever for the discharge of a hundred contract surgeons since 1876, who had been largely employed on detached service in the field, with scouting parties, and whose places must now be supplied by the regular members of the corps; and they have made no allowance for sick and disabled officers, for those entitled to leave after an extended Western tour, or for those who, under our military system, must be detailed for purely administrative duties. When these have been deducted, it will be seen that the number allowed by law is not in excess of the plain requirements of the service.

If this bill should pass, then two most important measures for the good of the medical corps and the army, both instituted by the new surgeon general, must promptly fall to the ground. We refer to the establishment of the new Army Medical School for the instruction of recently appointed assistant surgeons and to the privilege of a year's tour of duty in the larger medical

centers extended to a few of the senior assistant surgeons solely for the purpose of professional improvement. For these reasons, and because we believe that the bill is in the line of a false economy, we hope to learn of its prompt rejection by Congress.

#### TWO KINDS OF MEMORY.

From careful observation and deliberate reflection upon the facts observed, the writer is convinced that there are at least two radically different forms of memory, neither of which is convertible by effort or education into the other; and that these forms of memory are seldom present in like degree in the same individual, one form in fact being often very feebly marked where the other is unusually prominent. In the early vears of school life the child awakens to the fact that some members of his class have great facility for learning by rote; yet experience shows that these members are often distanced in the final examinations by competitors whose power of learning by rote is very slight; and still greater experience will often prove that these pupils of "rote" memory do not become the most useful or successful citizens. Every medical school, perhaps, boasts its professor whose "wonderful memory" enables him to roll out great strings of complicated therapeutical formulæ or to tell with a flourish on what side of a particular page and how far down its column a statement quoted is to be found. Yet this professor is very probably inferior in breadth of thought and in originality of practice to some colleague who occasionally in lecturing forgets even simple formulæ and confesses that names of authorities often slip his memory most unexpectedly.

It has been the fashion among educators, and with the public as well, to honor greatly the former sort of memory, giving prizes to the pupil who can learn by rote with the greatest facility. In fact, the histories and geographies of thirty years ago seemed to be specially constructed for showing off the merits of this form of memory. Even now the public feel a grudge toward the man who does not recognize the casual acquaintance of a week ago when he passes him on the street. As far as can be judged by one who possesses this former sort of memory in very feeble degree, it is dependent upon a process, somewhat akin to photography, by which the details of objects presented to either the physical or the mental eye are fixed in outline upon the sensorium. Recollection consists in turning the mental gaze upon the photograph thus recorded. It is said of a certain artist, famous as an illustrator of books, that after driving through a park he could at will picture to himself the grouping and individual outlines of the trees which he had passed. The writer knows a little boy who, when about five years of age, would draw from memory a picture of a railway locomotive with details of outline which would be doubted by his elders until investigation proved that they represented minor portions of the engine. Other instances of the development of this "photographic" memory pari passu with the earliest unfoldings of a child's perceptive powers will occur to the observant reader.

The second form of memory may be termed "logical." It appears less brilliant to the casual looker-on. It is apparently developed later; not because it is not, like the other, inborn in the structure of the mind, but because the reasoning faculty is developed more slowly than physical sight. Compared with "photographic" memory, it has color, which sometimes obscures detail of outline. The possessor of "logical" memory places little value upon naked facts or figures, but appropriates such as have important bearings, which can be perceived, upon other facts of known value. In moments of leisure his mind is engaged, not in roving at random over the impressions of the past, but rather in working out the relations between certain isolated things observed and deducing conclusions from these relations. These abstract processes of thought make him inattentive to many details in his present surroundings which would be impressed upon a "photographic" memory. As reflection is a higher faculty than observation, so the "logical" must be superior to the "photographic" memory. This becomes evident also if we compare the man of "logical" memory, who has well founded opinions of his own, with the man of "photographic" memory, who can give only the opinions of other persons, or the mature historian with the small-talk conversationist.

Both varieties of memory should be cultivated, for the best memory is that in which both are present in due proportion; but the average mind does not, in its original constitution, embrace both in equal degree. It is obviously unfair to punish the school-child who possesses a well-developed "logical" memory because he has not equal "photographic" perceptions; and it is unjust to brand the man of "logical" memory, who offers fine reasoning powers and stores of well-ordered facts of value, as one who has "a miserable memory," simply because he occasionally overlooks unimportant details.

## PRECAUTIONS TO BE TAKEN AFTER DEATH OR RECOVERY FROM THE ACUTE INFECTIOUS DISEASES.

The Union médicale for January 27th contains an article on this subject in which the writer says that, if death follows an infectious disease, the body should be prepared for burial as soon as possible. It should be bathed in a 1-to-2,000 solution of corrosive sublimate and put into a coffin and packed with sawdust which has been thoroughly wet with the same solution. The interment should follow with as little delay as possible.

If the patient recovers, isolation should still continue, and he should not come in contact with others until a sufficient length of time has elapsed, according to the nature of the disease. The Académie de médecine has decided that isolation should begin from the day when the eruption first appears, and continue for forty days in small-pox, scarlet fever, and diphtheria, and twenty-nine days in chicken-pox, measles, and numps, and should not end until after the patient has taken two or three baths, followed by thorough friction (including the head). These precautions may seem somewhat rigorous-

for ordinary practice, and they may be modified, at least in light cases, where, after convalescence, one bath lasting half an hour is sufficient. All clothing belonging to the patient should be thoroughly disinfected before being worn again.

Whether the patient dies or recovers, the same precautions are to be taken with regard to the clothing and the apartment. The linen, bedclothing, and towels should not be sent to the wash until after they have been passed through such a solution as was used during the course of the disease. All such articles as carpets, curtains, etc., should be sent to the steam disinfecting bath, and all other articles that can not bear the temperature of the steam bath must be disinfected with spraying or antiseptic lotions. In localities where there are no steam disinfecting baths, sulphurous acid must be used. As small a room as possible is to be employed in this method of disinfection, and six hours is a sufficient length of time for the process. All articles disinfected in this manner should be exposed to the air for several hours before being used again.

#### MINOR PARAGRAPHS.

#### PANCREATIC COLIC.

The Gazette hebdomadaire de médecine et de chirurgie for March 10th contains an abstract of an article by M. Mirmich published in the Berliner klinische Wochenschrift, in which the author relates the case of a man, sixty-eights year old, who was subject to attacks of hepatic colic, followed each time by the expulsion of typical calculi of cholesterin. After a time the character of the colic bad changed; the pain under the left ribs and in the epigastrium having spread to the shoulder blade, there was no icteric coloration, the stools remained colored, and the urine contained no biliary pigment. A daily examination of the stools, made during the last attack, revealed concretions and small calculi of a peculiar character. They were malleable and easily crushed between the fingers, and presented a smooth surface on being cut. They contained no crystals or morphological substances; they dissolved in chloroform, and, after combustion, left a residuum containing acid carbonate and acid phosphate of calcium. According to the author, these characteristics suffice to distinguish the calculi in question as the second variety of pancreatic concretions. They might be taken for intestinal calculi, but the concomitant existence of colic confirms the diagnosis of their pancreatic origin.

#### TYPHOID FEVER IN PARIS.

AT a recent meeting of the Paris Academy of Medicine, reported in the Mercredi médical for March 7th, the subject of the unusual prevalence of typhoid fever in the city was introduced by M. Bucquoy. Among the others who spoke on the question were M. Lancereaux, M. Lereboullet, M. Armand Gautier, and M. Vallin. It was agreed that the water supply had become dangerously contaminated, and a resolution was adopted unanimously advising the citizens to boil the water before using it for drinking or cooking purposes.

#### PARISIAN HONORS TO MEN OF SCIENCE.

According to the Progrès médical, certain streets in Paris newly opened or renamed, are to be known by these names:

des Fontis, rue du Docteur-Blanche, rue Orfila, rue Dupont-del'Eure, rue Guyton de Morveau, rue Vulpian, rue Paul-Gervais, and rue Wurtz.

#### " ALLIGATORIN."

This, according to the Apotheker-Zeitung, quoted in the Deutsche Medizinal-Zeitung, is a mixture of the purified fat of the alligator and cotton-seed oil, recommended by a Cincinnati gentleman as a basis for ointments.

#### ITEMS, ETC.

Infectious Diseases in New York .- We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 27, 1894:

DISEASES.	Week ending Mar. 20.		Week ending Mar. 27.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	0	0	0	0
Typhoid fever	11	3	12	2
Scarlet fever	178	12	156	13
Cerebro-spinal meningitis	0	0	0	0
Measles	331	23	350	30
Diphtheria	200	41	227	48
Small-pox	28	8	18	4

Fractures of the Lower End of the Radius with Forward Displacement of the Carpal Fragment.-Dr. John B. Roberts, of Philadelphia, asks us to inform our readers that he is particularly anxious to know of any cases of fracture of the lower end of the radius with forward displacement of the carpal fragment. Notes of cases, references to published reports, or information of specimens in museums will be of much interest to him. Dr. Roberts's address is No. 1627 Walnut Street.

The Cartwright Lectures of the Alumni Association of the College of Physicians and Surgeons.—The course for 1894 will be delivered at the New York Academy of Medicine, No. 17 West Forty-third Street, on Wednesday evenings, April 4th, 11th, and 18th, at eight o'clock, by Professor Russell H. Chittenden, Ph. D., of Yale University, on the subject of Digestive Proteolysis.

The New York Post-graduate Medical School and Hospital.—The directors have sent out invitations to an informal reception to be held in the new building on the northeast corner of Second Avenue and Twentieth Street, on Thursday afternoon, April 5th.

The Chattanooga Medical College held its annual commencement exercises on Tuesday, the 13th inst. The graduating class numbered forty-nine.

The Edinburgh Obstetrical Society.-We learn that Dr. David D. Jennings, of New York, has been elected a fellow.

The late Dr. John H. Sinnett .- On March 24th the following preamble and resolutions were adopted by the medical staff of the Demilt Dispensary:

Whereas, We have learned with the deepest regret of the untimely death of Dr. John H. Sinnett, incurred in the discharge

Resolved, That the medical staff of the Demilt Dispensary desire to put on record their appreciation of the high standing Rue Quatrefages, rue Claude-Vellefaux, rue Charles-Robin, rue of their late colleague, their feeling of loss sustained by the 404

profession in this early death, and their heartfelt sympathy with his bereaved wife and family.

Resolved, That a copy of this resolution be forwarded to the Medical Record, the New York Medical Journal, and his family.

[Signed.] HENRY D. CHAPIN, M. D.,
JOHN DORNING, M. D.,
JOSEPH E. WINTERS, M. D.,

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 18 to March 24, 1894:

- Hall, William R., Captain and Assistant Surgeon, is relieved from duty as attending surgeon and examiner of recruits at San Francisco, Cal., to take effect upon the completion of his examination for promotion, and will then report in person to the commanding officer, Whipple Barracks, Arizona Territory, for duty at that post.
- So much of Par. 8, S. O. No. 60, March 12, 1894, from A. G. O. as relates to McVay, Harlan E., First Lieutenant and Assistant Surgeon, is amended to direct him, on being relieved from duty at San Carlos, Arizona, by First Lieutenant Straub, Assistant Surgeon, to report in person to the commanding officer, Fort Huachuca, instead of Whipple Barracks, Arizona Territory.
- CEONKHITE, HENRY M., Major and Surgeon, is relieved from duty at Fort Clark, Texas, and ordered to report in person to the commanding officer, Fort Reno, Oklahoma Territory, for duty at that post, relieving Gorgas, William C., Captain and Assistant Surgeon. Captain Gorgas, on being thus relieved, will report to the commanding officer, Fort Barrancas, Florida, for duty at that post, relieving Woodson, Robert S., First Lieutenant and Assistant Surgeon.
- Woodson, Robert S., First Lieutenant and Assistant Surgeon, on being relieved by Captain Gorgas, will report in person to the commanding officer, Fort McIntosh, Texas, for duty at that post, and for field duty in the Department of Texas, relieving Ten Eyok, Benjamin L., First Lieutenant and Assistant Surgeon. Lieutenant Ten Eyok, on being thus relieved, will report to the commanding officer, Fort Clark, Texas, for temporary duty at that post.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending March 24, 1894:

Spratling, L. W., Surgeon. Ordered to the U. S. Steamer Alert.

Deer, E. J., Surgeon. Ordered to the U. S. Steamer Raleigh.

Shipp, E. M., Assistant Surgeon. Ordered to the U. S. Steamer Raleigh.

Braisted, W. C., Passed Assistant Surgeon. Ordered to hold himself in readiness for U. S. Steamer Columbia.

HARMON, G. E. H., Surgeon. Detached from the U. S. Steamer Yorktown and granted three months' leave.

LUMSDEN, G. P., Passed Assistant Surgeon. Ordered to the U. S. Steamer Yorktown.

MACKIE, B. S., Surgeon. Ordered to the U.S. Receiving-ship Franklin.

Braisted, W. C., Passed Assistant Surgeon. Detached from the Naval Hospital, New York, and ordered to the U. S. Steamer Columbia.

EVANS, S. G., Passed Assistant Surgeon. Detached from the Naval Hospital, Philadelphia, and ordered to the Naval Hospital, New York.

FARWELL, W. G., Surgeon. Ordered to the U. S. Steamer Columbia. Marine-Hospital Service,—Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the Four Weeks ending March 17, 1894.

- FESSENDEN, C. S. D., Surgeon. Detailed as chairman of the board for physical examination of Assistant Surgeon L. E. Cofer. March 6, 1894.
- PURVIANCE, GEORGE, Surgeon. Detailed as chairman of the board to inspect Reedy Island Quarantine. February 20, .1894. To report at bureau for temporary duty. March 2, 1895.
- HUTTON, W. H. H., Surgeon. Detailed as chairman of the board for physical examination of the Inspector of Hulls. March 9, 1894.
- GASSAWAY, J. M., Surgeon. Detailed as recorder of the board for physical examination of Assistant Surgeon L. E. Cofer. March 6, 1894.
- Godfrey, John, Surgeon. Detailed as chairman of the board for physical examination of candidate, Revenue-Marine Service. March 6, 1894.
- IRWIN, FAIRFAX, Surgeon. To proceed to Paris, France, for special duty. February 24, 1894.
- MEAD, F. W., Surgeon. Detailed as chairman of the board for physical examination of candidates, Revenue-Marine Service. March 10, 1894.
- CARTER, H. R., Surgeon. To report at bureau for special duty. March 14, 1894.
- BANKS, C. E., Passed Assistant Surgeon. To proceed to Portsmouth, N. H., as inspector. March 12, 1894.
- KALLOOH, P. C., Passed Assistant Surgeon. Granted leave of absence for thirty days. March 12, 1894.
- GLENNAN, A. H., Passed Assistant Surgeon. Detailed as member of a board to inspect Reedy Island Quarantine. February 20, 1894.
- WASDIN, EUGENE, Passed Assistant Surgeon. Granted leave of absence for sixteen days. March 3, 1894.
- KINYOUN, J. J., Passed Assistant Surgeon. To report to the chairman of the Committee on Ventilation and Acoustics, House of Representatives, for special duty. February 21, 1804
- WOODWARD, R. M., Passed Assistant Surgeon. To report at bureau for special duty. March 14, 1894.
- GUITÉRAS, G. M. Passed Assistant Surgeon. Granted leave of absence for twenty days. February 19, 1894.
- STIMPSON, W. G., Assistant Surgeon. Granted leave of absence for twenty-five days. March 5, 1894. Detailed as recorder of a board for the physical examination of inspector of hulls March 9, 1894.
- HOUGHTON, E. R., Assistant Surgeon. Ordered to examination for promotion. March 3, 1894.
- ROSENAU, M. J., Assistant Surgeon. Ordered to examination for promotion. March 6, 1894.
- COFER, L. E., Assistant Surgeon. To report to board for physical examination. March 6, 1894. Placed on "waiting orders." March 15, 1894.
- GARDNER, C. H., Assistant Surgeon. Detailed as recorder of a board for the physical examination of candidates for the Revenue-Marine Service. March 10, 1894.
- STEWART, W. J. S., Assistant Surgeon. Detailed as recorder of a board for the physical examination of candidates for the Revenue Marine Service. March 10, 1894.

#### Society Meetings for the Coming Week:

MONDAY, April 2d: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society (private), New

York; Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; St. Albans, Vt., Medical Association (annual); Boston Society for Medical Observation; Providence, R. I., Medical Association; Hartford, Conn., Medical Society; South Pittsburgh, Pa., Medical Society; Chicago Medical Society (annual).

Tussnax, April 3d: New York Neurological Society; New York Obstetrical Society (private); Buffalo, N. Y., Medical and Surgical Association (annual); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Broome (quarterly) and Niagara (quarterly—Lockport), N. Y.; Hudson, N. J., County Medical Society (Jersey City); Essex, N. J., County Medical Society (annual—Newark); Union, N. J., County Medical Society (annual—Elizabeth); Androscoggin, Me., County Medical Association (Lewiston); Chittenden, Vt., County Medical Society; Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, April 4th: Harlem Medical Association of the City of New York; Society of the Alumni of Bellevne Hospital, New York; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (Stapleton); Penobscot, Me., County Medical Society (Bangor); Bridge-

port, Conn., Medical Association.

THURSDAY, April 5th: New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Washington, Vt., County Medical Society; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington).

FRIDAY, April 6th: Practitioners' Society of New York (private); Baltimore Clinical Society.

SATURDAY, April 7th: Clinical Society of the New York Postgraduate Medical School and Hospital; Manhattan Medical and Surgical Society, New York (private); Miller's River, Mass., Medical Society.

## Retters to the Editor.

THE AMERICAN SANITARY ASSOCIATION.

Groveland, Mass., February 7, 1894.

To the Editor of the New York Medical Journal:

Sir: Will you kindly permit me to make a statement concerning the American Sanitary Association, which is being organized as a national medical society? As secretary, I have received several letters from members and friends of the American Public Health Association, who have in some manner received the impression that our association aims to rival the American Public Health Association. This idea is erroneous. I am sure we all appreciate the useful and honorable career of that association. Briefly stated, the objects of our association are to discourage the manufacture and sale of impure and injurious foods and medicines, and to encourage the introduction of wholesome and honestly manufactured articles of food, medicines, clothing, and sanitary appliances in general. I sincerely hope that our efforts will meet with the approval of the medical profession and those interested in sanitary reforms, whether members of the American Public Health Association or not. There is ample field for more than one sanitary association in this country, and there is no reason why we should consider the ground already occupied. I should be very glad to answer any inquiries or furnish any information in my power to those interested.

W. THORNTON PARKER, M. D.

## Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of February 28, 1894.

American Grippe, or Myxoid Œdema,—Dr. Carl Seiler read a paper in which he said:

In 1885 I observed the first case of this peculiar disease. I afterward (in 1887) discussed the subject with Dr. Glasgow, of St. Louis, who, strange to say, had made observations similar to my own; and as there was no disease which had been described which, to our knowledge, came anywhere near the one under discussion, he had called it "It," and so had I. The disease was first described by me in a paper published in April, 1889. Dr. Glasgow reported his observations to the American Laryngological Association in May, 1889, and in June of the same year I read my paper before the American Medical Association at its meeting at Newport. You may remember that at that time I referred to the fact that the disease was spreading all over the country, and that I had received letters from Montana, Washington, the Canadas, from the South, and, in short, from all directions, after having made inquiry about the new disease. Geographical situation, elevation, temperature, and atmospheric conditions apparently had nothing to do with its causation; in fact, the disease was everywhere the same in its specific characteristics.

In 1889, in the month of December, the disease broke out in New York city, where it assumed the proportions of a very alarming epidemic, and its existence was recognized as an epidemic general and fatal all over the United States within a very few weeks after its recognition in New York. Unfortunately it was called la grippe, or the Russian influenza, a diseasé differing entirely in its clinical character and prominent pathological lesions from the disease erroneously named by the public press. I then published a paper in March, 1890, in which I gave the diagnosis between the Russian influenza, or la grippe, as well as of other diseases mistaken for it, and the American disease. Last March (1893) I published the fourth edition of my book on Diseases of the Throat, in which I devoted an entire chapter to the consideration of this disease, under the name of "American grippe," or myxoid ædema, to distinguish it from the "Russian" or European influenza. The distinction is similar to that which we are accustomed to make between measles and German measles, or morbilli and rubella (Rötheln).

The peculiar symptoms of the American grippe are: The sudden onset; the rheumatic pains in all parts of the body accompanying the sudden onset; an abrupt rise in the temperature, with moist skin; a peculiar tension; no inflammation of mucous membranes. In some cases a deposit of pseudo-membrane occurs upon the tonsils and elsewhere, which, however, is of entirely different character from the pseudo-membrane of croup and of diphtheria. There is a peculiar puffiness of the mucous membranes, which shows itself wherever the deposit is most developed. It occurs in the throat, in the larynx and nose, in the bronchial tubes, and in the mucous membrane of the intestinal tract. In its prostration of the vital powers of the body the disease is something like typhoid fever; but with it there is no fever, no exacerbation of high temperature; there is no thirst, no dryness of the skin, and no brown coating of the

tongue. In one case the temperature was 105° F. at the beginning, but it went down to normal in twenty-four hours. The pulse was 76 right along, and had none of the characters of a fever pulse. In those cases in which death occurred the temperature was reduced to normal, or even subnormal, and the giving out of the heart was the original cause of death.

In some cases the submucous infiltration is most evident in the vocal bands, and here the consequent closing up of the larynx causes suffocation. The immediate cause of death is usually a small hemorrhage in the nucous membrane in such cases. Ecchymotic spots are often observed in the throat, bronchial tubes, and also in the stomach and intestines. Indeed, there may be black vomit, like the black vomit of yellow fever, and the stools may also show the presence of effused blood.

I am now speaking of the symptoms of American grippe. I need not refer to the symptoms of Russian grippe, since I could not add anything to the admirable review of them given by my friend Dr. J. C. Wilson in his article on Epidemic Influenza, in Pepper's System of Medicine, which you are already familiar with.

In the matter of treatment I have found the greatest benefit from a long-discarded drug-which, I must admit, is of no use in any other disease-the benzoate of sodium. In American grippe it acts as a specific, precisely as quinine acts in malarial fever. It relieves the pain at once, it brings down the temperature, it relieves the oppression of breathing, and removes the false membrane from the throat. This remedy, with alcohol and rest, constitutes the whole treatment of the disease. In my experience I have found that it is an absolute specific-of course, provided that the diagnosis had been correct. As to other drugs, I would say that all those patent coal-tar remedies are only a cause of death. They act as heart depressors, when the heart is already profoundly depressed by the disease. Antipyrine, antifebrine, and all the other antis are worse than useless. The heart needs to be supported, and they all cause further depression. Quinine is often a cause of insanity and suicide. During the last three years I have made a careful investigation of all published cases, whenever possible, where in-Sanity had been the cause of death in grippe, and I found that quinine in large doses had always been given to the patients. I have observed in my own cases that even very small doses of quinine will often cause mental disturbance.

Thus far I have considered only the acute condition. If benzoate of sodium is not given, and the patient does not remain in bed, a chronic condition of grippe will be produced. This is a very distressing condition, as I know from personal experience. The symptoms are so different that they can not be given in detail, and it is difficult to make a diagnosis. There is a flabby, pale, or coated tongue, want of appetite, impaired digestion, irregularity of bowels. With this there is a depression of spirits, want of ambition, and inability to perform any work requiring exertion of mind or body. A little overexertion will throw the patient back, and it will be days and days before he can regain his former position and begin to gain strength.

The pathology of the chronic cases has been shown to be a slow process of fatty degeneration of all the organs of the body except the kidueys. And, if there has not been pre-existing disease of the kidneys, there will be no albumin in the urine.

The chief symptoms of the chronic form are general neurasthenia, associated with chronic distention of the venules, and anomia of the arterioles throughout the body. This was seen by ophthalmoscopic examination in the eyes, where it produced impaired vision or blindness. Blueness of the skin is due to the same venous congestion, evidently of neurotic origin. Besides

the mental depression, there are hallucinations of peculiar character and irritability of temper. Light has a depressing effect, while darkness causes exaltation. Toward evening the patient usually feels much better than in the early part of the day. I have observed that a patient may go to sleep at ten o'clock and wake up at eleven in a state of mental exaltation. He feels like getting out of bed and walking about his room, or relieves his mind by writing poetry; this is the only thing that will enable him to go to sleep again. I have some very curious specimens of this "grippe poetry" in my possession. The irritability of temper I have referred to is beyond the control of the patient, although he is fully aware of it; this is part of a hysterical condition, and, under slight exertion or emotion, a condition of hysterical aphonia may be developed, even in men. Then, again, the patient is very much disturbed by all kinds of rhythmical noises, especially at the seashore, where the "one, two, three" of the breakers nearly drives him out of his senses. Even if he can not hear them, he is conscious of annoyance from the rhythmical repetition of the waves, and this will make him extremely nervous, so that he can not sleep. The rapid succession of the trolley-car bells is also very annoying, and I have had patients who were driven out of the city by these noises.

The treatment of the chronic grippe is by alterative tonics. Buchu may be given as a mild diuretic. If there is sleeplessness, bromides are useful. All the coal-tar preparations are bad. Of the narcotics, the best is hyoscine in small doses; as a tonic, strychnine in considerable doses, beginning with gr. ½ up to gr. ½, three or four times a day. A change of climate is advisable, and the best I have found is a moderately high place, where there is plenty of oxygen with absence of noise. This is necessary to obtain rest for the mind and body. Mineral waters are valuable, and I found at Bedford great advantage from the use of the water, but there is a spring at Swiftwater, near Pocono, which I consider even better.

The wine of coca is especially useful, when the patient begins to exercise, as a "pick-me-up." I came across, the other day, a sample, of wine of coca made by the Columbia Chemical Company, of Washington city, which I found very much better than any I had previously met with, as it gave much satisfaction in the cases for which I ordered it. Where the patient must keep at his work the coca is a valuable remedy, as in the case of a preacher who has not sufficient strength to go through with his sermon without some such aid.

A Brief Study of Some Ancient Epidemics and their Relation to Influenza, with Notes on the Epidemic of 1893-'94, and Recent Methods of Treatment, was the title of a paper, prepared by Dr. Roland G. Curtin and Dr. Edward W. Wayson, as follows:

The question of the identity of the cases of excessive sweating seen frequently in the last four years with influenza is scarcely open to dispute; since, in the cases observed, either the initial symptoms were those of influenza or the sweating was evidently a sequel to a well-marked influenzal attack. All influenza, as a rule, was marked by relaxation of the skin, after the initial period and the subsidence of the earlier symptoms, and this often continued in a mild form (sweating on slight exertion, sweating when in bed, and on slight exposure to cold) for days and weeks. But the cases directly under consideration were marked by such excessive relaxation, and so entirely different from any previously observed in any other disease (except, possibly, in rare cases of convalescence from malarial and rheumatic disease, from which latter they differed in the odor of the perspiration), that they could not but strike the observer as unique.

We might add that since the epidemic sweating in phthisis

has been much aggravated, as well as in other diseases. This may be explained as a condition like the other general catarrhal conditions, a hydrorrhoa, or what might be termed, for the want of a better name, a cutaneous catarrh of the sudoriferous glands.

In the early epidemic of 1889-'90 a number of cases were observed in which there was this tendency to a remarkable degree, continuing for weeks, without emaciation or exhaustion or induced anæmia. These cases often perspired to such a degree that in cold rooms they seemed enveloped in steam, and at times, as they were observed in bed, the ear which was uppermost and the corresponding hollow of the cheek were often full of water. At times the sweat extended into the mattress, and from below upward the moisture would outline the form of the patient on the coverlid.

In one case this condition lasted one week; in another, four weeks; in another, three months; in others, five months; and in two, six months; and one case, affected a year ago, even now on slight exposure to cold continues to sweat profusely.

Many practitioners alluded in conversation, or in periodical medical literature, to similar cases, one writer in the South reporting an epidemic in his locality of what he termed a "sweating fever," and in the communication referred to asked information as to its nature. From the description given it was evidently something more than ordinary epidemic influenza, or simple catarrhal fever as usually observed, but resembled closely some of the cases seen by the writers in the past four years. Our cases generally began with an attack of influenza or had some of the complications and sequelæ of influenza-viz., the pulmonary or cardiac symptoms (angina pectoris, pericarditis, and heart failure), or affections of the peripheral nerves of one or both arms, rheumatoid pains, meningitis, diarrhœa and other catarrhal affections, and insomnia. With this profuse sweating the temperature night and day was generally near the normal -often either merely a little above or below. In one case for two months perspiration continued with the temperature from a half to one degree below normal. Another case was noticed similar to the above.

It is easy to understand from what we have seen of influenza, that in different periods of an epidemic different structures may be predominantly affected-viz., an epidemic of influenza in which cardiac symptoms predominate might, under depletion and the unwise use of depressants, come to resemble the so-called "cardiac disease" of ancient times; or, where the vaso-motor nerves especially suffered, under like improper management-overheating, excessive covering, and the abuse of diaphoretics-a genuine "sweating sickness" might be produced; or the extreme sweating producing copious miliary eruption, we might with justice call it the "miliary fever." In fact, the recent epidemic has by turns exhibited the characteristics of the various disorders described and preserved to us in the writings of several ancient observers, and it may prove of some value to contrast these characteristics with those extant observations.

The following shows what symptoms and conditions were common to all the above-mentioned diseases: Epidemic; sudden in onset; beginning with chilliness or rigor; accompanied by more or less intense headache and fever; the strong were attacked rather than the weak; the comfortable classes rather than the extreme poor; all were attended by sweat of unpleasant or fætid odor; occasional varied hæmerrhages in all; vomiting or purging at times in all; meningeal and other nervous symptoms; nervous prostration and prickling pains; sudden paralysis, heart excitation, heart failure; rheumatic pains—gouty symptoms; all were infections or contagious; all had catarrhal symptoms and sudamina or other eruptions of a mili-

ary character; in all the atmospheric conditions favoring spread of the disorder were fogs and humid atmosphere; stimulants were in all beneficial; all had heart complications; sudden excessive secretion of urine and sweating came together; all were alike sensitive to cold and draughts; checked perspiration caused diarrhoa; relapses were frequent.

The mortality was light in acute influenza, heavy in all others (this can be somewhat accounted for by modern therapeutics and hygiene), and much in this respect depends upon the peculiarity of the epidemic.

The sequelæ in all were very similar; the general constitution was shaken—dropsy, consumption, heart failure, low forms of fever followed, and insanity and suicide were frequent.

A brief study of these data will show how very analogous, to say the least, were all these diseases. Certain marked peculiarities not found in other diseases generally were common to all. The most marked is sweating, so that from the descriptions which have come down to us one could see little reason why the name of "sweating sickness" might not have been applied to any of them (at least in some of their extreme and varied manifestations). The group of nervous symptoms common to all is very striking and peculiar. These diseases seem to have been all recognized as contagious or infectious, and occurred as epidemics, and often seemed to supplant (follow or succeed) one another rapidly. The rheumatoid and gouty symptoms, the heart complications, while in some more prominent, existed in all. The description of the cardiac disease might be applied, line for line, to some of the severer cardiac influenzal cases recently met with, and at times associated with these was sweating, as profuse and overwhelming as that described in the "sweating sickness" of antiquity-lacking only its extreme malignancy.

The sequelæ seem to closely resemble each other in all, and the atmospheric conditions—fogs and rain, and a warm, moist, wet state of weather—seem to have in all been exciting causes.

We are almost forced to the conclusion that if not identically the same, these diseases belong to the same group or family, and are intimately correlated. They seem to have preceded, replaced, or followed each other in close succession through quite an extended period, or prevailed in different countries almost simultaneously, at times seeming to be conveyed by contagion or infection. Of their real origin we have no more accurate knowledge to-day than our forefathers had, but it seems a reasonable and probable deduction that there exists almost constantly in the world a form of influenza (generally transient and mild) known to us as the cold we "catch" under various atmospheric causes, which under vicious atmospheric conditions and climatic variations is capable of developing in one or another direction-and so into the various forms which we have been considering. If not all the same in origin, when once their microbic cause is really isolated and identified beyond a doubt, it will in all probability be found to be but varying forms and outgrowths of the same germ, or that varying germs exist (as in other cases is already recognized) of similar influence, causing those different diseases which may be considered as but malignant varieties of that influenza with which the world is at present so unpleasantly familiar.

The Epidemic of Influenza observed in Philadelphia during the Present Year (1893-'94).—During the years of influenzal epidemic disease since its appearance in 1889, its variations in intensity may be summed up roughly as follows:

1889-'90, very severe and fatal.

1890-'91, mild.

1891-'92, marked severity.

1892-'93, mild.

1893-'94, very marked, but not so widespread and fatal as in 1889-'90.

From this it will be seen that every other year it has been severe. The two winters when it assumed a milder form were of the five the most severe in temperature—1890-'91 having an early cold December which seemed to throw its epidemic outbreak toward the spring, 1892-'93 being continuously cold—the epidemic outbreak seeming to be worse when favored by a mild fall and early winter and great and frequent changes. This past winter the outbreak began somewhat early, about the middle of December, the usual number of isolated cases having occurred through the autumn. A certain amount of the year's outbreak seemed due to visitors returning from Chicago, where it prevailed in a mild form.

The pulmonary attacks seemed milder, though grippe lung was not infrequent. The expectoration was more inclined to be purulent. Even among the aged the fatality was light; one of the authors encountered seventeen cases with but one death, and that in a case complicated with pleurisy and effusion and catarrhal nephritis. Of the sixteen recoveries, some of the ages were eighty-six, eighty-two, seventy-eight, seventy-four, sixty-eight, and sixty-four years. The constitutional symptoms did not end by crisis, but continued some time after the local symptoms had subsided.

Diseases other than influenza have shown less of the influenzal stamp than in previous winters, but the traces of the epidemic were still visible when looked for. Considerable vertigo, alternate creeps and sweats, rheumatic pains in the limbs, insomnia, and occipital headache accompanied disorders where such symptoms are not ordinarily met. Temperature ranged lower, on the whole, than in past years. In bowel catarrhs much colitis (with gelatinous froth, with or without blood) was frequent.

The vertigo was sometimes transient, but often very persistent; change of posture induced it—throwing back the head, looking to right or left—sometimes such movements of the head even produced insensibility. This vertigo was often persistent; in one case for a year, being worse on exposure to cold, and finally disappeared with an attack of pulmonary catarrh.

Many cases of stiffn:ss and pain in the back of the neck occurred during this winter's epidemic, some with considerable fever. Constipation occurred in almost all prolonged cases of influenza, was obstinate, and marked peculiarly by a tendency to "throbbing in the bowels." This constipation was not due to hardened faces or seanty mucous secretion, but rather to an imperfect power in the muscles of the bowels, the expulsive mechanism, or both.

During the mild weather of the winter catarrhal diarrhœas were more common, associated often with vomiting, which was an unusually frequent symptom during the entire season; while during the cold spells pneumonia was most frequent.

In the treatment of influenza some changes have occurred. Some progress must be made in the management of a disease so long and constantly present with us. Not only do our necessities lead us to employ new measures, but diseases themselves change, and influenza is not an exception to this rule. If any general and marked change in the behavior of the disease has occurred it has been in the manifestation of a greater susceptibility on its part to the action of old remedies and time honored measures. In fact, there has been a revival of a number of old-time remedies which have been for a score of years discarded as useless, and which now in our epidemic experience lead us to conjecture that our predecessors were not such fools as we supposed.

New remedies, too, which were unknown to the world in

its older epidemics of influenza have been used with advantage, but in general the tendency has been to treat influenza and its sequelæ on the old lines of treatment, and with far more success than in the years since 1889, and we think that this tendency has gradually increased since that year.

For acute influenza, the salicylates and salicin still hold their popularity, which only increases with time and use, especially since we have in the market the pure salicylates of Merck and others, which certainly do not depress the system as did the crude article formerly used; phenacetine combined with these still holds its popularity in early stages, while for the cough in the bronchial form codeine is more and more used in small doses.

For the marked initial chill, spirit. æth. nit. with spirit. æth. comp. and chloric ether afford a valuable aid, and when these fail to arrest the often convulsive movements and restore the overwhelmed centers, amyl nitrite and nitroglycerin have often proved successful. Opium in the form of onset accompanied by severe pain has given far better results than in former years, with apparently no bad effects. Terebene, turpentine, oil of sandal, and oil of cubebs, as expectorants, and ammonium chloride in the later stages have been relied on; but for the persistent tickling, pharyngeal, laryngeal, and tracheal cough all remedies administered have often failed, but immediate success has been met with by employing a spray of liquid albolene and menthol, five grains to the ounce or more.

Where the grippe lung with its pseudo-pneumonic physical signs made its appearance, counter-irritation by mustard has seemed best. The pleurisies, by the way, which have been encountered this winter were almost invariably plastic and subsided readily on counter-irritation and salicylates.

The purely gastric influenza was treated by cocaine, gr.  $\frac{1}{12}$  in 3 ij of aqua chloroformi, as frequently as every hour, while the diarrheal form was managed readily in most cases by bismuth and opium, cocaine being added where vomiting continued, and in the obstinate cases, and in fact in all the cases which seemed severe at the onset; the bowels were daily flushed out with a one-per-cent. solution of creolin or boric acid. The effect of this was often marvelous, especially in cases attended by high fever, where the subsidence of temperature was almost immediate.

For the resulting prostration and loss of appetite, full doses, two drachms, of bitter tinctures, with full doses of strychnine were given; sometimes caffeine was added. Alcohol, cod-liver oil, hypophosphites, iron, and malt still hold their own, and seem the best known agents for the repair of wrecked and ruined constitutions. Opium has been found to be the most useful drug for the meningeal irritation, or mild or threatened meningitis. As to the treatment of the profuse and protracted sweating, we might as well say that after trying all recommended remedies, all equally failed of satisfactory results. Fair trial has been made of the following remedies: Atropine and belladonna, quinine and sulphuric and camphoric acids, agaracine, picrotoxine, and ergot; small doses of jaborandi seemed to do a little good; also alcohol in moderate quantities; also sage tea and boneset. Externally, alcohol and alum were of some use; internally alum failed. The power of the vaso-motor nerves seemed often so impaired that remedies had little or no effect.

Some Observations on Influenzal Neuritis.—Dr. Edward W. Watson read the following paper:

The field of influenza is almost inexhaustible. Some portions of it have received far more attention than others. If any part can be said to have been neglected it seems to be that of neuritis, in which we have often the most notable failures, and in which also there possibly lies concealed the secret of its pathology and the clew to its mystery. The different nerve affections of this disease might, if we chose, be divided into three main divisions—general nerve irritation, local functional disturbances, and local neuritis. We might consider the general aching and pain which marks the onset as the first. Functional neuroses may be met with at any period of an attack, but localized neuritides are rather sequelæ than early symptoms.

Now, the main question at issue is, whether in a localized neuritis the peculiar process gains special access to the separate nerves, or even to the nervous system generally; or whether in all influenza, as shown by its initial symptoms, the nervous system is always the seat of such process, though in so benign a degree as to escape notice; or, as a third view, whether while the nervous system is always invaded the nerves of organic life are not generally the principal sufferers, and those of voluntary motion are least and so escape notice.

We should premise that influenza, even in its acute epidemic form, is in all probability a much longer disease than is generally supposed. Early recoveries from pulmonary and abdominal forms are such only in seeming, as shown by the lingering character of the recovery, and the long period during which tonics and stimulants often fail to overcome the exhaustion and inertia. Further, in general, when recovery from acute disease sets in, the whole world brightens to the convalescent, sleep restores, food nourishes, and tonics tone; but after acute influenza there is a long period of semi-recovery—a lethargy of the system in which remedies fail to act.

Now, if in such a case of supposed convalescence exertion, exposure, anxiety are endured, we have, if early in the case, a so-called relapse, or more properly a recurrence in some new organ or structure, generally internal; but if later in the convalescence, we are more likely to have an external peripheral neuritis. A central neuritis may at times occur, as in the unfortunately frequent heart failures; but more commonly if walking has been excessive we find a sciatica, or an extension of the disease in the line of the sciatic to the calf, heel, or toe. When the arms have been overstrained in gymnastics, reaching, lifting, driving, we find a brachial neuritis-generally descending from the shoulder. These attacks should be discriminated from those muscular pains which appear much earlier in muscles in the neighborhood of organs affected by influenzal catarrhs, as the trifacial in coryza, the region of the neck in catarrhal pharyngitis, lumbar pains in renal catarrh, epigastric pain after gastritis, etc.

Of the external neuritides the brachial is the most common. This occurred in nearly half of our cases; then in order of frequency came the intercostal, sciatic, lumbar, epigastric, cervical, lower abdominal. The onset of the brachial attack is generally sudden, and often at the first the disease seems reluctant to locate, the pains radiating in the neck and thorax, axilla, and down the arm; soon, however, the painful point will be found quite fixed on the anterior aspect of the head of the humerus (shoulder). Associated with the pain come numbness and tingling in the course of the nerve, and the shifting character of the numbness, etc., from radial to ulnar distribution, or vice versa, shows how intermittent is the obstruction and interference with the nerve current (action). These shifting sensations are by no means to be taken as indicating that the active process has extended to the fingers, but that where located it obstructs or interferes with certain nerve fibers distributed to the fingers.

The actual discernible alteration in the course of the nerve is found most frequently in the region of the biceps, though painful points can at times be made out at and below the elbow. The biceps, however, most frequently in protracted cases hardens with a doughy hardness and enlarges. In unfavorable cases it afterward wastes very considerably. Similar wasting has been observed in other regions where other nerves are in like manner affected. We are inclined to believe that if proper care be early taken the condition tends to somewhat rapid recovery, but when the arm is used to any extent, and where with this there exists a gouty history or a gouty inheritance, under undue effort, and imperfect nerve supply, the muscles go into a state of tonic spasm or contraction and the nerve exhausted in its efforts to transmit the force demanded becomes locally still more involved; rarely an eruption of shingles occurs in the course of the affected nerves.

We may as well admit that this condition is somewhat beyond direct and positive therapeutic aid; how serious the condition of the nerve may at times become has been of late shown by careful post-mortem examination. How very hopeless the restoration of function may be, is shown in the series of cases reported by Dr. Ferguson, of Toronto, in the Medical News of January 6th of this year (1894), for although no mention is made by him of the fact that his cases were any of them of influenzal origin, though he mentions in one case that influenza had preceded, we think that at least three of the five bear evident marks of being due to that cause. Again, a study of the behavior of these diseased nerves under certain circumstances tends to throw a partial light into the general gloom. Again and again after applying the interrupted current the pain has been rapidly relieved, but within a few hours a more violent attack has occurred in a more important (and serious) locality -from the arm to the lumbar spine, to the cervical region, to the præcordial region, to the other arm; sometimes exhaustion and faintness; sometimes intermittent pulse has been noticed. The same experience has been encountered in the employment of massage of the affected arm, while in other cases in later stages, or in the same case later in its course, both agents have been of the greatest service and conduced to permanent recovery. In three cases long localized pain in the epigastric and abdominal regions has yielded at once and permanently to one short application of the battery.

It would be well also to notice those cases of intra-thoracic and intra-abdominal neuritis attended with much more threatening symptoms, where change of position leads to failure of pulse and loss of consciousness, or to profound nausea, or to respiratory failure, which as they gradually recover seem to do so by an exodus of the morbid condition from within to without: where an emerging neuritis of arm or leg seems the surest harbinger of escape from a fatal illness. The influenzal process seeming to traverse deep-seated and vitally important centers and nerve trunks and emerge to those of less vital moment. This has been a somewhat common termination of many cases of apparent neurasthenia, which should, however, be discriminated from the neurasthenia with which we have of late years -before the influenza epidemic-become so unfortunately familiar, for between them there lies a great difference. In either case the patient is neurasthenic, but has arrived at that condition by quite a different road. The typical neurasthenic has exhausted centers, and we believe may have injured nerve trunks even, by excessive and prolonged exertion or sudden overstrain. The influenzal neurasthenic has the nerve centers, perhaps the communicating nerve trunks, certainly occupied and rendered useless for a longer or a shorter time by a progressing disease. In the former case it is but necessary to accumulate force and cause its conveyance to mechanism which we put in the best possible order; while in the latter case we must await the disappearance of the disease before we can hope for improvement; this we think supplies the reason for the behavior of the patient under massage and elecIn summing up therapeutic results, we can say that rest is an absolute necessity; that electricity has benefited many cases, generally ones of long standing, but has injured, at least for a time, many early cases; and that massage, though less powerful for good, has been only less powerful for evil; while counter-irritation has been disappointing, and repeated blistering has repeatedly failed.

In the early days of the attack heat has been often valuable, where the whole limb could be enveloped in moist heat as by fomentation, or swathed in hot flannels, or placed in hot water. But no drug has given reliable results. When improvement has been most pronounced, then relapse and disappointment have been most certain. If to this sweeping statement there be any exception, it is in favor of arsenic in very small doses frequently repeated. Of general systemic treatment, such as with strychnine and phosphorus, quinine and alcohol, and cod-liver oil, we are not speaking-these may generally benefit the patient, appetite may increase with assimilation, strength and the general appearance of health may return, but the arm or leg be much the same. Mercuric bichloride, iodides, and bromides have given no results; salicylates and salicin have failed to relieve-they may have prevented. Morphine pushed continuously has seemed to shorten the attack in many cases if given early, possibly by enforcing that rest which is so vitally important to cure; atropine, which controls some of the manifestations of nerve disorder-as the chilliness, excessive sweating, and the pulmonary conditions-is a failure in the neuritis under consideration. Hypodermics of atropine in the painful points or into the affected muscles (biceps itself) have given no good results. Locally, belladonna, menthol, ichthyol, and mercurial ointment have been used with apparent benefit. But viewed in the most cheerful light treatment is unsatisfactory, and prevention is better than cure. Preventionif the ideas expressed in this paper are correct-by early and continuous rest continued long enough to allow the system to react and the disease to naturally terminate; and when exercise is permitted, with such restriction as to avoid tire, general or local, and this will require such confidence on the part of the patient, and such an education on his or her part also, that it will, I fear, be long before the disease is banished by preventve measures.

The treatment of an internal neuritis of a nerve supplying a vital organ resolves itself into a treatment, so far as possible, of the organ involved. To take one case as an illustrationthe stomach. All are familiar with the fact that digestive difficulties have been unusually frequent of late; they have taken the form of delayed digestion, with emesis, pyrosis, and eructations. In the majority of these we have found the difficulty to culminate at night, to be least in the early morning. All of them, if carefully questioned, will give a history of influenza as a starting-point, generally influenza of the gastric form, though perhaps not recognized as such by the patient; they go back to an attack of chilliness and fever with vomiting, fever with loss of appetite, fever with diarrhea. Following these there will often be a history of gastric pains excited by food; often a distinct account of a peculiar pain or mild gastric pang coming on at short intervals after eating, and peculiar in that it starts in the region of the pylorus and travels in a wave or thrill in the direction of the greater curvature from right to left, dying out gradually as it travels, only to be followed by a succession of such pains. As these pains diminish with days and weeks the patient discovers that he has dyspepsia, and, if appetite returns, he begins soon to suffer after meals in a different way with acute indigestion. After a time the gastric soreness is almost continuous, and nights and days are passed in great distress, and speedily weakness and emaciation occur. Now, these cases

seem to be due, judging by analogy, to a condition of the pneumogastries or splanchnies similar to what we have been noticing in external nerves—a long-continued state of diminished action of the gastric muscles, owing to their supplying nerves having been occluded or interfered with by influenzal disease.

Those who have attempted to relieve these cases (which show no evidences of dilatation and rarely of any gastric catarrh) will bear witness to the general uselessness of the old lines of treatment and the new ones as well. They resemble cases of dilated stomach with pyloric obstruction, but are most probably atonic stomachs with normal pylori, in which the force of contraction is insufficient to expel the digested food, or where the almost unknown nervous mechanism of the pylorus is in some way at fault.

When this condition has become aggravated and distress is constant, washing out the stomach will undoubtedly give reliefbut acids, alkalies and bitters, pepsin and peptonized foods avail little. From careful observation of the general condition. the observer must be led to conclude that a defective innervation and consequent painful and feeble action of the stomach is the real difficulty, and that the retention of food too long leads to the formation of digestive products toxic to the economy and irritant to the organ itself. Intense irritability is often shown by emesis where the matter ejected seems quite normal; faulty innervation by the cases when digestion can go on normally for days in the recumbent position, but where the patient, on assuming the upright or sitting posture, invariably vomits after a definite period of time-half an hour or an hour. That increased irritability is one cause of the delay and distress is shown by the character of the only drugs which seem to afford relief. Chloroform, cocaine, bismuth, alcohol, and the bromides-these, especially the latter, will in many cases restore appetite, relieve distress, and banish indigestion; but when they fail we seem left with but one alternative other than washing out the stomach-viz., to give the organ as long and continuous a rest in the twenty-four hours as is possible, in order that it may store up power enough and free itself. This gives immediate relief and so is willingly pursued by the patient.

As a formulated plan of treatment, it is best to begin with twenty-four hours of semi-starvation, interdicting all food except a gill of hot milk three times in the first day; on the next day ordinary diet can be given in full amount at the morning and noon meals, but after 2 P. M. nothing until the next morning at breakfast. In a few days the appetite will accommodate itself to the circumstances. The stomach, relieved and free from pain, does its work in better time and manner, and emaciation ceases and weight is rapidly regained. The weight of the patient should be carefully taken at intervals of three days, and when there is no more increase, where further increase of weight is desirable, then more food must be given; and first a return to some form of evening meal should be tried. Milk or a farinaceous food with milk is best borne, and if all is well the patient can return to his former habits in regard to eating and is cured. If, however, as is often the case, this can not be done, the extra food may be given in the forenoon-i.e., breakfast at 7 A. M. or earlier; lunch at 11 A. M.; dinner at 2 P. M.; in this way as much food can be taken as ever, but without dis-

When from the beginning the distress has been absent at night and severe during the day—as, for instance, where the most serious suffering is experienced after breakfast—breakfast itself must be omitted or reduced to a cup of milk, while dinner and supper are taken as usual, the necessity being for some period of rest continuously in the twenty-four hours of from fourteen to sixteen hours. The lighter cases, where the mid-

day meal alone is followed by indigestion, can generally be reached by bromides and a bitter, or by omitting the mid-day meal altogether, even adding additional food at bedtime if the scales show no gain.

How successful this plan of treatment is, how much relief it affords, and how notably the patients gain in weight and spirits, will be realized by any one who will try it. Crude enforced starvation has always been one of the main remedies of empirics and charlatans in dealing with indigestion, but in the method we have described we believe it to be scientific and valuable.

Cases illustrating the success of this plan, which for want of a better name we might term "digestive rest," could be given in considerable numbers were it desirable to add to the length of this paper; let it be sufficient to say that in genuine post-influenzal dyspepsia the writer has met with very few failures save where undoubtedly the directions were not followed. Where the case is severe and the patient can be induced to give the plan a three-days' trial, his own relief will be a sufficient inducement to pursue it as long as is necessary.

Rest, then, of all remedies seems most fitted for the relief of influenza from its onset to its remotest sequel. There seems always to be a deficiency somewhere or other in the power of sustaining voluntary and involuntary exertion, and a tendency to aggravation or relapse on exhaustion. Did time permit, a study might be made from this point of view of other post influenzal conditions, showing, for instance, how the peculiar catarrh of the liver is best treated by relieving the liver of work in the shape of foods it can not manage and of cholagogues it can not endure; how the influenzal affection of the ocular muscles, which baffles the best-meant efforts of relief with lenses, yields speedily to darkness and disuse of vision; and lastly, how the mania and delusions of influenza are combated most hopefully by those remedies and means which, like opium, enforce sleep continuously for considerable periods of time.

Dr. Judson Daland said: Dr. Curtin's remarks with reference to the sweating sickness were of special interest to me, and one readily understands why the name was applied to this disease in olden times. His descriptions of epidemics that occurred long ago were well made.

Dr. Curtin's wide knowledge and extensive experience make anything that he says in regard to the therapy of this affection of great importance. With regard to the "grippe lung" to which he refers, this affection has for a number of years attracted my attention, particularly from a diagnostic point of view. The physical signs in these cases often vary from day to day with extraordinary rapidity—in fact, with such rapidity as to make one doubtful of the correctness of the first diagnosis. The pathological examinations show a mixed condition of bronchitis, catarrhal pneumonia, and collapse. These lesions occurring in different parts of both lungs, and varying with such extraordinary rapidity, suggest a distinctive nervous origin, and there is probably an interference with the nerve supply of the lung.

I did not hear Dr. Curtin mention the use of strychnine and alcohol in the treatment of the general disease. The benefit derived from the use of these agents during the height of the disease is very great, and they are practically the chief remedies to be relied on. The use of the salicylate of sodium and phenacetine has given me the results which he has mentioned.

Regarding the suggestion of Dr. Seiler that this affection be called American grippe, I should say that although I have not studied European grippe, the descriptions which I have read, and the numerous conversations that I have had with Continental physicians, have failed to convince me of any essential difference in the disease as we see it here. I therefore think it un-

wise to add another to the various synonyms for influenza, which name is the one to be preferred.

Dr. Seiler also states that the chief cause of death is hæmorrhage from the mucous membrane. In my experience the chief cause of death has been the pulmonary complication. With regard to the use of benzoate of sodium, I do not think that the favorable result described could be expected in many cases as seen in general practice.

With regard to the effect of quinine in the production of insanity and other mental disturbance in influenza, although I have seen many cases of influenza, most of which have received quinine, I have yet to see a case in which the causal relation between the mental condition and the use of quinine could be established.

Dr. J. Solis-Cohen said: I came here to listen, and have not prepared myself to take part in the discussion. I remember the initial papers of Dr. Glasgow and of Dr. Seiler very well, but while Dr. Glasgow named the disease "it," he distinctly stated that in his reading he could not find anything that resembled it except the old records of influenza. This was a very acute observation, made, as it was, three or four years before the epidemic became pronounced. My own earlier cases were treated exactly as Dr. Glasgow had recommended-that is, with benzoate of sodium-and I do not now know of any treatment that acts better than putting the patient at rest, giving benzoate of sodium in ten-grain doses every hour or few hours until the kidneys are acting freely, and then continuing it less frequently. Strychnine, acting as it does on the terminal nerve fibers, is of great service, for the disease exerts its baneful influence markedly on the terminal nerve fibers of the structures concerned in the nutritory and circulatory systems.

The class of cases that I have seen suggests that this disease is largely a disease of the lymph and circulatory systems. We know that the nasal lymphatics are in close connection with the subdural space, and in many of the cases where the nasal symptoms are severe, we have severe meningitis and those conditions which render the patient despondent, as a direct sequence by continuity of structure. The profound impression on the nutrition shows also that the lymph system is very much affected.

In the history of previous epidemics of this disease marked reference has been made to different varieties, such as the pulmonary, gastro-intestinal, and other forms of influenza, and I have asked a number of my friends in general practice whether they had observed in recent epidemics as many miscarriages as had been described in previous epidemics. I found that, with the exception of the epidemic of 1889-'90, there had not been so many noted.

Another reason for regarding this as largely a disease of the lymphatic system is the occurrence of the affection of the throat described by Dr. Seiler: that peculiar puffy condition which looks apparently like ædema of the larynx and ædema of the palate. When you incise these parts, however, you do not get a serous fluid. Sometimes you have blood and sometimes a nucoid material or lymph, which may exude in long, continuous strands.

Now, as regards the use of quinine in influenza, I have often been asked what can be done to prevent the occurrence of the disease in unaffected members of a family in which it has appeared. I have always advised the use of quinine in ten to fifteen-grain doses early in the morning. I am satisfied that large doses often act as a preventive, and that in these cases the quinine does not so readily produce the ordinary symptoms of cinchonism.

In using strychnine I think that the best preparation is the arseniate, which I give in the granules dosimétriques of Burg-

graeve, containing half a milligramme, or about a one hundred and twenty-fifth of a grain. The patient takes three to six or more granules a day, and continues it for a month or two. In that way many of the sequelæ can be prevented.

Dr. Frank Woodbury said: I look upon influenza as essentially an intoxication. In Europe epidemic influenza, or the grippe, is now pretty well accepted as having for its cause the bacillus of Pfeiffer. It is stated that pure cultures of this bacillus will reproduce the disease in animals, thus fulfilling the requirements of a specific, infectious germ. Pfeiffer's bacillus, however, is, like the tubercle bacillus, often found in association with the staphylococcus and the streptococcus and other bacteria of suppuration, thus accounting for the organic inflammations. As the influenza bacillus is not found in the blood, it probably acts by its products principally upon the nervous system.

It is very possible that the germ of influenza may have suffered some modification in its development and pathogenic effects, owing to different climatic conditions in this country from those of Europe, so that we should not be surprised to find modifications in the course of the American disease, such as Dr. Seiler insists upon. That there is any ætiological difference between the two kinds of epidemic influenza has not been suspected; possibly Dr. Seiler's observations may have been upon an entirely distinct disease.

The portal entrance of the poison into the system is worth considering. In most cases the culture ground of the bacillus is probably located in the upper air-passages, and I am inclined to think that the tonsils and the naso-pharynx are the special points of election. In others the bronchial mucous membrane is most affected, while in other cases the gastro-intestinal canal is the particular place of development. It has occurred to me that, just as in the administration of morphine hypodermically, the effects of the drug are most marked if injected in the neighborhood of the seat of the pain, although we know that the drug acts through the general circulation, in a similar way the well-recognized varieties of influenza may be connected with the several culture-fields of the bacillus, the toxine acting most virulently in its immediate neighborhood, producing cerebral, gastro-intestinal, or broncho-pulmonary phenomena, which have been alluded to.

This leads me to speak of the prophylaxis of influenza. I can indorse what Dr. Cohen has said with reference to quinine. I employ it as much for antiseptic and prophylactic purposes as for its tonic effects. The mouth and throat should be kept clean by the use of mild antiseptics, and the naso-pharynx by the use of Seiler's pastilles or Dobell's solution, and the throat carefully watched. There is no question in my mind that the disease is contagious; when it appears in one member of the family others are liable to be affected. This has been established by the local epidemic which was reported by Dr. J. W. White and Dr. Simes to this society several years ago. It will be remembered as the case of Dr. S. S. White, who died of influenza in Paris, and whose body was brought to his home in this city, whereupon a number of persons who were in the room when the casket was opened contracted the disease, although there were no other cases in the city at the time.

In the few cases where I have used benzoate of sodium I have been pleased with the result. I have especially relied on strychnine, given in the acid solution of the hypophosphites according to the formula of Dr. Gerhard. The strychnine is given in doses of a thirty-second of a grain, gradually increased. With this I have used coca, and in regulating the diet I have found the juice of fresh fruits, such as the orange and pineapple, to be of service in assisting the weakened digestion. These juices have been shown to have considerable peptonizing power over albuminoids, and the salts they contain possess diu- 1 ary symptoms due to poisons generated during the disease.

retic and antiscorbutic effects which are useful in improving the condition of the blood.

Dr. WILLIAM S. STEWART said: There is a great variety in the manifestations of influenza, but the ordinary influenza which is so common in this country is certainly very contagious. The influenza of la grippe is a different affection from the ordinary influenza. I do not think that it is particularly contagious. I have seen grave and serious cases where no other member of the family was affected.

In regard to treatment, I wish to say a word as to the bromides, particularly in those cerebral cases that would be liable to be affected by quinine. I have combined the bromides with gelsemium with great benefit. In some of these cases if you give quinine you only intensify the pain and delirium. When the cerebral suffering is relieved then it is important to give iron, quinine, and strychnine, and it may be aromatic spirit of ammonia, to tone up the system and to overcome the heart-depressing effect of the disease.

Dr. Solis-Cohen said: I am pleased to note that Dr. Curtin and Dr. Watson in some of their conclusions confirm those which I published in an article upon Catarrhal Fever, contributed to the Medical and Surgical Reporter, October 29, 1887some time previous, therefore, to the enlarged experience which we now have. One point which I endeavored to make was that influenza is always with us, but that except in times of widespread epidemics it was only recognized as such by those who, through teaching or early experience, had had their attention specially directed to it. This is, I think, an important matter and will bear emphasizing.

I am also glad to note that experience has confirmed the usefulness of the salicylates in this disease. In the cases which came under my observation in 1885, 1886, and 1887, and upon which the paper referred to was based, I had found cinchonidine salicylate apparently curative, and so reported. I have more recently used sodium benzoate in early cases with much benefit, especially those in which there was a tendency to suppression or great diminution of urine or which exhibited severe pains in the loins.

The value of strychnine in the prevention and treatment of the distressing sequelæ can not be overestimated. The drug should be given in small doses frequently repeated.

Dr. Curtin and Dr. Watson emphasize the great sweating; I have been much impressed with this in my own experience. I remember one case in an old man, in 1889, in which profuse sweating and subnormal temperature were the only objective symptoms of the disease. This continued for two weeks, and I am satisfied that if that patient had not been put to bed and kept there with the external application of heat and with the administration of hot drinks, of cocaine and restoratives, he would have died, almost without realizing that he was sick. He had complained merely of discomfort in the throat, nothing to account for the symptom being discernible on examination.

Dr. Samuel Wolfe said: I have observed a considerable number of cases of the intestinal form in which the symptoms resembled those of dysentery, but the affection yielded to the same treatment as did other forms of grippe. The affection of the nervous system is a very large element in the disease, both in its onset and in its sequelæ. The variability of the seat of attack shows this to be the case. The sequelæ-insanity, meningitis, and neuritis-point to a secondary poison affecting the nervous system. Many chronic nervous affections date back to an attack of grippe.

Influenza is comparable to diphtheria, inasmuch as we have the acute symptoms due to primary poisoning and the secondI would take exception to the statement that influenza is similar to the ordinary colds which we always have with us. The best treatment for an ordinary cold is trying to shake it off; this in influenza would lead to prolonged convalescence or sequelæ. The most valuable element in the treatment of influenza is rest. The patient can do better without any drug than without rest. This rest should be prolonged until the patient can make efforts without tire. This difference alone proves that influenza is dissimilar to an ordinary cold.

As to therapeutics, I believe that quinine is one of the best remedies, not in one large dose, but in smaller doses frequently repeated (four grains every two hours) until some cinchonism is produced, and this should be brought about in the early part of the day. I would rather do without any other drug than give up quinine. In the intestinal form, salol is a valuable remedy and may be combined with quinine. The neuritis is to be treated like other forms of neuritis. Hypodermic injections of cocaine (in doses of from one eighth to one half grain) near the seat of pain, and repeated twice in the twenty-four hours, relieve the pain not only for a short time but permanently, and bring about an earlier convalescence.

Dr. Solis-Cohen said: Replying to Dr. Wolfe, I did not mean to say, and I trust I did not say, that influenza is the same as an ordinary cold, but I wish to emphasize the fact that influenza is not merely an epidemic disease, that it is seen every year and every month, and that many cases of influenza are ordinarily mistaken for "colds," for acute catarrhs of nose, throat, bronchi, stomach, or intestines, and even in some instances for typhoid fever and for rheumatism. Influenza is at times the easiest and at other times the most difficult disease to recognize. The opinion of those who have most closely studied the affection is that it is a disease of intoxication, due to a specific poison, depressing the organic nervous system. This poison may be the result of the development of a microbe, but as yet this microbe has not been definitely proved to exist. In consequence of the organic nervous depression we have, for example, labored respiration from pneumogastric failure even where the lung can not be shown to be much involved. The general depression and the severity of symptoms, not to be accounted for by signs discoverable upon physical examination, differentiate the disease from ordinary "colds." Besides this disproportion of symptoms to signs, there are a number of minor points-for example, general soreness or aching, or localized pain, such as infra-orbital or supra-orbital neuralgia, and the neurotic character of many symptoms, such as dyspnea and cough, and cutaneous hyperæsthesia. The general course of the affection is likewise significant. It is rarely confined to a single physiologic apparatus, but beginning as a coryza or a tonsillitis may end as a diarrhea, or beginning with gastric symptoms terminate as a broncho-pneumonia or a laryn-

When the true nature of cases is not recognized and they are allowed to go untreated, or rest is not part of the treatment, serious sequelæ are often developed. It was the observation of such sequelæ, and especially of chronic bronchopneumonia in children attending the Medical Dispensary of the Jefferson Medical College Hospital during my early years of service there, that first impressed me with the facts recorded.

Dr. Seiler said: The diversity of opinion as to symptoms and treatment lies in the fact that we indiscriminately speak of grip, influenza, and la grippe. We also speak of fever and catarrhal pneumonia. High temperature does not constitute fever. The disease consists of influration of the mucous membranes as a result of an intoxication. In American grippe, the benzoate of sodium is the best remedy. In influenza, quinine is

of service. The treatment of the sequelæ is to be guided by their character.

Dr. Curtin said: As to the effect of quinine, as stated by Dr. Seiler, I recall three cases of insanity following influenzal attacks which occurred before any treatment was instituted.

Dr. Watson said: It may be that Dr. Seiler has in mind catarrhal fever. In that affection there may be low temperature, moist tongue, and all of the symptoms which he has described.

As to antidotes, I have used benzoate of sodium in many cases, but did not get any better results than from other remedies, such as salicin and the salicylates. I have seen five cases of insanity following influenza where quinine was not used, and many cases persistently using it which did not become insane. This should be distinctly stated, lest Dr. Seiler's experience should be understood to be the usual one.

### Miscellany.

American and English Sanitation.—The Lancet for March 10th, commenting on a certain embarrassment of the International Sanitary Conference now sitting in Paris over the American delegates' expression of our national views on promiscuous emigration, says:

"In order to understand these views it is first of all necessary to realize the very large measure of autonomy or home rule enjoyed by the various States that form the Union. The States are very jealous of their rights, and have been particularly reluctant to hand over to the central authority-i, e., the Federal Government—any right to interfere with their sanitary arrangements. Each State has its special laws of health and its own sanitary authority. The Federal Government can not exercise any control over these State sanitary authorities. In some States the public health laws are good and well administered, in others this is far from being the case. There is therefore a total want of uniformity. Those States that have a sea border do not agree with one another as to what kind of quarantine, if any, should be imposed on ships entering their ports. Of course, sanitary reformers have over and over again insisted that the same rules should be established in all the ports, and that such matters should not be left to the caprice of local authorities. The voice, however, of the sanitary reformers is lost amid the many other cries and political questions of the day. Nothing could be done till some urgent crisis arose which forced the whole nation to take an interest in these special and somewhat technical questions. Such a crisis occurred, fortunately, in the autumn of 1892. The action of the New York port sanitary authority in their treatment of passengers arriving from Europe caused, it will be remembered, a great outcry. It was then felt that a local authority should not be able to imperil the commerce of the whole country; also the inhumanity then displayed by a panic-stricken and incompetent local authority gave body and strength to the demand for national as opposed to State legislation. It was in consequence of this movement that at last a statute was enacted giving the Federal Government a right of control over all quarantine stations on the land and sea frontier. This was the first national sanitary law enacted in the United States. All the other public health laws have been adopted by individual States and do not apply to the nation at large. Naturally this, the first, national statute is very imperfeet and insufficient. For instance, it gives the Federal Government control only over the quarantine stations, and no authority at all over the towns or neighborhoods of the quarantine stations. If, therefore, a passenger is released from a quarantine station, the Government can no longer watch him. In England, if a suspected crew or passengers are allowed to land, instructions can be forwarded to the authorities at their places of destination to watch over them in case they should become ill. This can not be done in America; at most it could only be suggested to the sanitary authorities of the various States concerned that it would be advisable to watch such and such a passenger. Some of these authorities, especially in the Eastern States, would understand the value of such advice, and act accordingly; but in other States, especially in those in the West, this would not be appreciated, and the advice would not be followed. Therefore all control over a passenger after be has left a quarantine station is lost, however great the danger of disease importation.

"The next question is, How far can the United States afford to incur this risk? It must be recognized, first and foremost, that the water supply in a great number of American towns is bad. In England many towns bring their water from long distances, and from places where there is not much risk of contamination. In America some towns are equally well favored in this respect, but they are not as numerous as in England. Then, again, in England many towns have filtering beds to purify their water supply. Such is not the case in America. Consequently, it is felt that in the United States, especially in thickly populated districts, there are many towns where the conditions are such as to render them liable to epidemics of cholera as severe as that which afflicted the town of Hamburg. Undoubtedly the Federal Government would be very pleased to apply in America the system which has been carried out in England and in France; but it is materially impossible to attempt anything of the sort. In England there is an army of well-trained and trustworthy medical officers of health, sanitary inspectors, disinfectors, etc.; in America this machinery does not exist; nor was it created in England in a day. It has been the slow result of hard and earnest work, and England has spent more than £100,000,000 for such purposes. What is at once possible and successful in England after all these sacrificet and all this work is not possible in America, where there has been as yet no national legislation and no joint effort. Therefore the American Government is not disposed to abandon quarantine; nor will this determination be shaken by the boasting of English sanitary authorities. England, it is urged, abandoned quarantine after it had put its house in order and not before. This abandonment of quarantine is, too, of quite recent date, and does not apply to Malta, Gibraltar, and other British colonies; in other words, while approving in the abstract of English methods, the American Government has not the means of carrying them out.

"The commercial situation in America is, moreover, quite different. America lives on its internal, not on its foreign, trade. What this internal commerce is may be judged in some measure from the fact that at the end of last year there were 63,800 kilometres more of railways in the United States than in the whole of Europe put together. Then there are in America the magnificent and lengthy navigable rivers. Nothing similar exists in Europe. Now, if cholera broke out in any part of America, we should have States imposing quarantine against arrivals from other States, and cities taking measures against other cities. Each State being free to do as it chooses, and panic aiding, restrictions of all kinds would be imposed that would check and ultimately paralyze the home trade and traffic of the United States. As this interior commerce is perhaps a hundred times more important than the exterior or foreign commerce of the United States, the Government does not feel disposed to sacrifice the hundred for the sake of preserving the one. It will base its action on this fundamental principle thus: Firstly, excepting the last two epidemics, the United States have always suffered from cholera when there has been cholera in Europe; secondly, cholera has always been brought over by emigrants who were actually ill, or by the soiled personal effects belonging to emigrants. In one case an emigrant brought over clothes which he had packed up in an infected district of Sweden. He started from a European port free from cholera, landed at an American port equally free from the disease, and then traveled a considerable distance into the interior. It was only when he reached his final destination that he unpacked his clothes, and there cholera broke out three or four days after his arrival. The United States Government sanitary advisers do not fear merchandise or saloon passengers, but they urge that precautions should be taken against emigrants.

"There is no desire to interfere with traffic and to place ships in quarantine, but precautions should be enforced, if not on the American side, then at the point of departure. The latter is the solution of the difficulty which the American Government desires to submit to the European powers. In the name of humanity and of good neighborly feelings, care should be taken not to ship over to America infected clothing or persons likely to convey infectious or contagious diseases; but, if this principle does not suffice, then, even from selfish motives, the European governments should act in the manner desired. A great deal has been said about the pilgrimages to Mecca, and it has been urged that, in English ships alone, as many as twenty thousand pilgrims have been taken to Mecca in a single season; but this is nothing when compared to the four hundred thousand, or so, emigrants who yearly go over to America. This great current of humanity traveling through Europe on its way to the New World exposes Europe itself to considerable danger, and it would be to the latter's interest if these immigrants were forced to observe laws imposing cleanliness, etc., from the moment that they commence their journey. Then, when finally the emigrant reaches his ship, he is stowed away in an overcrowded steerage, where the most unsanitary conditions prevail. The pilgrims to Mecca are not worse off than the steerage passengers to America; and the sanitary regulations of the pilgrim ships will be better in themselves and better applied than are those governing the steerage passengers to America. If considerable improvement in this respect is not enforced, the European powers will be the losers, because quarantine will be imposed on ships arriving in America, and this will not only injure the passenger traffic but also the exportation of merchandise to the United States. The American Government consequently desire that steerage accommodation should be considerably improved, that care should be taken not to allow persons likely to convey disease to embark, and that all soiled personal effects should be disinfected before they are taken on

"Such, briefly and without comment, are the views, with the causes underlying them, which, we have good reason to know, are held by the United States Government."

## Sublimed Sulphur as a Topical Remedy in Diphtheria.—

In the British Medical Journal for March 3d there is an article on this subject by Professor Bäumler, of Freiburg, who dissents from Jacobi's and Oertel's unfavorable opinion of sulphur, and says:

"I was first induced to try it by the recommendation given to this local treatment by Professor von Liebermeister, in his lectures on Special Pathology and Therapeutics (Leipsic, 1885, vol. i, p. 232), where he says: 'As a local application, I generally use powdering with crude sublimed sulphur, by abundantly

applying with a thick, soft camel-hair brush the dry powder to the diseased mucous membrane. This powdering of the pharynx with sulphur is, according to circumstances, repeated every hour or every two hours, or only three or four times a day.' On the strength of several years' experience, I entirely concur with Professor Liebermeister's further remarks: 'I have the impression that by this treatment, when commenced early, I attain more than by any other which I had tried before, and that with these applications the cases, on an average, take a considerably more favorable course than without it.' I have repeatedly seen cases, in which gangrene of the uvula and part of the soft palate seemed unavoidable, take a favorable turn in a few days, the membranes becoming detached and the swelling going down, leaving much less loss of substance behind than was to be feared when first seeing the case. With less extensive disease we could frequently notice the first effects of the application to consist in a somewhat increased injection (not congestion) of the mucous membrane on the borders of the exudation, the latter becoming more sharply defined at its edges after a few applications, and then beginning to get loose and be detached.

"In the majority of fresh cases of diphtheritic sore throat, as well as of lacunar tonsillitis, two or three applications a day seemed sufficient, the patients in the meantime, when able, gargling with a weak solution of permanganate of potash, and being subjected to such general treatment as the case required (cool baths or the wet sheet, or occasionally a dose of antipyrin when there was high pyrexia, and great care as to feeding by mouth, or, if necessary, by the rectum).

"How the sulphur acts in these cases I am unable to say, and I may mention that there seems to be no particular difference in the action of sublimed or precipitated sulphur. Nor am I aware that as yet any experiments have been made with regard to the action of sulphur on the particular bacteria which cause diphtheritic and other kinds of sore throats (Loeffler's bacilli and streptococcus chiefly). But while anxious for the scientific explanation of the facts so frequently observed, we need not delay making the experience gained more generally neeful.

"The action of this remedy being a merely local one, its principal field of usefulness will be diphtheria of the fauces, where it can be applied directly and abundantly. The larynx, also, and in certain cases the upper part of the trachea, may be reached by using a curved insufflator for blowing in the powder. But no effect can, of course, be expected when the disease extends into the bronchial tubes, or when the general blood poisoning has gone beyond a certain degree, nor even locally, where extensive sloughing has already taken place in the throat, and when, in consequence thereof, rectal feeding is the only, and then mostly insufficient, means to prevent exhaustion.

"I am unable to say whether remedies which have more recently been recommended, such as pyoctanin or the peroxide of hydrogen, which has found such warm supporters in America, give even better results than the sulphur, as, especially in severe cases, I did not feel justified in foregoing the benefits of a remedy of whose efficacy I have had ample personal experience."

An Indian Medical Congress.—We learn from the Indian Medical Gasette that the proposal to have a medical congress in India was considered at a meeting of the council of the Calcutta Medical Society on January 24th, when it was decided that an Indian medical congress should be held in Calcutta at the beginning of January, 1895. The preliminary arrangements were discussed and a general plan was sketched out. It was decided that in each province local secretaries, native as

well as European, should be asked to co-operate with the Calcutta secretaries, and it was further decided that the sections into which the congress should be divided should be:

Medicine, including pathology.
 Surgery.
 Obstetrics and diseases of women and children.
 Public health.
 Legal medicine and allied subjects.

It was decided that the congress should be widely advertised, and that all medical men practicing in every part of the world, but especially in India and the East, should be invited to take part in it and submit papers to be read in the different sections.

Diiodoform.—La Presse médicale for February 24th contains an article by M. L. Maquenne in which he remarks that, owing to the strong and persistent odor of iodoform, a large number of physicians have been obliged to do away with it in their private practice. For a long time they have searched for a drug to replace it, which would produce the same effects, and without the disagreeable odor; but it has been difficult to find one with an organic combination comparable to iodoform with regard to the abundance of iodine it contains and to its physiological action. Diiodoform, which is not to be confounded with the deodorized iodoform of commerce, is entirely satisfactory in this respect. It is a definite iodide of carbon, which answers to the formula C2I4; it is derived from ethylene or olefiant gas, and should be called, according to the rules of chemical nomenclature, periodized ethylene. It will be seen that it differs from iodoform, CHIs, in containing no hydrogen and containing twice as much carbon; theoretically, it may be considered as a product of the condensation of iodoform in which two particles are united with loss of hydriodic acid. This, as well as its known physiological properties, has caused it to be commonly known as diiodoform. Its centesimal composition is extremely like that of ordinary iodoform, as will be seen by the following comparison:

Iodine	Iodoform, 96.70	Diiodoform 95*19
Carbon		4.81
Hydrogen	0.25	0.00
	100.00	100.00

The quantity of iodine is very nearly the same, exceeding greatly that contained in iodol and aristol, which are sometimes used instead of iodoform. This explains the analogy of the action of these two substances and their undisputed superiority over all other antiseptics having iodine for their base. Diiodoform is a yellow substance, almost entirely odorless in an ordinary temperature, which melts at 377.6° F., and becomes decomposed into its elements, carbon and iodine, under 392°; it is perceptibly volatile when heated, and can be sublimed. Completely insoluble in water, slightly soluble in alcohol, diiodoform is easily dissolved in carbon disulphide, in chloroform, in benzene, and in the majority of hydrocarbons, and it is deposited in the form of beautiful prismatic needles, which are pulverized for use like iodoform crystals. Diiodoform can be kept indefinitely in a dark place, but is susceptible to light. Under its influence it becomes darker and emits a slight odor somewhat like that of the hypochlorites. In order to prevent this, diiodoform, and all preparations in which it is contained, should be put into bottles colored green, yellow, or red. It is recommended also, when employing it, not to expose it too long to a bright light. If these precautions are followed, it is possible to have dressings that are strictly odorless. Experience has shown that it is well borne by the stomach, and that it is practically non-poisonous. With regard to its germicidal action, it is the same as that of iodoform-i, e, rather weak.

Diiodoform seems to be one of the most energetic cicatrizants known; at least, says M. Maquenne, that is the result of a number of experiments with it in chancrous ulcers and in all kinds of severe wounds, whether accidental or surgical. At the present time it is the only antisoptic known which can replace iodoform in special applications. Different methods are employed in the preparation of diiodoform, but the most advantageous consists in the direct transformation of acetylene, by the simultaneous action of iodine and alkalies, into periodized acetylene. This is then treated with iodine in excess, which is combined by simple addition, yielding immediately diiodoform in its crude state, which can be purified by crystalization in any solvent.

Extract of Bone Marrow in the Treatment of Anæmia. -In the Lancet for March 10th Dr. J. Dixon Mann, of Manchester, having assumed that the red marrow of the bone was probably the chief agent in promoting the development of red corpuscles, says that he was led to suppose that an extract of this substance, introduced into the system in cases of anæmia, might act as a stimulant to the formative process and increase the rate of production of the red corpuscles. He remarks that in adult animals, such as the ox, the red marrow is limited to the large bones of the trunk, the thick bones of the skull, and the heads of the long bones, while in young animals, such as the calf, it is more abundant and may be found in the shafts of the long bones as well as in the other bones named. As the tissue forming power is more active in young animals than in old ones, the bones of the former are preferable, he thinks, as a source of marrow extract. To prepare the extract, the heads of the long bones, obtained from animals freshly killed, together with other portions of bone which contain red marrow, are broken into small pieces and digested in glycerin with frequent agitation. When the extraction is complete, for which several days are required, the extract is filtered and is then ready for use. It is of a red or reddish-brown color and has no unpleasant taste or odor. It may be given in teaspoonful doses once or twice a day, either by itself or spread between thin slices of bread, The first case in which Dr. Mann tried the extract was that of a little boy who was a subject of hæmophilia. He had been in a hospital repeatedly for attacks of hæmorrhage. On each occasion the bleeding had ceased, but the boy had never lost the pallor of pronounced anæmia, although he had been treated with iron, arsenic, cod-liver oil, and all kinds of appropriate nourishment. On the last occasion of his having been admitted the red corpuscles had been counted after the hæmorrhage had subsided, and been found to be 3,800,000 to the cubic millimetre. Then, on the 13th of September, 1893, the patient was put upon the use of marrow extract without any other treatment, and after an interval of three weeks the corpuscles were counted again; they then numbered 4,190,000, and a month later they had reached 4,400,000. Coincidently with this increase, says Dr. Mann, there was a marvelous improvement in the child's appearance. His face acquired a healthy color that had never been observed previously during his visits to the hospital. In the second case, that of a girl, twenty years old, with long-standing anæmia, the corpuscles numbered 3,700,000 to the cubic millimetre. After she had taken the marrow extract for three weeks they had increased to 4,000,000, and then she left the hospital. In another anæmic girl the increase in nine weeks was from 1,350,000 to 3,680,000. A man was admitted for profuse hæmatemesis, and after the bleeding ceased the red corpuscles were found to be reduced to 1,070,000 to the cubic millimetre. He was put on the use of marrow extract without any other treatment, and when the corpuscles were next counted, on the fifteenth day, they numbered 3,050,000,

Women Doctors in Switzerland, -Le Progrès médical for February 24th refers to an article published in La Revue scientifique for January 27th, on the subject of women doctors in Geneva, based on statistics furnished by Professor Laskowski, of that city, in regard to the number of women students, and followed by remarks which it seemed impossible to attribute to M. Laskowski. Le Progrès médical, while quoting the figures given by M. Laskowski, is convinced that they prove absolutely nothing. M. Laskowski, it says, had lost sight of the women medical students in Geneva who had not finished their studies there, but who probably had submitted their theses to another faculty, and La Revue scientifique has done all that is possible to efface the wrong impression produced by the article in question. M. Laskowski absolutely denies all participation in it apart from the figures referred to, and, in response to an explanation demanded of him, says that he wrote a very eulogistic article, which was published in a Polish journal (Tygodnik med. i pawiesci.), on the women medical students of Geneva, who, it says, are distinguished for their high moral tone and their diligent and persevering work. If the figures given in the statistics are small, says M. Laskowski, it is because a large number of the women medical students of Geneva have given up their studies and returned to their homes on account of sickness, privations, insufficient means of existence, or marriage. It is probable, he continues, that this article, which has been misunderstood, badly translated, and embellished with unfriendly comments, has served as a foundation for those published in La Revue scientifique and in other journals.

If M. Laskowski does not advocate strongly the study of medicine by women, he would like to see a larger number of women doctors go to Russia, where not only could they make an honorable living by their profession, but exercise a great moral influence over the ignorant and superstitious population. The editors of Le Progrès médical have published this part of M. Laskowski's letter solely to defend their colleagues from any injurious suspicions that might rest upon them. With regard to the figures given in Professor Laskowski's statement, they say, the author himself has in part explained them, and La Revue scientifique has given a still better explanation.

The Treatment of Influenza.—Dr. Juchel-Rénoy closed a recent clinical lecture at the Cochin Hospital, Paris, published in the Journal des praticiens for March 7th, by dividing cases of influenza, as regards treatment, into the grave, the pseudograve, and the benign. For the first class he recommended bathing, refrigeration, and the use of alcohol. In the second, he advised small quantities of alcohol, plentiful drinks, and revulsion by means of mustard plasters and dry cupping. For the third class, if there was pain, he said it was allowable to use antipyrine and salipyrine, but he impressed it upon his hearers that these drugs should not be used in the treatment of influenza unless the kidneys were performing their function well. He added that antipyrine was dangerous in all cases of profound and long-continuing infection. As for quinine, he said, it was of no use whatever. This he had proved over and over again.

Pyoctanine as a Remedy for Ptyalism.—In the March number of the Annales des maladies de Voreille, du largux, du nez et du pharynx there is a short abstract of an article by Heimann, published in the Therapeutische Monatshefte for February, in which the author relates a case of idiopathic ptyalism that had withstood various kinds of treatment, but was finally overcome by painting the whole of the interior of the mouth twice a day with a 1-to-1,000 solution of pyoctanine. The treatment lasted three weeks and the cure was permanent.

Rectures and Addresses.

# LECTURES ON THE DIAGNOSIS OF ABDOMINAL TUMORS.

BY WILLIAM OSLER, M. D.,
PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY.

LECTURE III.—TUMORS OF THE LIVER.

ECTURE III. - TUMORS OF THE LIVER.

(Concluded from page 389.)

HI. Syphilis of the Liver .- Of four cases diagnosticated during life as syphilis of the liver, two presented definite tumors. Diffuse syphilitic hepatitis does not produce a tumor, but gummata, either in the inherited or acquired disease, may form tumors in two stages: first, when fresh and developing, constituting nodular masses of large size, which may persist for months; and, second, gummata which have undergone cicatricial contraction and healing may so fissure and divide the liver by bands of connective tissue that an extremely nodular, irregular mass may occupy the right hypochondrium. Of the four patients this year, two died, but in neither of them were tumors felt. I show you here a photograph of the liver of one of them (Fig. 26), which will give you an idea of the extraordinary subdivision of the organ, an extreme grade of which forms the so-called "botryoid" liver, in which globular masses of normal tissue are held together by fibrous bands. The other case also, which came to autopsy, had an extremely irregular liver, and was of exceptional interest, inasmuch as the recurring

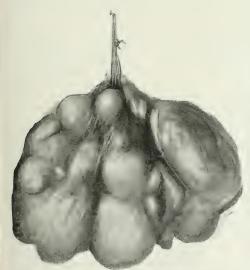

Fig. 26. -Showing the extreme irregularity of a syphilitic liver.

ascites, for which she had been tapped repeatedly, disappeared entirely under iodide of potassium, as did also nodes on her shins. In the following cases definite tumor masses were present and the correctness of the diagnosis in

both instances was in a measure borne out by the therapeutic test. In anomalous tumors of the liver it is well to bear in mind that gummata may form flat or nodular masses in the epigastric region\* which may persist for a long time, and which may, under treatment, disappear as satisfactorily as gummata of the long bones or of the testes. One of the first private patients who applied at the hospital was a young man aged about twenty-eight years, who presented just below the ensiform a flat tumor mass evidently attached to the liver, the nature of which had been very much discussed. He was sent to me for an opinion as to the advisability of a laparotomy. A positive history of syphilis was obtained and he was urged to have a thorough course of treatment. I did not see him again for nearly a year, when, to my astonishment, the tumor had practically disappeared.

Case XXX. Prominent Tumor Mass in the Epigastrium; Disappearance in Four Months under the Use of Iodide of Potassium.—John C., aged thirteen years, seen November 11th with Dr. Thayer. He had been in hospital during my absence in the summer with a tumor connected with the liver. The notes made at the time are as follows: Admitted July 13, 1892, complaining of pain in the right hypochondrium.

The father is living and is paralyzed; mother is living and well; two sisters and one brother died young; has three brothers and four sisters living.

As a child he was well, with the exception of enlarged glands, which, at about his fourth year, appeared on the right side of the neck and discharged for nearly three years.

His present illness began about three months ago with pain in the right side, which has continued, and two weeks ago became much worse; the abdomen became swollen, particularly in the upper zone and to the right side. The feet have never been swollen nor has he had any swelling of the face. Since his illness began there has been progressive loss of weight, and he frequently sweats profusely at night.

Present Condition.—Poorly nourished and not very well developed lad. Lips and mucous membranes of a good color.

\*  $\Lambda$  case illustrating an error in diagnosis is that of hospital number 5234, Joshua M., aged fifty-four, admitted May 16, 1892, with swelling of the abdomen and an illness of nearly a year's duration. The patient was a large, powerfully built man; had always enjoyed good health, and denied venereal disease. For nearly a year he had had trouble in the abdomen, and had twice been slightly jaundiced. The legs had been swollen, and he had had shortness of breath. The examination showed an enormously enlarged liver. The whole of the upper part of the abdomen was filled with a hard, irregular, nodular mass, corresponding to the greatly enlarged liver. The lower border was felt midway between the umbilicus and the pubes. There were prominent bosses on the surface of the liver, and from its great size and irregularity there seemed to be no question as to the correctness of the diagnosis of secondary cancer of the organ. No primary disease could be determined, and there was decided hyperacidity of the gastric juice. The patient remained in the hospital for a month and gained slightly in weight, but the liver developed still further, and the irregularity on the surface was more marked. An aspirator needle was thrust in, but nothing but blood obtained Naturally enough the diagnosis was entered as cancer of the liver. Dr. E. T. King, of Washington, under date of February 10, 1894, writes that he has Joshua M. under his care at present. He has a well-marked syphilitic skin eruption, and the liver, still enlarged, extends nearly to the pelvis. The time element in this case, I should think, definitely excludes cancer, while the syphilitic rash on the skin is suggestive in the highest degree that the whole trouble is specific.

Skin clear, not jaundiced. Scars on the neck just below the right ear and one on the episternal notch. The cervical glands are not enlarged; the inguinal glands are only just palpable. The epitrochlear glands are enlarged; there are no nodes, though about the middle of the right tibia there is a slight roughening. There are rhagades at the angles of the mouth; the corneæ are clear; the upper central incisors are well formed. Examination of the blood is negative.

The thorax is somewhat expanded in the lower part, particularly on the right side. Examination of the lungs and of the heart is negative.

The abdomen is prominent in epigastric and right hypochondriac regions. The hepatic flatness begins in the sixth interspace in the nipple line and extends two fingers' breadth below the costal margin. The epigastrium is filled with a firm, hard mass, which appears to be the left lobe of the liver or a mass continuous with it. It extends in the median line within two centimetres of the umbilicus, and a slight notch can be felt. The surface is somewhat irregular and a distinct rounded nodule can be felt a little above and to the right of the navel. In the nipple line the edge of the liver is difficult to feel, as the abdominal walls are rigid. The splenic flatness begins at the seventh rib and is continuous with that of the mass in the epigastrium, The edge of the spleen is not palpable.

The urine was clear, lemon-colored; no albumin; no tube casts. He had slight fever; temperature on admission 100.5° F., and every day for a week it rose to 100° F. The patient was placed upon iodide of potassium, five-grain doses three times a day, increasing rapidly until he took a drachm three times a day. He improved in weight and gained seven pounds within a month. The mass in the epigastrium gradually disappeared.

The condition to-day, November 11th, is as follows:

The boy has grown somewhat, though he looks thin. The tongue is clean; the lips and mucous membranes are of good color. He has no cough.

He certainly has not a luetic facies, though the scars at the angle of the mouth are suggestive. The edge of the liver does not appear to be below the costal border in the nipple line; flatness begins at the sixth rib in the nipple line. Palpation in the

Fig. 27. The situation of the tumor nodules in Case XXX.

epigastric region is negative until the extremity of the angle is reached, and here, just below the tip of the ensiform cartilage, can be felt a hard, firm ridge with, in the right xiphoid angle, a little prominent projection the size of a walnut. Just to the left of the tip of the ensiform cartilage a second prominent but smaller elevation can be felt. The one to the left, when he draws a deep breath, can be seen distinctly in the descent of the liver as a slight prominence beneath the skin. The edge of the liver comes about a finger's breadth below the tip of the ensiform cartilage and fills up the entire left costo-xiphoid angle.

This case is similar in some respects to one reported from my clinic at the University Hospital by Dr. A. C. Wood,\* the history of which is so interesting that I abstract it here: "He had an eruption on the skin when six months old. Did not have snuffles. Has always been robust. For several months back his mother has noticed his abdomen becoming more and more prominent. The patient has lost flesh of late. Has had no jaundice. The boy, aged thirteen, is fairly well grown, well nourished, looks a little pale; abdomen prominent, and on the right side between the navel and the costal margin there is a distinct hemispherical swelling about two inches in diameter. The tumor descends slightly on inspiration. The superficial abdominal veins are not especially dilated. The upper teeth are not good, but are not notched. He has not a syphilitic facies.

"On palpation, the lower zone of the abdomen is soft. In the left hypochondriac region the edge of the spleen is distinctly felt, with its notch at least two fingers' breadth below the costal margin. Toward the right hypochondrium a firm, solid mass is felt, the edge of which is ill-defined below and to the right. Above, it seems to pass directly beneath the costal margin in the position of the liver. The tumor is painless. The liver dullness begins in the midsternal line at the level of the sixth costal cartilage, in the nipple line at the upper border of the fifth rib, and is directly continuous with that of the tumor and reaches to within a finger's breadth of the navel. In the axillary line there is dullness from the upper border of the eighth to the lower border of the tenth rib. The left lobe of the liver does not appear to be enlarged. The splenic dullness begins at the upper border of the eighth rib and extends two fingers' breadth below the costal border.

"Fowler's solution was prescribed, four minims three times daily, to be increased by one drop each week. This was taken at intervals until the middle of January, about five months, when it became necessary to discontinue it on account of nausea and vomiting. During this time the color of the face had improved, the tumor had enlarged, and, on deep inspiration, the margin now reached the navel, and it was rough on the surface.

"In October, 1888, the patient complained of pain in both tibiæ. The pain was thought to be periosteal, and five grains of iodide of potassium were ordered to be taken three times a day. When seen again, two months later, the tumor was more nodular, the spleen had increased in size, extending three inches below the costal margin. The general condition of the patient remained good. He was now given one grain of calomel three times daily, and instructed at the end of three weeks to intermit for a week. This was continued with similar intermissions for about six months, with gradual improvement in appetite, color, and general health."

After leaving Philadelphia the boy came under the care of Dr. A. C. Wood, who reported that he returned to the hospital in February, 1890, and the mother thought there had been a slow improvement. There was, however, on the forehead a small region of necrosis of the frontal bone about the size of a ten-cent piece, which had followed a definite node. The interesting thing is that the hemispherical swelling in the hepatic region, which was so striking in this case, had practically disappeared. I demonstrated this case on several occasions before my class in the session of 1887-'88 and of 1888-'89, and on each occasion the hemispherical swelling on the right side, between the navel and the costal margin, was unusually distinctso much so that it could readily be seen by the students from the most distant benches of the amphitheater. I confess that until October, 1888, when there were pains of the tibiæ, I did not think the case syphilitic, but regarded it as an anomalous tumor of the organ. In October, 1888, however, he was given iodide of potassium and subsequently calomel. Its syphilitic nature seems to be definitely established by the development of the gummatous tumor on the forehead, which subsequently broke down and left a patch of necrosis.

Case XXXI. Syphilis of the Liver; Convulsions; Right Hemiplegia; Irregular Tumor over the Left Lobe.—On May 3d J. M., aged forty-seven years, returned by appointment to report on his condition. I had not seen him since the 25th of September of last year. The case is one of a good deal of interest with reference to the diagnosis and treatment of syphilis of the liver. I saw him first in March, 1892.

The patient is a stout man, well built, but looks ten years older than the age he gives. He is a traveling salesman, and, in response to an inquiry as to his habits, gave the characteristic reply that "he took his luck on the road." He had syphilis in 1866, and was treated for some time. For eighteen months or more he had been complaining of dyspepsia and irregular pains in the abdomen. In December, 1890, he had vomiting, and last March, just a year ago, the pains were very severe-so much so that he had to have a hypodermic injection of morphine. He had no jaundice after this attack. He went to the country, stayed until June, and improved a great deal, but he had there another severe attack of pain in the abdomen. Through the summer he lost thirty-five pounds in weight. In the autumn he had an attack of jaundice which lasted for nearly two months and gradually disappeared. This jaundice set in with pains, which were very severe. Two months ago, while sitting in his office, he fell, lost consciousness, had a convulsive seizure, followed by left hemiplegia. Gradually the power returned. He

had another convulsive seizure, with loss of consciousness, a week ago, not followed by paralysis.

When seen, March 24th, he was well nourished, not jaundiced. The point of special note was the examination of the abdomen. The panniculus was thick; the liver was enlarged. The right lobe felt somewhat irregular, but there were no definite nodules. The gall-bladder was not palpable. In the left hypochondriac region, emerging beneath the costal border, was a flat tumor mass, which extended in the parasternal line nearly to the level of the navel. It was sensitive, firm, felt about the size of the palm of the hand, and descended with inspiration. It was superficial, no definite edge could be felt, and to the right it could be separated clearly from the edge of the liver (right lobe) in the right parasternal line. On percussion, its dullness could be separated definitely from that of the spleen.

Of course, the attacks of pain, one of which was followed by jaundice, were very suggestive of gallstones. On the other hand, the anomalous character of the tumor mass attached to the left lobe of the liver, the fact that he had had syphilis, and that he had had, without obvious cause, two convulsive seizures, made me suspect that possibly the mass on the liver was syphilite in character. He was ordered thirty grains of iodide of potassium three times a day.

On the 16th of April I saw him again, after he had had for a week or more a very severe attack of nausea and vomiting,

The mass referred to was very evident. A feature of interest was the development, about a month after beginning to take iodide of potassium, of an acute parotiditis on the right side, probably secondary to the abdominal disease, such as Stephen Paget has so well described.

I saw the patient again on September 25th. He had had no attacks, no jaundice, no pains, and had not had a convulsion for five months. He has taken the iodide at intervals. Lately he has had an ulcer on one tendo Achillis, which was very troublesome, but is now healing. He has gained in weight, has been able to attend to his work, and looks very well. The tumor mass which was so perceptible in the left hypochondriac region has almost disappeared. The edge of the left lobe of the liver can be distinctly felt.

May 3d.—He reports that he has kept well all through the winter. He has had no attacks of abdominal pain, no convulsions. He has gained in weight; looks well. The condition of the liver is practically negative. Nothing definite to be felt in the left lobe, only slight irregularity as it descends in deep inspiration.

IV. Cancer of the Liver.—With the exception of the fibromyoma of the uterus, cancer of the liver may constitute the largest tumor met with in the abdomen. In extreme cases, as in the photographs I here show you, the entire cavity is occupied by the enormously enlarged liver. The diagnosis is not difficult, particularly in the secondary cancer with great enlargement of the organ. Cases of primary cancer, and especially the peculiar form of "cancer

Fig. 28.—Cancer of the liver, showing the enormous increase in the area of duliness. The shaded areas show the situation of the visible tumor masses.

with cirrhosis," may be extremely difficult to recognize  $\Lambda$  very large proportion of all cases are secondary, and characterized by a very rapid growth, profound cachexia, and often jaundice. The new growth may be so diffusely scat-

tered throughout the organ that the enlargement is uniform and the surface is smooth; but more commonly there are large outgrowths on the surface or at the edge of the liver, which form prominent tumors of the greatest value in diagnosis. Not infrequently, indeed, they project beyond the surface of the liver far enough to be seen through the thin abdominal walls, as in this photograph from a case in the hospital last year (Fig. 28). In a patient with cancer of the liver (secondary to disease of the execum), who recently died on the surgical side, these masses were of great prominence, as this photograph shows (Fig. 29). These nodules

symptoms, and vomited almost every day; never brought up any blood, and never very large quantities. She got somewhat better, and for a couple of weeks was up and about and seemed improving, and she had no chills. During the past three weeks the chills and fever have been again present, and she has had vomiting and inability to take much food. The temperature goes up to  $102^\circ$  and 103, and the chills are sometimes severe. The bowels have been constipated; she has never had any jaundice.

Present Condition.—Patient is not cachectic-looking; face has a grayish, rather anamic aspect. Tongue is slightly furred. Examination of the thoracic organs is negative.

Fig. 29.—Showing the nodular masses of cancer of the liver,

are known in the older literature as Farre's tubercles of the liver. They vary in size from a walnut to an orange; they are usually firm and hard, the edges rounded, and the ceners cupped—a sort of umbilication caused by the fibroid and degenerative changes going on in the central portion of the mass. Frequently these characters can be determined on palpation, and are of special importance in diagnosis. In the following cases tumor masses were present:

Case XXXII. Cancer of the Liver; Chills, Fever, and Sweats.—Mrs. S., aged sixty-nine years, seen with Dr. Amanda Norris on April 30th. Family history good; husband died in 1879 of cancer of the stomach.

The patient has been a strong, healthy woman. During the past winter has not been in good health, has been losing in weight, and has had indigestion. She has kept about, and the condition was not thought to be serious until March 4th, when she had a severe chill with pain in the right side. There was no cough, no signs of any pleural or pulmonary trouble, nor had she any jaundice. The chills recurred very frequently, sometimes every day; she was in bed for three weeks. The fever rose, and she had heavy sweats. She had also marked gastric

The abdomen is somewhat full; panniculus moderately thick; the upper zone of the abdomen a little prominent. On palpation, it is everywhere soft on the left side and below. Occupying the upper umbilical and all of the epigastric regions and extending to the right in an oblique line toward the anterior superior spine there is a solid resistant mass, which descends on inspiration. It is evidently a greatly enlarged liver. In the anterior axillary line the edge descends unusually low, and here, at a short distance from the anterior superior spine, there is a prominent nodular mass as large as the top of a lemon, firm, hard, attached to the liver. It gives one the impression of a secondary nodule. A second mass, not so large, can be felt just above the border of the liver in the nipple line, and a third at the edge of the liver, a little beyond the left upper sternal line. The upper limit of the liver dullness is greatly extended, particularly in the nipple and anterior axillary lines. The stomach does not appear to be dilated. No tumor mass to be felt on deep pressure in the left hypochondriac and umbilical regions; the spleen is not enlarged.

As usual, the chills in this latitude had been taken to indicate malaria, and she had been saturated with quinine for weeks without any influence. Chills with enlarged liver mean in the

great majority of cases suppuration, either abscess or pylephlebitis. Here in a woman the onset with pains and the early chills suggest, even in the absence of jaundice, that the whole trouble may depend upon gallstones, and that the chills may be associated with suppurative cholangeitis.

Chills and fever may, however, occur in cancer of the liver, and in this case the emaciation, the enlargement of the organ and particularly the nodular masses, suggest the presence of a neoplasm. The chills and fever may be associated with the rapid growth of cancer, but in the liver the suppuration may be in some of the large bile ducts, blocked with the neoplasm. Dr. Norris wrote that subsequently jaundice developed. The fever persisted, and before her death the emaciation was extreme.

Case XXXIII. Large Nodular Tumors at the Edge and Surface of the Liver .- Mrs. S., aged about fifty years, consulted me January 24th, complaining of cough, loss of flesh, fever, and shortness of breath on exertion. There was slightly deficient expansion at the left apex, and a few râles in the suprascapular region. An examination of the sputum showed tuberele bacilli. I did not see the patient again until October 18th in consultation with Dr. Aaronsohn. She had had pleurisy on the left side, with some effusion, which had almost completely disappeared. She had become progressively weaker; had had some loss of appetite, but no marked gastric symptoms. On examination of the abdomen, however, there was felt a remarkable ridgelike tumor extending just below the level of the navel, with a very hard, everted, and irregular edge, above which was a sort of shallow groove. The abdomen was much relaxed and the intestines lay between the abdominal wall and this ridgelike mass. At first I thought it possibly might be the omentum curled up and indurated, but on more careful palpation it was evident that the indurated, irregular edge was continuous with the liver. The extreme hardness and irregularity were, of course, very suggestive of cancer, in favor of which also were the enlargement and the pain on pressure.

I saw this patient again in consultation on the 30th and 31st, and the two weeks which had elapsed had made a very striking change in the condition of the liver. It was considerably below the level of the navel. The irregularity was very much more pronounced, and definite nodular masses could be felt both at the edge and on the surface. One of these, a little to the left of the middle line, was at least six centimetres in diameter, with a rounded edge and a depressed center. The condition was still a little peculiar and unusual from the fact that the abdominal walls were extremely relaxed and the intestines lay in front of the liver, so that there was resonance as high as the costal margin. The growths in the liver were, from their local character, evidently secondary, and though the patient had profound anorexia, there was no evidence as to the seat of the primary disease. She died a few days after my last visit.

Case XXXIV.—Enlargement of the Liver; Prominent Mass in the Upper Umbilical Region; Latent Cancer of the Stomach.—Henry T., aged fifty-nine years, admitted October 4th, complaining of pain in the abdomen and back. Family history is good.

Has been a temperate man and has had no serious illnesses. Three months ago he says he was quite well. About eight weeks ago noticed that he had occasional pain in the abdomen, which for the past four weeks has been constant and of a dull aching character. He only stopped work three weeks ago; has lest, he says, thirty pounds in weight in two months. His appetite is poor; has never had any vomiting; has no nausea. Food makes no difference in the pain. Two days ago his feet began to swell.

Patient is a tall man, much emaciated. The skin has everywhere a sallow tint, and the conjunctive are slightly tinged. Tongue moist, covered with a white fur. Condition of thoracic organs is negative. Abdomen much distended in epigastric and hypochondriac regions, especially on the right side. In the upper part of the umbilical region there is a prominent mass which is to be seen readily, and which moves up and down with respiration. On palpation, it is felt to be separated by a distinct groove from the swelling in the right hypochondriac and epigastric regions. The surface is smooth, painless; no nodules are to be felt, but on the lower margin which extends to the navel it is distinctly irregular. The percussion dullness does not correspond to the edge of the mass, but is fully a hand's breadth above it. The upper limit of dullness is at the fifth rib in the nipple line, and at the seventh in the midaxillary. The splenic dullness is not increased; the edge is not palpable.

The urine was dark brownish-yellow and contained a faint trace of albumin.

There seemed no question at all that this was a liver enlarged by cancer, but at first the prominent mass in the umbilical region, which seemed separated from the upper part by a distinct groove, raised a slight doubt; but the profound cachexia, the rapid growth, and the irregular, nodular edge seemed conclusive. The primary trouble was not evident. The examination of the rectum was negative. A test breakfast, withdrawn fifty minutes after, gave fifty cubic centimetres of a dirty reddish-brown fluid consisting of undigested food, and showed a great many blood-cells. Free hydrochloric acid was not present. On the 10th he had been suffering a great deal of pain, and following three injections of a sixth of a grain of morphine at 9 A. M., 3 P. M., and 10 P. M., he became profoundly comatose, and died at 2 A. M. on the 11th.

The autopsy showed the primary carcinoma to be in the stomach, at the greater curvature, just eight centimetres from the cardiac orifice. The liver was enormously enlarged and weighed five kilogrammes and a half. The prominent tumor in the upper umbilical region felt during life corresponded to a new growth in the left lobe of the liver, which formed a projecting knob ten by ten centimetres in extent. The entire organ was occupied with small and large secondary nodules, very little liver substance remaining. The bile ducts were not affected. There were secondary nodules of cancer in the pancreas.

The following case is of great interest from the local character of the tumor masses, which in the epigastric region were so prominent, soft, and fluctuating that the condition of abscess of the liver was suspected. It illustrates, too, the importance of obtaining a thorough history.

Case XXXV. Sarcoma of the Liver; Two Prominent Tumor Masses in the Epigastric Region; Diagnosis of Abscess; Exploratory Laparotomy.—E. K., aged nineteen years, seen September 6, 1892, with Dr. McGill. Condition on visit was as follows: The most extreme grade of emaciation, particularly of the face. The skin was bathed in perspiration; pulse, 104, of fair volume and good tension; respirations quiet; no fever.

On exposing the abdomen, the upper zone is distinctly full, and two tumor masses are visible in the middle line, the smaller and less prominent just below the ensiform, and the other, a larger hemispherical mass, bulges the thin, tense skin between the ensiform cartilage and the navel. Both rose and fell with the respiratory movements. No glandular enlargements were visible.

On palpation, the superficial tumor masses were not tender,

nor were there any spots of special sensitiveness anywhere over the liver. The lower and larger mass was soft and appeared to be distinctly fluctuating. The upper tumor was not quite so soft, and fluctuation could not be obtained between the two. The apparent fluctuation was also recognized by Dr. Tiffany, who had seen the patient some days before. A distinct ridge, like the edge of the liver, could be felt two fingers' breadth above the navel and extended to the right, passing at the anterior axillary line beneath the costal margin, at which point there was a somewhat indistinct irregularity.

The liver dullness began on the midsternum opposite the sixth costal cartilage, and extended within two fingers' breadth of the navel. In the midaxillary line it was at the eighth rib and the dullness was not increased at the right infrascapular region.

The condition of the heart and lungs was negative. The digestion was good and he had been taking plenty of nourishment. Lately he had had occasional attacks of diarrhoa.

. The history of the case was not very satisfactory. He had been a fairly healthy lad, but had some indefinite illness this summer, and had gone out to Colorado with a friend. He was there on a ranch, and seemed to be fairly well until about six weeks ago, though he had apparently been losing in weight. He became much worse after a long ride, and about three weeks ago his father was summoned and immediately went to Colorado and brought him home. Since his return the chief symptoms have been progressive weakness and loss of flesh. The liver was found to be enlarged, and the tumor masses above referred to have within the past ten days become very prominent. There have been no definite chills, though he has occasional chilly feelings. The temperature has on no occasion been elevated and not infrequently been subnormal. He has had heavy sweats, particularly during sleep. No history could be obtained of any attack like dysentery, though he has had looseness of the bowels from time to time.

The first glance at the emaciated form of the patient at once suggested a new growth, but the age, the quick onset, and more particularly the examination of the superficial tumor masses and their rapid increase in size, seemed to favor the existence of abscess. Suppurating hydatid tumor could not be definitely excluded, though the rapid course was against this idea; also the profound emaciation which, though rare, is occasionally present, as in the case of an Italian who came under my observation in Montreal.\* I suggested the propriety of aspiration or of an exploratory incision, and this the next day Dr. Tiffany proceeded to do. I then learned for the first time that in May, 1891, more than eighteen months ago, the lad had had disease of one testis, which had been removed, and Dr. McGill states that on section it seemed to be in a sloughing condition. He had, however, bruised himself on his bicycle. This fact was of very special importance in the history of the case, as it seemed most likely that the liver condition was associated with the disease of the testis, and from the length of time which had elapsed since the removal of the organ it rather favored the idea that the condition was neoplasm. I must say, however, that the physical examination of the two tumor masses in the epigastrium led us all to expect fluid, and I should unhesitatingly have put in an aspirating needle with the expectation of withdrawing either pus or a clear fluid.

Dr. Tiffany made an incision four inches in length over the lower tumor and exposed a large hemispherical swelling in the left lobe of the liver. There were no adhesions; the superficial substance had a natural reddish-brown color, and puncture with the hypodermic needle withdrew nothing but blood. Dr. Tiffany inserted his fingers and examined the upper mass,

which was a second soft enlargement, and on the under surface of the liver there were several others, leaving no question that there was a multiple new growth in the organ. The patient was extremely weak after the operation, but rallied for a few days.

In this case, as in one or two others which I can call to mind, I have been led astray by the deceptive, semi-fluctuating character of liver tumors.

Primary new growths in the liver in young men are, of course, extremely rare, and, taking all the circumstances of the case into account, it is more rational to suppose that the lad had a new growth in the testis, which was bruised by the bicycle, and it was this in an inflamed condition which Tr. McGill removed in May, 1891.

The presence of tumor masses on the liver is, then, one of the most distinctive features of cancer of the organ, more particularly of the secondary form, which constitutes so large a proportion of all cases. The primary lesion is to be looked for in the stomach, intestines, urogenital organs, or the breast. The new growths are scattered diffusely with large nodular masses on the surface or at the edge. The rounded margin and cup-shaped depression are pathognomonic of these secondary cancerous nodules. The irregular syphilitic liver could alone be confounded with it, but in this condition there is rarely progressive enlargement of the organ, and the general features of the case are those of cirrhosis of the liver.

Tumor masses, as a rule, are absent in the primary cancer of the organ and in the form known as cancer with birrhosis, in both of which conditions the organ may be of normal size, or even somewhat reduced. Lastly, large, rapidly growing encephaloid or sarcomatous growths may, as in Case XXXV, produce prominent tumors evident beneath the skin in the epigastric region, and which may apparently fluctuate, due either to the very soft nature of the neoplasm, or in some instances to hæmorrhage.

# A CLINICAL LECTURE ON EXOPHTHALMIC GOÎTRE (GRAVES'S OR BASEDOW'S DISEASE).

BY JAMES K. CROOK, M. A., M. D.,
INSTRUCTOR IN CLINICAL MEDICINE
AT THE NEW YORK POST GRADUATE MEDICAL SCHOOL
PHYSICIAN TO THE OUTDOOR DEPARTMENT OF BELLEVUE HOSPITAL.

Gentlemen: We have this morning a patient whose case presents the well-marked features of a somewhat remarkable and not very common form of disease. The patient is M. R., unmarried, aged twenty-two years. She has no employment, but lives at home with her parents. She comes to us to-day to be treated for a cardiac affection which, we are informed, has troubled her for five or six years past. Palpitation and painful action of the heart are of every-day occurrence, and are increased by even moderate exercise or exertion. The patient also suffers from muscular weakness, a capricious appetite, and general debility. The trouble is not so severe as to keep her in bed, but she never feels as well as other girls. In reply to a question she states that she sweats considerably, but much more on one

<sup>\*</sup> American Journal of the Medical Sciences, October, 1882.

side of the face than on the other. An inspection of the patient's face reveals several facts of importance. She has a very anæmic aspect, the face and prolabia being bloodless: at the same time the skin is very dark-many shades darker than that of her mother who sits by her side. We are informed, however, that her father was a very darkskinned man, which fact may account for our patient's peculiar complexion. Another feature of more interest is the singular appearance of the eyes. An unnaturally large area of the tunica albuginea is exposed, giving the patient a wild, staring appearance. A close inspection shows that the balls of the eyes protrude abnormally from the orbits, so much so as to cause some stretching of the lids in order to close them. You will also observe a defective coordination between the movements of the eyeballs and those of the lids. When the patient looks down or up, the lids do not closely follow the movements of the globes, but are raised or depressed one at a time and in a faltering or hesitating manner. The constant stretching of the lids is no doubt responsible for the well-defined ædematous line which you will notice along their margins. Gentle pressure over the closed eye is sufficient to restore the globe to its natural position, but removal of the pressure is at once followed by renewed protrusion. The sight is not affected, but the eyes tire very quickly. The patient states that she went to a dispensary to be treated for weak eyes about four years ago. The doctor gave her some drops to put into them, and soon after her friends began to notice their undue prominence. The oculist must therefore, in the opinion of the patient and her friends, shoulder the responsibility for this condition, which is about as reasonable as many other accusations laid at the doctor's door. A casual inspection of the patient's neck would give you the idea of simple local fatness, but a closer examination will show you that this appearance is confined to the region of the thyreoid gland. We find that both lobes of this body are very materially and uniformly enlarged. The body is quite soft and pulsation may be noticed in it. This enlargement, we are informed, commenced some time after the heart symptoms appeared. Its growth was very slow and was hardly noticed for several years. The patient does not think it is enlarging at all lately. We find the pulse beating at the rate of 98 per minute. It is rather weak and vibratile, and a brisk walk around the amphitheater raises it to 130 a minute. There are no signs of organic heart disease, but a remittent, humming sound is heard over the right internal jugular vein, just above the sterno-clavicular articu-

Among these subjective and objective symptomatic features there are three which point to a rational diagnosis of the case—viz., the exophthalmia or protrusion of the eyes, the thyreoid enlargement, and the quick heart. This clinical triad embraces the chief pathognomonic phenomena of a peculiar affection which has received the name of exophthalmic goitre, after the two more prominent features. It is otherwise known as Graves's disease among English, French, and American writers, after Dr. Graves, who wrote the first succinct account of the disease as an individual affection in 1835; and as Basedow's disease among the Gertion in 1835; and as Basedow's disease among the Gertina disease are successed to the disease are successed to the disease are also the Gertina disease.

mans, after Professor Basedow, whose classical description appeared in 1840. These features are all very well marked in this young girl, and we need feel no doubt as to the identity of the affection. As corroborative symptoms we have the appearances of anæmia and also of hemidrosis (unilateral sweating). The exact pathology of this disease is still open to doubt, but it is believed to involve the vasomotor and sympathetic nervous systems. In a few instances where autopsical examinations have been possible the cervical sympathetic nerves have shown morbid appearances, but in the majority of cases they were found to be unaffected. The affection does not seem to involve structural lesions, and may therefore be properly classed as a neurosis. The protuberance of the eyeballs may be partially due to an increase in the post orbital adipose and areolar tissue, but it is probably to a much greater extent caused by an enlargement of the blood-vessels in this locality. Vascular engorgement is also responsible for the thyreoid enlargement, supplemented later along by hypertrophy of the fibroid structure of the gland. No satisfactory reason has been assigned for the increased frequency of the heart's action. The anæmia, emaciation, and muscular weakness which are usually present may in some cases be responsible for this symptom, but cases occur in which these concomitants are absent. The disease occurs with vastly greater frequency in the female sex, probably in the proportion of 3 or 4 to 1, and is almost invariably found between the twentieth and fortieth years of life. Depressing emotions, fright, worry, and nerve shock have been supposed to have some influence in the causation, and heredity has also seemed to play a part in certain cases. Beyond this, speculations as to the ætiology are valueless, as we have no adequate data in the present state of our knowledge for determining the exact causation. With reference to the prognosis it may be said that the disease possesses no intrinsic tendency to destroy life, but it augments the danger of intercurrent affections. This young girl could hardly withstand an attack

of pneumonia or typhoid fever, for example, as well as if she were free from Graves's disease.

The affection is essentially chronic and extends over a long period of time. This patient, according to her history, has already suffered six years from it. A few patients are eventually worn out and die from exhaustion, while others succumb to dilatation and enlargement of the heart, due to the constant acceleration.

Exophthalmic goitre. Photograph by Mr. J. M. Dixon.

tion. Still others, probably twenty-five or thirty per cent., overcome the debilitating effects of the disease and eventually recover. In a small proportion of the recoveries the exophthalmia may remain permanent, owing to paresis of the recti muscles from constant overstretching. Some enlargement of the thyreoid also occasionally persists, but in a majority of those who get well all traces of the disease disappear. Our

present patient has certain indications in her favor-viz., a fair appetite and digestion and only a moderate degree of cachexia; nor is the heart's action excessively accelerated. In the therapeutics of exophthalmic goître we have no pathological entity to combat, hence there are no specifics for the affection. The treatment, therefore, resolves itself to a great extent into the management of the indications as they appear. In the case of this young girl the cardiac palpitation and the anæmia require immediate attention. The patient should be placed under the best attainable hygienic conditions. She should receive a bland and unstimulating but nutritious diet. Such articles as milk, meat juice, and soups should enter largely into the daily regimen, although solid food may be partaken of with proper avoidance of the danger of upsetting the weakened digestive power. Everything should be done to avoid depressing emotions and to preserve a cheerful frame of mind. Alcohol, tea, and coffee should be used sparingly if at all. The patient need not be confined to bed, but a considerable part of each day should be passed in an easy chair, or in a position requiring little muscular exertion, although a short time may be spent outdoors daily when the weather is agreeable. For the persistently painful heart's action in this case I would recommend a prescription composed as follows: R Tinct. aconit. rad., nitroglycerin (cent. sol.), āā Mj; ext. cacti grandiflor. (P. D. & Co.), Mx; aquæ dest., q. s. ad f 3 j. One dose to be taken three times daily-on rising, at noon, and at bedtime. For the anæmia I would advise a five-grain Blaud pill combined with a grain of quinine to be taken after each meal. One drachm of pure cod-liver oil may be taken at the same time if well borne. A soft, nicely fitting bandage applied over the eyes at bedtime will promote the patient's comfort during the night, and relieve the tension of the eyelids. It is said that such a bandage applied snugly to the neck will facilitate the diminution of the thyreoid enlargement, but I have had no personal experience in this direction. The use of the galvanic current has the sanction of a number of eminent authorities in the treatment of this disease, but its use must be persisted in for a long time in order to be of benefit.\* A daily bath would probably be of advantage in this case, given after the method of Jaccoud. The water should be quite warm at first and gradually lowered with each succeeding bath until it is as cold as can be borne without shock. The baths should not be of more than twenty-five or thirty seconds' duration.

The Shadow Test.—A course of lectures, demonstrations, and clinical work on skiascopy, or the shadow test, will be given at the Philadelphia Polyclinic during the week beginning April 9th. This method of determining the refraction of the eye has for years been practiced as a part of the regular routine examination in that institution, and is there thought to be of greater practical value than the methods by the use of the ophthalmoscope or the ophthalmometer.

## THE TREATMENT OF DEVIATIONS OF THE NASAL SÆPTUM.\*

By JOHN O. ROE, M. D.,

The predisposing and exciting cause of many chronic diseases of the air-passages is nasal obstruction, which results perhaps as often from deviations and excrescences of the nasal sæptum as from any other conditions. The frequency with which deviations occur is very great; in fact, they are so often found that Stoker† says he doubts if such a thing as a perfectly straight sæptum exists. The following statistics give some idea of the frequency of deviations of the sæptum:

Zuckerkandl‡ found deviations in 37.8 per cent.—140 in 370 cases observed by him; Delavan,\* in fifty per cent.; M. Mackenzie, || in 76.9 per cent.—1,657 in 2,152 cases; Jarvis, ^ in eighty-one per cent.—81 in 100 cases; Sedziak, ◊ in 83.5 per cent.—167 in 200 cases; Simanovsky, ‡ in ninety-five per cent.—925 in 974 cases; P. Heymann, ‡ in 96.4 per cent.—241 in 250 cases; Von Klein, ‡ in ninety-eight per cent.

Nearly all statistics collected upon this subject are defective since they fail to specify the location of the deflection. It is a fact, however, that two thirds of all cases of deviation are confined to the cartilaginous and to the anterior portion of the osseous part of the sæptum. This is illustrated in the statistics just cited. Zuckerkandl's observations were made from dry skulls in which he found but 37.8 per cent. of deviations, indicating that in these cases the deviation was confined to the osseous portion, whereas in observations made entirely upon the living subject, in which the cartilaginous portion is present, the percentages reach from fifty to ninety-eight.

\*\*Classification.—Various attempts at classification have been made in regard to the form of the deviations, and nearly every writer on this subject has a classification of his own. Thus Loewenberg \*\* divides them, according to their situation and direction, into superior, inferior, horizontal, and vertical deviations; Jarvis, †† into osseous, cartilaginous, and osseo-cartilaginous; Sedziak, †† into simple deviations to the right or left, and deviations with partial

<sup>\*</sup> An elaborate paper on the electrical treatment of Graves's disease will be found in the Lancet, July 4 and 11, 1891. Mr. Cardew, the author, uses a weak continuous galvanic current (tvo to three milliampères), and has it applied for six minutes three times a day.

thickening; Stoker \* considers the subject under the follow-

Angular, curved, sigmoid, dislocations (so called), spurs, adhesions, exostoses; Rosenthal + has divided deviations of the sæptum into six different classes:

- 1. Simple deflection without thickenings.
- 2. Deviations with thickenings or spurs.
- 3. Sigmoid deviations in vertical or anterio-posterior
  - 4. Sigmoid deviations of both kinds with spurs.
  - 5. Cristæ, without deflection of the nasal sæptum.
  - 6. Zigzag deviations.

The division of deviations into osseous, cartilaginous, and osseo-cartilaginous, as suggested by Jarvis, is by far the most natural method, and all attempts at further classification are necessarily futile, since the sæptum varies as much in its size, shape, and position as does the external contour of the nose or the face, and in no two cases are there found the same amount and kind of deviation. Sedziak's second division, consisting of deviations with partial thickenings, in the shape of spurs (spinæ, cristæ), is misleading. This is a condition of apparent deviation, but not a real one, for it is often the case that one nostril will be occluded by an osseous outgrowth or spur, whereas the sæptum on the opposite side may be straight. This condition is not treated as a deviation of the sæptum, and can not therefore be classed as such.

Treatment.—Before detailing the methods that I have found most efficient in the correction of deflections and deformities of the nasal sæptum, it may not prove uninteresting to review briefly and systematically the methods that have been from time to time proposed by others and found by them to be of the most service.

The treatment of deviations of the sæptum may be divided into palliative and radical.

Palliative treatment consists in the adoption of such measures as may remove the exciting cause-such as the removal of turbinated hypertrophy, or of an osseous growth of the turbinated body, or the removal of enlarged tonsils, adenoid growths, and such other conditions as may obstruct the nostril and interfere with proper development of the

Radical treatment consists in the employment of measures by which the deviation is forcibly and more or less speedily corrected, and may be divided into (1) non-surgical and (2) surgical.

(1) Non-surgical Treatment.—Non-surgical methods are those by which the sæptum is forced to the proper position without the employment of cutting or lacerating instruments. They are efficacious mainly where the deflection is confined to the anterior or cartilaginous portion of the sæptum, and consist in the employment of pressure upon the convex side sufficient to force the sæptum back into the median line. This may be accomplished in two ways: by slowly forcing the sæptum back into place; or by forcing it into place at once and holding it there by means of a retentive apparatus. The former method was the one first proposed for the correction of deviation of the sæptum. This was brought forward by Quelmalz \* a century and a half ago, and it was he who was the first to call attention to the importance of correcting deviated sæpta. His plan was to force it back into place by daily digital pressure, until the sæptum retained its normal position. Since his time this method has also been advocated by many others. Michel, † in 1876, recommended pressure in a similar manner upon the convex side of the deviated sæptum from fifty to a hundred times a day. In 1888 Boyer t proposed the application of a bandage to the external portion of the nose sufficiently tight to modify the deformity. Massei, # Boucher, | and Masucci A have proposed the employment of compressed air from the apparatus of Waldenburg for about five minutes several times a day. Dionizio \( \rightarrow \text{suggests} \text{ the introduction during the night of a gauze or cotton tampon into the nose, to exert a more or less continuous pressure after the employment of compressed air. The attempt to force the sæptum into the median line by the use of prepared sponges, metallic sounds, and the like, has been abandoned on account of the irritation they excite and the comparatively small amount of good accomplished.

Rapid dilatation of the occluded nostril and restoration of the sæptum may be accomplished by the use of dilating instruments, such as the nasal dilator figured and described by Woakes t in 1883. The instrument proposed by Woakes is, however, of very slight power in comparison with the dilator proposed by Hewetson three or four years ago. Hewetson's instrument very much resembles a large steel glove stretcher, and was primarily devised for the treatment of nasal stenosis. This method has also been employed with success by Hill, & Scanes-Spicer, \*\* Lennox Browne, ++ and Orwin, ††

- (2) Surgical Treatment.—The correction of deviation and deformities of the sæptum by surgical means may be accomplished by a variety of methods. They may be enumerated as follows:
  - By the use of forceps having flat parallel blades.
- 2. By removal of the prominent portion of the deflection with (a) knife, (b) chisel, (c) saw, (d) scissors, (e) files, burrs, drills, and gouges, (f) needle and snare, or (g)
- 3. By the destruction of the prominent portion with caustics, electrolysis, or galvanic cautery.
  - 4. By incising the sæptum with knife or cutting forceps.

5. By the employment of pins.

6. By fracturing the sæptum by means of comminuting forceps.

1. Forceps with Flat Blades, - The method of correcting the deformity by means of forceps was first proposed by Adams, \* of London. His well-known forceps is constructed with strong, flat blades, a blade being inserted in each nostril and sufficient pressure exerted to force the sæptum into place. The sæptum is then retained in its proper position by ivory plugs or steel plates, held by screws, until the cure is complete. Too great pressure must be carefully avoided, while frequent cleansing is also needed. After a time the ivory plugs may be replaced by plugs made of wadding or oakum. Jurasz † modified this method by employing forceps with detachable handles, so that the blades of the forceps could be left in situ after making the correction, and held firmly in place by means of screws. This method of procedure has been still further modified by Delstanche, t who has the blades of the forceps covered with rubber. Hope, # of New York, has devised a forceps to be used in connection with the Adams forceps in the operation for the refracture of the sæptum. By the action of one blade carrying a steel pin, which is received into a corresponding circular opening in the opposite blade, the sæptum is pierced with a line of punctures drawn at a sufficient interdistance to map out a direction of fracture in exact conformity with the intention of the operator; and, in completing the separation of the bony continuity with the Adams forceps, any extreme force ordinarily necessary is obviated. Garrigou-Desarènes | has described an instrument devised by him for correction of deviated sæpta. The forceps is composed of two blades, with corresponding convexity and concavity, which are placed in each nostril; these two blades are tightened by a screw before the fracturing of the cartilage.

2. Knife, Chisel, Saw, etc.—Excision of the prominent portion of the deflected cartilage with a knife, so as to render the occluded nostril free, was first practiced by Dieffenbach ^ in 1845. This method is still employed by Geuzmer ◊ and many others. Heylen ↓ modified this method by first dissecting the mucous membrane carefully from the surface of the deformity, and then removing the prominent portion of the cartilage with scissors. Demarquay ↓ describes a still more complicated operation by which he opens the nasal cavity by an incision along the ridge of the nose, in the median line, in order to gain free access to the parts. The mucous membrane is then dissected from the prominences, which are removed with a knife. The membrane is then united over the part by sutures, the external wound being closed in the same manner. In anterior cartilaginous de-

viations Ingals,\* of Chicago, has modified the methods of Dieffenbach and Heylen as follows: He makes first an oblique incision through the membrane of the convex portion of the prominence. The membrane is then detached a certain distance on each side of the cut from the underlying cartilage, thus exposing the latter. A V-shaped piece is then excised from the deflected cartilage, and the parts are brought together by sutures, the cartilage being pressed into line and supported by means of tampons. Similar means for the correction of the deformity have been adopted by Petersen,† Moldenhauer,‡ Krieg,\* and also by Post of New York, as quoted by Robinson.

Hartmann,<sup>△</sup> in 1884, was the first to make use of the chisel for the excision of the prominent portion of the sæptum. Heymann ◊ likewise employs an ordinary carpenter's chisel in removing the projecting portion, a method that has been adopted by Seiler. ↓ The chisels employed by Seiler are, however, very delicately constructed, being operated either by the hand or a small mallet.

The saw is especially adapted for the removal of osseous or cartilaginous spurs, usually found along the convex angle of the deflection, or occurring as inflammatory deposits along the line of junction of the different portions of the sæptum, or of the sæptum with the superior maxilla. Such deposits are often found when the sæptum is scarcely or not at all bent. The most ardent advocate of the saw is Bosworth. After giving Woakes and Seiler credit for previous use of the instrument in correcting nasal deformities, Bosworth thus describes the form of saw employed by him: "The blade is as thin as possible, consistent with strength, an eighth of an inch wide, five inches long, with a cutting edge of three inches, with thirty teeth to the inch, each tooth an exact equilateral triangle, with no cross-cut and no set to the teeth, the handle being three inches long, of sufficient size to be grasped by the hand, and attached to the blade at an angle of forty-five degrees, in order that the hand should in no way obstruct the view while operating. These saws are constructed in two forms, one with the cutting edge upward and the other with the cutting edge downward." Especially adapted for the removal of spurs and ridges from the sæptum are the small bow saws that I devised for intranasal work about four years ago and presented to this association in 1889.1 These saws, by reason of the blade being held firmly by a rigid bow, are superior to the ordinary nasal saw, in that the blade is not readily deflected from the straight line.

p. 143.

One of the principal objections to Bosworth's pattern is that the slender blade is so flexible that, in holding the blade up against the sæptum on starting the saw, it is quite apt to be bent out of the straight line, and therefore in sawing describe a curve.

Scissors of different patterns have been devised by different operators for the removal of excrescences from the sæptum. The writer has for about twelve years used a pair of toothed or grapevine scissors, devised by himself, with the blades set at an obtuse angle to the handles, so that the view of the blades may not be obstructed by the hand. Especially constructed scissors have also been devised by Seiler,\* Jarvis, † Sherwell, † and Fraenkel. #

Sandmann || makes use of files to remove osseous growths from the sæptum.

Burrs, similar to dental burrs, for the removal of excrescences from the sæptum, were, I believe, first employed by Goodwillie, and afterward adopted by Seiler. ◊ These are operated by a dental engine or an electro-motor. Goodwillie has since devised a shield for the burr, to prevent injury to the soft parts. The nasal plane devised by Jarvis t is simply a burr projecting slightly through a flat shield. By passing it over a rough surface, the inequalities are removed or planed off. The drills devised by Curtis 1 are of special service in the removal of bony growths and exostoses. The only objection to their use that can be raised is the rough and irregular surface they may leave. In addition to the above-named surgeons, the trephine has as its advocates Bronner, 1 J. Wright, \*\* Astier, † and Lennox Browne. ## In most instances the use of drills is regarded as but preparatory for the easy admission of the nasal saw.

Wright \*\* has proposed the plan of employing a nasal trepan for the purpose of making a hole from the anterior to the posterior end of the deviation, in such a manner that it goes as close to the mucous membrane on the opposite side as possible without perforating it. Into the resultant tunnel a saw is inserted and the exostosis is removed by sawing upward and downward from the opening made by the drill. This plan has also been adopted by Lennox Browne.

Gouges of various devices have been employed for the removal of sæptal projections and irregularities. To trim off portions of redundant cartilage, Weir <sup>AA</sup> employs a gouge forceps, mounted like a dressing forceps, and Jarvis\* has for the same purpose devised his fenestrated cartilage forceps. For bony growths and ridges Jarvis uses his rongeur forceps. In order to avoid the destruction of the mucous membrane, Greville MacDonald † incises the muco perichondrium over the center of the bony ridge or growth to be removed with a small, especially constructed knife, and raises the periosteum with his spud or "raspatory." He then removes the bone with his flat, curved, or triangular gouges and replaces the flaps.

The method of removing the salient portion of the sæptum by means of needle and snare, proposed by Jarvis in 1882, may be briefly described as follows: The base of the cartilaginous projection is pierced with a transfixion needle until the point reappears. The wire loop of the écraseur is now passed over the point of the needle projecting into the nostril, and tightened around the transfixed tissue by forcing up the outer cannula with a movement of the finger against a milled nut. A few turns of the milled nut cause the wire to sever the engaged portion.

For the purpose of removing an angular portion of a deflection or a unilateral obstruction to respiration, punches of various forms have been devised, such as those by Blandin, Rupprecht, Roser, and Goodwillie. In all respects they resemble that first proposed by Blandin, which consists essentially of a modification of an ordinary shoe punch. Another variety of punch, or stellate blades, has been devised for the purpose of making incisions in the cartilage sufficient to overcome the resiliency. This idea is simply a modification of the plan adopted by Chassaignac, who dissected up the mucous membrane and then made a number of incisions through the deflected portion by means of a knife, which rendered the cartilage pliable, so that it could be maintained in a vertical position until it became solidified. The first device adopted for the accomplishment of this object by means of a punch was that used by Bolton. † His instrument was similar to a buttonhole scissors, by which he was enabled to make incisions in different directions by changing the direction of the handles. Steele 1 further modified this form of instrument by adopting a stellate punch, so that the operation is completed at one sitting.

3. Caustics, Electrolysis, and Galvanic Cautery.—Bresgen, ‡ in 1887, proposed for the correction of cartilaginous deviations the use of chromic acid, either in crystals or in concentrated solutions. Miot,\*\* in 1888, was the first to make use of electrolysis to remedy thickenings or

deviations of the septum. Garel,\* Moure,† Botev,† Tilly,\* and Rosenthal | have confirmed the good results obtained by Miot. Needles of steel or platinum are ordinarily used. Originally Miot connected the needles used with only the negative pole, but Moure and Bergonie A make use of both poles. This latter method has the advantage of being more rapid and less painful than the former. The action of electrolysis is due to the cauterization of the tissues by decomposition of the liquids, since, in proportion to the intensity of the current, acids are formed at the positive pole and alkalies at the negative. The use of the galvanic cautery, so warmly recommended by Voltolini, was first proposed by him in 1888. In deviations of the cartilaginous sæptum, by means of the galvanic cautery he removes enough of the prominent portion to make it possible to force the sæptum into place, for which purpose acids and electrolysis are likewise employed.

- 4. Incision of the Suptum.—In the correction of deflections confined to the cartilaginous portion of the suptum Asch the employs, for incising the most prominent portion of the deflection, a pair of strong cartilage scissors similar to a pair of buttonhole scissors, or much like those employed by Bolton. He then forces the suptum into place by Adams's forceps and holds it there until it has become firm by means of a triangular splint wound with absorbent cotton and dipped into a solution of bichloride of mercury, or by plates inserted on each side of the suptum and controlled by ingeniously arranged screws. He gives the preference to the former. Asch also employs a hard-rubber tube, with numerous small perforations to afford drainage, to be worn for a considerable time until the parts are healed.
- 5. Employment of Pins .- In deflection of the cartilaginous portion of the sæptum, J. B. Roberts, ‡ of Philadelphia, makes use of pins for the purpose of holding the deflected portion in place after the resiliency of the sæptum is overcome by incising it with a knife. He makes a long incision through the sæptum, from back to front, along the line of deviation or projection. He then passes about two thirds of the length of a long steel pin through the sæptal cartilage of the normal nostril a short distance above and in front of the incision. Pressing the end of the nose and sæptum into proper position, he brings the head of the pin close to the anterior part of the sæptum, thus causing the portion lying in the occluded chamber to lie across the incision and adapt itself lengthwise along the surface of the sæptum beyond the incision. The pin is then pushed in to the head, and its point is thus deeply imbedded in the soft tissues of the sæptum and upper and posterior part of the occluded chamber. Two pins are often needed to correct the deformity. In such cases Roberts usually inserts the second one, not from the mucous surface within the nos-

tril, but from the cutaneous surface of the dorsum of the nose just below the nasal bone. The pins are left in position two weeks. The operation, although possessing the advantage of simplicity and effectiveness, will be useless unless the incisions are very free, so as to take away all resiliency of the cartilage.

6. Fracturing the Sæptum by Means of Comminuting Forceps.—Two years ago (June, 1891) I presented for your consideration a new form of forceps for correcting deviations of the sæptum, which I had had constructed about a year before, and which I have used since that time with very great satisfaction. My forceps consists, as you know, of a male and female blade, the female blade being fenestrated and the male blade fitting into this fenestrum loosely so as not to cut the tissue on the employment of pressure.\* The great difficulty attending the use of flat forceps, such as Adams's, is that it only partially corrects the deformity. It merely presses the sæptum up to the median line, and does not fracture it or sufficiently overcome the elasticity to prevent the sæptum from springing back to a greater or less degree after the pressure is removed.

Before undertaking the operation of correcting a deflected sæptum it is necessary to decide as to the advisability or necessity of the operation. Not all sæpta deflected from the median line require straightening, for the functions of the nose may not be sufficiently interfered with to require it. The first thing to determine is the amount of nasal obstruction, and whether each nostril is capable of admitting half of the normal respiratory current. One nostril may be sufficient to admit more than the normal amount of air required, or there may be sufficient space for respiration to be entirely carried on through that nostril; but the operation will be none the less required if the other nostril can not transmit half of the air respired. When no operation is necessary on account of nasal stenosis, it may, however, be necessary on account of pressure which may exist between the deflected portions and other parts of the nasal passage. In some instances nostrils obstructed by spurs, ridges, enchondromata, or exostoses of the sæptum will, when these are excised, be rendered sufficiently free for respiration, and at the same time all pressure will be removed. In such cases no operation for the moderate amount of deviation that may exist in the sæptum will be necessary.

Having determined the necessity of correcting the deviation of the sæptum, our first consideration is to place the cavity of the nostril—that is, the sæptum and the turbinated bodies on the concave side of the sæptum—in a normal condition. It is a common experience to find the turbinated body and also the turbinated bone very much hypertrophied so as nearly to fill the concavity, and in many instances so as to cause more or less stenosis of that side. Although in some instances not sufficiently enlarged to produce any obstruction of the nostril while widened by the deflection, they may none the less be large enough to

<sup>\*</sup> Since I published the description of my forceps, I notice that T.

Smith has described a similar instrument, which is illustrated in the
second edition of Greville MacDonald's Discusses of the Nose, London,

completely obstruct the passage when the sæptum is placed in the median line. The removal of this condition of hypertrophy is therefore called for before the straightening of the sæptum is undertaken. On the convex side we frequently find spurs and exostoses, rendering the sæptum abnormally thick at the angle of deflection. These are also to be removed and the sæptum reduced as far as possible to its normal thickness before the straightening is attempted. It is not possible in all cases, however, to reduce the sæptum to its normal thickness before the operation. This is especially the case in sigmoid deflections. In such instances the angular projections have to be removed after the sæptum has been straightened.

The fears entertained by many operators, and especially by the earlier operators, lest the laying bare of a considerable portion of the sæptum by the removal of spurs, ridges, exostoses, and enchondromata would lead to ulceration of the surface, because of the removal of so large a portion of the mucous membrane, are entirely groundless, for in no instance have I found a necrosis of the bone to take place, even after quite extensive destruction of the soft parts, so long as the soft parts covering the opposite side of the sæptum were intact. The sæptum receives quite sufficient nourishment from the nutrient vessels of one side to prevent any such result. This is true not only of the osseous portion, but also of the cartilaginous portion of the sæptum. The plan adopted by the earlier operators of turning back the mucous membrane and the perichondrium before the excision of the cartilage was entirely unnecessary, and the projecting angles of the cartilage can be sliced off with a knife ad libitum, so long as the wound is afterward maintained in an aseptic condition; the mucous membrane readily and kindly spreads over the denuded surfaces leaving no traces of the operation. One thing to be avoided, however, is destruction of the tissues with the galvanic cautery. This will almost always leave a mass of cicatricial tissue behind it, which will not be replaced by normal mucous membrane, but which will form a surface for the accumulation of dry crusts, secretions, etc.

The great desideratum in the correction of a deviated sæptum is to overcome all elasticity of the tissues that would tend to draw it back again. The failure of Adams's forceps and all similar forceps to meet this desideratum led me to devise these fenestrated forceps, by which we can not only bring the sæptum up to the median line, but can force the deflected portion past the center to overcorrect the deformity, so to speak, sufficiently far to overcome the elasticity and so break up the sæptum without laceration of the soft parts that it can be held in any position desired until the parts reunite and become thoroughly ossified. In the correction of deformities of the triangular cartilage in many instances, particularly if the cartilage is thick, it can be sufficiently comminuted to remain in place after having been held there for a length of time by a supporting dressing. In the majority of cases, however, it is advisable to overcome the elasticity of the cartilage by means of incisions at the most salient point, according to the extent of the deviation. These incisions may be made either with a bistoury or with cutting forceps, such as

those proposed by Asch or by Steele. The latter instruments, however, cut entirely through the sæptum, and when the sæptum is forced over to the median line the cut surfaces frequently project somewhat irregularly and therefore present an uneven surface on healing. I have found it far better to cut through the cartilage from one side, leaving the mucous membrane of the opposite side intact so as to act as a splint to support the fragments. In order to accomplish this with the least liability of cutting through it, I have frequently employed a bistoury. By placing the finger in the opposite nostril one can detect the proximity of the knife to the finger, and by exercising due care can cut the cartilage entirely through in one or several directions, as desired, without cutting through the mucous membrane on the opposite side. To accomplish this in an easier and quicker manner, however, I have modified the cutting instrument of Steele by placing a set-screw between the blades so as to regulate the distance by which the blades are separated when the instrument is closed. The distance at which the blades are held apart can be very accurately regulated by this screw, so that the cartilage can be cut through without wounding the mucous membrane on the opposite side. It is advisable that the cutting of the cartilage be done from the convex side so that the retaining dressing which should be placed on that side may cover the wound, which can thereby be maintained in an aseptic condition, the opposite nostril requiring no dressing whatever. In those cases in which the cartilage is best held in place by Roberts's pins I adopt this method of making the incisions with the happiest results.

The employment of the punch for the removal of the angular portion of the cartilage I wish also most earnestly to condemn. By its use we simply cut away a deformity which we should correct, and leave a hole through the sæptum in which crusts and secretions constantly accumulate, thus becoming a lasting source of irritation.

In correcting deflections in the osseous or osseo-cartilaginous portion we must carefully determine the amount of bending the sæptum will require in order to force it into place. The blades of the forceps are then set by the screw in the shank so as to pass into each other sufficiently far to accomplish this object. The blades of the forceps, which are separable, are introduced separately, the female, or fenestrated, blade on the concave side, the male blade on the convex side. They are then locked, as in the case of an obstetrical forceps, and carefully forced together. Sometimes it may be necessary to make a slight rotary motion in order sufficiently to comminute the sæptum, but care must be exercised lest we thereby lacerate it. The instrument, as will be seen from the illustration (Fig. 1), may be used with a number of blades of different sizes that fit into the handle.\* The blades should be selected according to

<sup>\*</sup> But two pairs, the largest and the smallest blades, are represented in the cut. Fitting into the same handle are represented a pair of blades for Steele's cutting forceps, together with the smaller cutters that fit into the blades. A pair of blades of Adams's flat forceps are also added to the set. These also fit into the universal handle and are frequently found serviceable after the employment of the comminuting forceps. These instruments are made for me in a very superior manner by George Tiemann & Co., of New York city.

to enter, the blades can be separated and moved to one on the sæptum at the point where the bleeding takes place.

down.

In many cases a twenty-per-cent, solution of cocaine thoroughly applied will be sufficient to render the operation painless, especially with the use of a little chloroform just at the time of fracturing the sæptum. In instances where the patient is hyperæsthetic or nervous, and especially in cases where cocaine will not produce complete local anæsthesia, general anæsthesia is required.

After the operation has been performed, whether it be the incision of the cartilaginous portion or fracturing of the osseous portion, the sæptum should then be placed in the median line. I usually employ a small nasal spatula (Fig. 2) that I have devised for this purpose.

A variety of means has been employed for holding the sæptum in place after the operation, but the plan that I have found to give the most satisfaction to myself and cause the patient the least inconvenience and discomfort is the use of plugs made by wrapping wool or cotton around a small metal plate. The size of the plug can thus be adapted exactly to the size of the nostril and hold the sæptum in precisely the position desired. The size and shape of the nostrils vary so greatly in different persons that to have ready-made plugs adapted to each case the surgeon would be required to supply himself with a very large number of different sizes and shapes, whereas by this method this necessity can be easily obviated. Thus aside from the utility of the method, it becomes a matter of practical convenience. It matters little what metal is employed, for the reason that the cotton-cover protects it so thoroughly that it is impossible for the metal to come in contact with the tissue so as to produce any irritation whatever. The only inconvenience experienced by the patient is from the obstruction of the nostril; but this is of slight importance, for the reason that the other nostril remains free and unobstructed.

Before the introduction of this dressing every aseptic precaution should be taken. Previous to operating I usually cleanse the nostril thoroughly with a saline solution of bichloride of mercury, in the proportion of 1 to 5,000. After the operation the nostrils should be cleansed with the same solution, or it may be used a little stronger until the ruary 7, 1894.

the amount and kind of deviation. If deflection of the bleeding is arrested. It is very rarely that continued sæptum is greater in the vertical direction than the length bleeding to any annoying extent occurs. When it does of the blade which the aperture of the nostril will permit take place, however, it can be arrested by exerting pressure

> After the hæmorrhage has ceased and the nostril has been thoroughly cleansed with this solution, the dressing is inserted. Before the dressing is introduced, iodoform is freely applied to the nostrils and the dressing dipped in a solution of bichloride of mercury, thus making the nostril as nearly aseptic as possible. The dressing may be left in situ for four or five days; at the expiration of that time it

side and a wider portion of the sæptum grasped and broken is generally necessary to change it. This can be done without any discomfort to the patient by the use of a small amount of chloroform. Again the nostril should be anæsthetized with cocaine, cleansed with the bichloride solution, and dusted with iodoform before reinserting the plugs.

It being necessary in many instances, as we all know, that the parts be held in position for a considerable time to insure their remaining in the proper place, I frequently instruct the patient, after the swelling and soreness have subsided and the soft parts are well healed, to make and insert for himself daily a fresh plug of the proper size. The introduction of the plugs is facilitated by smearing them with carbolized vaseline, which by this time is ordinarily all that is required in the way of an aseptic. The nostril is to be cleansed thoroughly, of course, each time the plug is

The variety of conditions that we meet in the correction of all forms of deviated sæpta makes it impossible to adopt any one method to the exclusion of others. But I can unhesitatingly say that in all operations for correcting deviations of the osseous and osseo-cartilaginous portions of the sæptum the method of correcting the deformity by fracturing the sæptum with my comminuting forceps, with the method which I have described of holding the sæptum in place after the operation, has been in my hands superior to all other methods and has been attended with most excellent results.

### CŒLIOTOMY FOR BILATERAL PYOSALPINX. FOLLOWED FOUR DAYS LATER BY APPENDICITIS. OPERATION. RECOVERY.\*

By FREDERICK HOLME WIGGIN, M. D.,

PRESIDENT OF THE SOCIETY OF THE ALUMNI OF BELLEVUE HOSPITAL; SURGEON TO THE CITY HOSPITAL, GYNÆCOLOGICAL DIVISION.

A. D., nineteen years of age, an unmarried woman, was admitted to the uterine service of the City Hospital in November, 1893. The family history was bad. The patient began to menstruate at twelve years of age; it was of the regular monthly type. She had pain at the beginning of the period, which ceased when the flow was established. She was delivered in August at the Maternity Hospital. Regarding her present trouble, she stated that she had had severe abdominal pains with marked tenderness over both ovaries, associated with

<sup>\*</sup> Read before the Society of the Alumni of Bellevue Hospital, Feb-

backache and headache. Her temperature ranged from 101° to 102°. Examination per vaginam revealed an enlarged and tender uterus, retroplaced and fixed; also a lacoration of the cervix. Both tubes were enlarged, especially the left. A diagnosis was made of endometritis and double pyosalpinx, and curetting and colliotomy for removal of the diseased tubes were advised. On November 27th, her general condition having improved, and her temperature having fallen to 99.5°, the operation was performed. The uterus was first curetted and packed with iodoform gauze, after which the abdomen was opened. The uterus and tubes were found firmly bound down by strong adhesions, the breaking up of which caused very free hæmorrhage, which was controlled, after removal of both tubes and oyaries, by the liberal use of hydrogen dioxide. Both tubes were found to contain pus. The ovaries were degenerated and cystic. The abdominal cavity was filled with hot salt solution (0.6 per cent.) and the wound closed without drainage. The patient did well, had little nausea, and took nourishment; the bowels moved satisfactorily, and the temperature ranged from 99° to 100.4° from the time of the operation till December 1st, when she had a chill, and a rise of temperature to 104°. Her pulse rose to 160 at this time, and she complained of pain in the abdomen, and was restless and irritable, and had nausea and diarrhea. The wound showed no sign of infection, and had closed by primary intention. Five grains of acetanilide and one grain of citrate of caffeine reduced the temperature to 101.2°; the nausea passed off and the patient had a good night. On December 2d there was marked tenderness and pain over the appendix. There was still no appearance of infection of the wound, but to make sure of this the sutures were removed. No pus was found, and examination per vaginam was negative. The temperature varied from 100.6° to 103°, the pulse from 140 to 180, and the diarrhea continued. Her condition was the same on December 4th—the temperature, 101° to 102.8°; pulse, 126 to 140. The following day she had incontinence of urine and fæces; the temperature was 101.4° to 103.8°, and the pulse 124 to 142; there was also marked tympanites. On December 6th, as the patient was going from bad to worse, and tenderness and fullness on the right side were more marked, it was determined to open the abdominal cavity over the site of the appendix. The patient was anæsthetized and the peritonæum opened, when five or six ounces of fætid pus escaped at once. Examination showed the abscess cavity to be shut off from the general cavity by adhesions, which were not disturbed. The cavity was washed out with hydrogen dioxide and lightly packed with iodoform gauze. There was no connection between the abscess and the original incision. Eight hours after the operation her temperature had fallen to 99.4°, and the pulse to 128. The next day she was doing well. The abscess was washed out with hydrogen dioxide and an iodoform-gauze drain inserted, and this treatment was continued daily till December 10th, when, as there was no pus, the drain was omitted and the cavity was allowed to collapse, the wound being gradually drawn together by adhesive strips. It was noted on December 20th that the patient was rapidly gaining in strength, and that the cicatrization of the wound was nearly complete.

This case teaches the folly of delaying reopening the abdominal cavity if a cœliotomy is followed by evidence of septic infection, because we may be afraid that the infection is general and that the operation is therefore almost hopeless. In the second place, it shows that we should not be deterred because the patient's general condition is bad. In the case just reported the operation should have been performed four days before it was, but the pulse of

180 made me hesitate, as I was afraid that the patient would not bear the anæsthetic. With the patient's condition not improved by the delay, the anæsthesia, which lasted only ten minutes, was well borne, her pulse improving while under its influence, and her hopeless condition was relieved by my finding and removing the cause of her sepsis. It is reasonable to believe that in breaking up the adhesions in the primary cœliotomy, the appendix had been injured, and that this may be oftener the cause of sepsis after these operations than we are at present aware. It is not uncommon to find in the dead-house or dissecting room the appendix adherent to the right ovary.

In conclusion, I hope that this case will lead others to have the courage of their convictions.

55 WEST THIRTY-SIXTH STREET.

#### CIRCUMCISION.

THE LAST FIFTY OF A SERIES OF TWO HUNDRED CIRCUMCISIONS
BY B. MERRILL RICKETTS, M. D.,

On February 9, 1892, I read a paper before the Cincinnati Medical Society the title of which was One Hundred and Fifty Circumcisions and the Lessons they Teach. Since that time I have done an additional fifty, for various causes, in persons from eighteen months to forty years of age. Thus I am now like David coming before Saul with the captured Philistines: "I could bring, had I preserved them, two hundred prepuees as evidence of my attack upon the Christians." I do not care to recapitulate or make any special quotations from that paper, as my object is to speak directly upon a few advantages I have found in making the operation during the last two years.

In that paper I condemned the use of scissors in work of this kind. I wish to say that I was not familiar with the use of shears. The advantages that shears have over scissors is in their firmness. They do not yield in the least, and if sharp will cut the skin smoothly, without injury sufficient to prevent primary union. The shears that I use are the ordinary nickel-plated tailor's shears, with blades eight inches long and an inch wide, tapering down to a point. They are to be used after the prepuce has been transfixed and divided upon the dorsum, after the method of Cloquet. The skin upon either side is held and pulled up with two forceps, while the skin is divided from above downward with one stroke of the shears. If there should be any small points of cellular tissue to be removed, it can easily be done with the shears alone. A suture of catgut is taken through the upper and under skins upon the dorsum at the point where the skin has been transfixed, a double knot is made, and one end left about three inches long. A continuous suture is made down upon the left side under the frenum and up the right side, where the two ends are connected. This is done after the bleeding has been checked by hot water or pressure; when there is no bleeding a piece of cheese cloth about five inches square and of several thicknesses, with a small hole in its center to allow of urination, is wrapped about the organ and

Systemic Indications.

2. Seminal emissions. 3. Enuresis.

6. General nervousness.

made secure with a soft cotton string. Ordinarily this dressing does not have to be changed until union is completed, unless the patient should be careless and cause it to become soiled. The beauty of this dressing is that it is not inconvenient, and does not very often require changing. The catgut sutures become soft and disorganized, so that it is never necessary to remove them. I have found that it is not necessary to use any kind of an anæsthetic where the prepuce is short, requiring nothing more than the median incision. I have thoroughly demonstrated that a number of boys from eight to fifteen years of age can have this incision made with but slight pain. This is done by carefully inserting a knife to the point of transfixion, at the same time diverting the mind and making the incision with one quick stroke. This once done, there is only a slight burning sensation, which amounts to but little. With children under three years of age it is best to make a circumcision as rapidly as possible without the use of any kind of an anæsthetic. Wounds made in tissue that has been anæsthetized by the subcutaneous injection of cocaine or the local application of rhigolene, ether, chloroform, menthol, or anything of the kind do not heal so rapidly as when made without their use. In cases where there is an adherent prepuce, a local application of cocaine will relieve the pain from the abraded surface, but will not prevent the pain-I mean when not used subcutaneously; therefore I would most earnestly advise that this and the other minor operations in children under three years of age be done without subjecting them to the risks of either ether, chloroform, or any of the local anæsthetics. These are the advantages that are to be obtained from doing circumcisions in early childhood. Then, too, in the majority of cases of long prepuce, if the median incision is made early in childhood, the absorption of the flaps by the time the patient becomes twenty years of age has been almost enough to obliterate them-that is, a short prepuce at the age of twenty, rendering the removal of the flaps necessary, can be avoided if a median incision is made upon that person during infancy.

In children where the prepuce is short and nothing but the median incision is required, it is not necessary to use any kind of a suture, otherwise ether or chloroform would have to be employed. Then, too, I have found in cases of short prepuce at the time of birth that if the adhesions are broken up and the prepuce is frequently retracted, there is a small percentage of cases that will not require any kind of surgical interference at the age of puberty. Thus the glans is not always covered at the time of puberty by a prepuce which barely covered it in infancy.

As to the use of silkworm gut, that is the most advantageous material to use, if the patient can be under the operator's constant supervision. There is no possibility of the wound being infected from such material, and I would urge its use where anything but catgut is to be used. Occasionally we are called upon to operate when we are not to see the patient again; under these circumstances the catgut suture would be preferable; but where there is any doubt as to the quality of the catgut, certainly silkworm gut should be given the preference.

The indications for the operation are local and systemic:

1. Onanism.

4. Dysaria.

5. Retention.

7. Impotence.

8. Convulsions.

9. Hystero-epilepsy.

Local Indications.

- 1. Hygienic.
- 2. Phimosis.
- 3. Paraphimosis.
- 4. Redundancy.
- 5. Adhesions.
- 6. Papillomata. 7. Eczema { acute.
- chronic. 8. Œdema.
- 9. Chapere.
- 10. Chancroid. 11. Cicatrices.
- 12. Inflammatory thickening.
- 13. Elephantiasis.
- 14. Nævus.
- 15. Epithelioma. 16. Gangrene.
- 17. Tuberculosis.
- 18. Preputial calculi.
- a. Hip-joint disease.
- b. Hernia.

In conclusion, I would say that, so far as I have been able to determine, there has been but one person of the two hundred upon whom I have operated who has regretted having had the operation of circumcision done.

"THE TRINIDAD," 137 BROADWAY, CINCINNATI.

### AN ANTISEPTIC POWDER.

By ALBERT PICK, M. D.,

BOSTON,
MEMBER OF THE MASSACHUSETTS MEDICAL SOCIETY, ETC.

THE number of the Journal of January 27, 1894, published a formula of an antiseptic powder used by Lucas-Championnière, of Paris (France). It is really more a deodorized iodoform preparation than an efficient antiseptic powder, as the antiseptic properties of iodoform have been proved to be very doubtful.

In connection with the above I take the liberty to publish a formula of an antiseptic powder which I have been in the habit of using, with very satisfactory results, wherever usually iodoform is employed. The formula consists:

R Hydrargyri chlorid. corros.... gr. 1/5 (or gr. 1/3); Acidi boric..... 5 j; Acidi tannici..... gr. x; Saech, lact..... q. s. ad 3 ij.

M. Sig.: Antiseptic powder.

A fifth of a grain of corrosive sublimate in this mixture gives a powder of the strength of 1 to 5,000, and a third of a grain, 1 to 3,000.

In preparing this powder care must be taken by the druggist to mix the sublimate very gradually and thoroughly with the sugar of milk, and then to add gradually the other ingredients, so as to be certain to obtain a uniform distribution of the bichloride in the mixture.

This mixture gives a more reliable antiseptic powder than any iodoform preparation and has no odor whatever.

Its strength is either 1 to 5,000 or 1 to 3,000 of corrosive sublimate, and if even a whole ounce of it (1 to 5,000) should be used at one time, which of course will never happen, only a tenth of a grain of sublimate would come in contact with the dusted surface. If even one fourth of this be absorbed (one fortieth of a grain) in an adult, no harm can result. If a small quantity is used it may be employed with perfect safety in the strength of 1 to 3,000 or 1 to 4,000 (an eighth or a sixth of a grain of sublimate to the ounce of the other ingredients).

Its untoward action, as regards intoxication, is, therefore, not more objectionable than that of iodoform, while its advantages over the latter are many. The boric acid and sugar of milk used as vehicles are both mechanically protective as well as antiseptic. The sugar of milk also prevents the deterioration of the bichloride. The tannic acid may be omitted whenever its desiccating or styptic action is not wanted.

I trust that some of my esteemed *confrères* who have an opportunity to try it extensively in surgical practice will do so, and let us hear about the results.

737 TREMONT STREET.

### STRICTURE OF THE ŒSOPHAGUS.

 $\begin{array}{cccc} & \text{DIVISION} & \text{AND} & \text{DILATATION} \\ \text{AFTER} & \text{GASTROSTOMY} & \text{AND} & \text{ESOPHAGOTOMY}. \\ & & \text{TESTIMONY} & \text{AS} & \text{TO} \end{array}$ 

THE VALUE OF ABBE'S STRING METHOD OF DIVISION.

By W. J. MAYO, M. D.,

ROCHESTER, MINN., PRESIDENT OF THE MINNESOTA STATE MEDICAL SOCIETY; MEMBER OF THE STATE BOARD OF HEALTH; SURGEON TO ST. MARY'S HOSPITAL.

H. W., aged three years, Amboy, Minn. Admitted to St. Mary's Hospital, Rochester, Minn., on October 5, 1892, with the following history given by her mother: One year previously the child accidentally swallowed caustic lye. For four weeks she was very sick, then gradually improved for several months, although totally unable to swallow solid food at any time. During the last six months she has had great difficulty in swallowing liquids, and has regurgitated from the œsophagus more than half of the nourishment taken.

Examination.-She is now emaciated to a considerable degree. Upon being given two ounces of milk it was drank with avidity, but nearly all of it was regurgitated. The dilated esophagus above the stricture holds over four ounces of fluids. Bougies were inserted through the pharynx into the esophagus, but were completely arrested at its lower end, while careful search of the face of the stricture with a number of whalebone bougies, under anæsthesia, failed to pass the stenosed portion. At intervals of four days this search was continued, but without result. While undergoing these repeated examinations the child became much better and able to retain a larger proportion of liquid nourishment, and improved visibly. Proper manipulation was much interfered with by the short, sharp curve of a child's pharynx and its small size; therefore external esophagotomy was urged upon the parents to permit of more direct access to the parts involved. This was declined, and the little girl was taken home at the end of two weeks.

On July 19, 1893, the child was readmitted to the hospital. The slight improvement had been of short duration, a gradual closing of the small channel had taken place, and for the past four weeks it had been nearly if not quite impermeable, so that the little patient had been nourished entirely by rectal enemata.

She was emaciated to a most marked degree. Careful search, as before, utterly failed to pass the stricture. External œsophagotomy, with the hope of finding a way through the damaged esophagus, did not promise the rapid relief that the child's nutrition demanded; therefore, on July 20, 1893, in the presence of Dr. Daniels, Dr. Stinchfield, and others, I performed gastrostomy after the method of Fenger, the incision being made as high up and as close to the median line as possible, to permit of retrograde dilatation. This method was chosen as permitting more direct and easy access to the cardiac orifice of the stomach in place of that of Hacker or that of von Witzel, which are far superior as to the preventing of leaking from the fistula. but also present greater obstruction to intragastric manipulation. The child was now well nourished through the gastric fistula, and twice a week the lower face of the stricture, which was at the diaphragmatic opening, was carefully searched for an outlet. On two occasions the finger was introduced through the fistula into the stomach and used as a guide for the probe, the patient being anæsthetized. The dilatation of the fistula necessary to introduce the finger in so small a subject greatly increased the leakage through the gastric opening, and the child again began to fail from the inability of the stomach to retain nourishment.

On August 25, 1893, in the presence of Dr. Linton, Dr. Phelps, and others, left external œsophagotomy, at a low point in the neck, was performed by my brother, Dr. C. H. Mayo, and a bougie introduced by him through this opening and pressed against the stricture, pushing it downward into the stomach and holding it steadily. With a finger in the stomach, careful search now enabled me to pass a long malleable German-silver probe from the stomach through the stricture and out of the esophageal fistula in the neck, and a heavy double strand of braided silk was drawn through the channel, having an end out of the opening in the esophagus and also out of the gastric fistula. The stricture was about three quarters of an inch in length, as nearly as could be ascertained. By using one strand to cut the tissues, after the method recommended by Dr. Robert Abbe, while knots were tied on the second strand and pulled into the obstruction to keep the stricture tense, the opening was greatly enlarged. This method of Abbe's was of the greatest value, and had but one disadvantage-that of cutting the edge of the gastric fistula when drawn taut. This was in part obviated by holding the lower end of the cutting thread in the bite of a forceps held on a plane with the stricture from within the stomach. Knots on the second thread, to render the strictures tense, were equally good and easier of execution than pushing bougies from below into the small opening, as recommended by Abbe. During the succeeding month, at intervals of four days, this process of division was carried on, and perforated shot clamped upon the thread were drawn through to assist in the dilatation, as they readily followed the tortuous passage. Bougies then became permissible, inserted first from the neck and later through the mouth. In five weeks the threads were removed and dilatation was carried on with olive-tipped whalebone bougies made for the purpose. A sister of the little patient was taught to pass the probes, and the child was discharged in two months in a good general condition and able to drink milk readily and to take chopped meat and bread with but little effort. The œsophageal fistula had spontaneously closed, and the gastric opening, after being touched with the Paquelin, was nearly cicatrized.

The New York Polyclinic.—At the request of the class, Professor Edward R. Palmer, of the University of Louisville, lectured at the Polyclinic on March 29th on The Sexual Relation.

### A BRAIN CYST,

THE RESULT OF INJURY, CAUSING APHASIA, HEMIPLEGIA, ETC.

EVACUATION; COMPLETE RECOVERY.

By C. H. MAYO, M. D.,

ROCHESTER, MINN., SURGEON TO ST. MARY'S HOSPITAL; MEMBER OF THE MINNESOTA ACADEMY OF MEDICINE.

On June 30, 1893, Miss O. S., aged eleven years, was thrown from a wagon in a runaway. The child was picked up unconscious, bleeding freely from the nose, and while being carried to the house had a severe vomiting spell. There was a small scalp wound on the anterior part of the left parietal bone, while about the right eye, cheek, and temple there were extensive ecchymosis and swelling. Consciousness not returning, she was nourished the first week by rectal enemata; from the second week on she was able to swallow small quantities of liquid nourishment. There was complete right hemiplegia; the eyes were fixed in an upward direction, the left pupil being the more dilated. On the fifth day there were twenty-five convulsions, and these were continued for a week, becoming less frequent each day. She remained in a comatose condition for about six weeks, when she apparently began to notice things with her eyes. Urination and defecation were involuntary following her injury. In this condition and emaciated to a skeleton she was referred to my care by Dr. O. Way, of Claremont. Her symptoms were indicative of a severe lesion about the left fissure of Rolando extending down over the speech center. On August 18th I operated upon the patient at St. Mary's Hospital, Dr. A. F. Kilbourne, of the Second Minnesota Hospital, Dr. O. Way, of Claremont, and others being present. The skull was opened by the trephine and rongeur forceps, exposing an area two inches by an inch over the left fissure of Rolando. The dura bulged into the opening and did not pulsate until a considerable area of bone was removed. On incising the dura, four ounces of a clear watery fluid were discharged, and upon opening up the dura freely the whole left frontal lobe was seen depressed; at the region of the Rolandic area this depression was over an inch from the skull. The fluid was between the arachnoid and the dura. The cerebral tissue expanded to but a slight degree, leaving a large cavity. There was no sign of fracture in this region or beneath the scalp wound, although the dura was closely adherent to the skull. Catgut strands were placed so as to project into the cavity and extend out of the scalp wound, and the membrane was closely sutured with the same. The scalp wound was then closed with interrupted sutures of silkworm gut without reimplanting the bone chips. Her appearance was much better the day following the operation and her recovery was very rapid. At the end of the first week she could say "No" and "Yes," and those were the first articulate sounds she had made since the accident. She could also move the right arm and leg. Words came slowly and hesitatingly but correctly, and after three weeks she was able to sit up and call for food, naming the different articles wanted. Four weeks subsequent to the operation she was discharged from the hospital, and three weeks later she was able to walk across the room alone and talk quite freely. She has no recollection of events from the date of the accident to that of the operation, and but little during the week following. The condition was probably one of degenerative cyst resulting from the severe injury. Chloroform anæsthesia was employed.

Note.—A letter from her mother received December 20th says that the child plays about with other children and that she considers her perfectly recovered.

### THE USE OF ANTIPHONES.

By E. W. SCRIPTURE, Ph. D.,

Sensory irritability during sleep often seriously interferes with the sleep and work of the patient without being considered worthy of inquiry or treatment by the physician. Especially noteworthy is the fact that the use of antiphones is almost unknown, although so many individuals are constantly disturbed by noises in the house, traffic in the streets, and the clock bells on churches. Four years of experience have proved my ability to obtain sound sleep by means of antiphones, whereas before their use (and now at any time when they are omitted) comparatively little sleep was to be obtained. After trying various substances, I was led to using antiphones made of sealing wax in the following way: The stick of wax is warmed over the gas flame, and a sufficient quantity is pressed off between the thumb and finger. This is placed in the entrance to the external meatus. In order to make such a fit that no sensations of touch are produced when the head is placed on the pillow, the tragus is pressed over it for an instant, and the end of the index finger slightly loosens the top and the bottom of the plug in the ear. Each morning the antiphones are thrown away.

The selection of the wax is a vital matter. If the wax melts at a high point, it will burn the fingers and the ear; if it passes from solid to liquid without a viscous stage, it can not be molded; if it is too hard, it will cause pain in the ear; if too soft, it will seize the fine hairs and pull them out. Numerous trials have led me to select Dennison's Am. Expr., No. 2, while in America, and Packet-Lack in Germany (American package-wax is seldom viscous). The subjective noises may disturb the patient on the first occasion, but they will soon become unconscious.

## A CASE OF FRACTURED RIB AS A RESULT OF A FIT OF VIOLENT COUGHING.

By H. J. SCHERCK, M. D.,

VISITING SURGEON TO CHARITY HOSPITAL, NEW ORLEANS; CHIEF OF CLINIC, CHAIR OF SURGERY, TULANE MEDICAL COLLEGE; FELLOW OF THE SOUTHERN SURGICAL AND GYNÆCOLOGICAL SOCIETY.

About ten days since I was called suddenly to an old man whom I had been treating for some time for a severe chronic bronchitis. Upon my arrival, I was informed that during a severe paroxysm of coughing he had felt something snap on his right side; upon examination I found a complete fracture of the ninth rib in the axillary line.

The patient is a German, aged about seventy-two years, and from the extreme brittleness of this bone it might be in truth termed "a pipestem rib."

I find in looking over the literature that such cases of fracture are extremely rare—in fact, I can find no case resembling mine exactly. I have therefore considered it of sufficient interest to report to the profession.

145 CANAL STREET.

The Death of Dr. Brown-Sequard.—It is announced that Dr. Charles Edouard Brown-Sequard, the noted Paris physician and physiologist, died on Monday, the 2d inst., at the ago of seventy-seven.

THE

### NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

D. APPLETON & Co.

Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, APRIL 7, 1894.

#### IN THE WAKE OF THE GRIPPE.

Four years of pandemic, of invasion by a hydra-headed plague, of subjection to the assaults of one of the most intense nerve-poisons known to mankind, and in what state of vigor does the community find itself? That many old hulks have foundered in the storm, that many ill-built barks have been towed with difficulty into port, is evident to all. But what of the gallant ships which, stanch and buoyant, bravely rode out the gale? Are they the worse for the contest, or are they as trig and strong as ever to meet again the vicissitudes of life's troubled sea? That the marks of the ravages of influenza will remain throughout life in persons who have no organic disease we can not believe. There is every reason to suppose that influenza itself is a self-limited disease; that, unless speedily destroyed by its subtle poison, the well-balanced human organism will in time either expel or destroy the invading "influence." The influenza poison seems to be incapable in itself of working deep-seated organic changes in the tissues. It produces grave disaster, on the one hand, by disarranging through overwhelming assault the nerve functions which operate the heart and lungs; on the other hand, by giving occasion to the development of other diseases which would not else have found lodgment in the body. But that the nerve-force of the community has been left temporarily below par by the departing pandemic may be very reasonably suspected. How else can we explain the tale of numerous ununited, and apparently ununitable, fractures which are told us by the surgeon? How else may we account for the protracted neurasthenia of men and women formerly vigorous, or for the strange inco-ordination between pulse, temperature, and respiration rates observed in obstetrics and in general medicine? May we not so interpret the absence of a new fad in medicine during the past winter-indicating that even the medical crank has lost the energy to advertise himself? And has there not been a falling off in the usual number of excised ovaries exhibited before the medical societies, by which the young and confident gynæcologist was wont in former years to prove his title to chieftainship? Can it be that the remover of "appendages" has lost his nerve? Or has some vague feeling of timidity entered the confiding heart of womankind?

Unabashed, the "orificial surgeon" pursues his daily round of "operations," cutting off rectal tags for fabulous sums of gold, stretching all the sphincters within reach ("all-round work" he calls it) for every imaginable disorder of every existing organ of the body, and winding up obstinate patients with the "great American operation," the details of which he disdains to expose

to uninitiated readers of his fables. One fact, it is true, he seems to have unearthed-that an unconscious man may be stimulated to inspiration and kept breathing by repeated sudden stretchings of the anal sphincter. We desire to give even the "orificialist" his due, but this lonely fact was unearthed before the influenza depression of which we are speaking had reached its greatest intensity. Looking beyond the bounds of medicine, may we not discover in the economic world signs of deficiency of nerve-tone? Does not the strange and hitherto unexplained wave of distrust which still depresses the financial operations of civilized nations suggest a want of nervous force, a widespread lack of self-confidence among men? And is not this deficiency betrayed also in the sluggishness which our legislators manifest in facing problems of vital interest to their constituents? Surely "the world is out of joint" for the time being, and audacious enterprises must for the present be put aside in order that the nervous system of the public may find opportunity for rest and recuperation. And that future generations may not deride us for our lack of enterprise, let us write large in the literature of to-day this memorial inscription: The influenza did it.

## INTRAMUSCULAR ABSCESS FOLLOWING AN ATTACK OF GRIPPE.

AT a recent meeting of the Société de médecine et de chirurgie pratiques, the proceedings of which are reported in the Gazette médicale de Paris for March 10th, M. Diamantberger related the case of a man who had an attack of grippe accompanied with angina and laryngitis. At the end of three or four days he recovered, and, when his health was restored, went out one day to his office. He was not exposed to cold, and he did not seem very much fatigued; but that evening he complained of a severe pain in the calf of the right leg, followed by a swelling. On examination, it was ascertained that in the middle of the calf of the right leg there was a swelling of considerable size with manifest hardness of the tissues, but without change in the coloration of the skin. The swollen part had caused no alteration in the shape of this region, but it was somewhat painful, and there was a slight puffiness of the knee joint near the lateral ligaments. M. Diamantberger had prescribed absolute rest and applications of bran and water to prevent a sanguineous effusion. The temperature was normal, the general condition was good, and there was no sugar or albumin in the urine. At the end of five or six days the swelling became softened and the temperature rose to 100° and 102°. Two days after, the diseased region clearly indicated the presence of an abscess, and at the same time a small, painful swelling, red and freely fluctuating, appeared near the pronator muscles of the left forearm. The two abscesses were opened, and the patient recovered rapidly.

The history of this case, says M. Diamantberger, is interesting because of the strange nature of the complications. In his opinion, there had been a muscular rupture, aggrayated by the grippe, which had given rise to myositis in a patient predisposed to it by the bad condition of his muscles, and an effusion of blood had given rise to suppuration. The supposition of a venous rupture was admissible, as the patient's leg showed several varicose dilatations. One thing was certain, says M. Diamentberger, that, in this case, the grippe had been the cause, either directly or indirectly, of the intramuscular abscesses.

### MINOR PARAGRAPHS.

### THE NEW YORK STATE VETERINARY COLLEGE.

A RECENT act of the Legislature establishes a State veterinary college in connection with Cornell University at Ithaca, and appropriates a sum not to exceed \$50,000 for the purpose of constructing and equipping buildings suitable for the college on the university grounds. We are glad of any proper step that tends to advance either the study and teaching of veterinary medicine or the prestige of such an excellent university as Cornell; but we do not regard this action on the part of the State as proper. We quite agree with the Sun in its comments on the act. That paper says: "The well-being of domestic animals, particularly of the horse and cow, is extremely important to the community, and can hardly be preserved without the aid of qualified persons trained in the sciences and arts of veterinary medicine and surgery. But why should the State of New York, which does not maintain any school for the training of medical men to treat human beings, spend \$50,000 to establish an institution to teach men how to doctor horses and cattle?"

#### NEW JOURNALS.

WE have recently received the initial numbers of two new monthly periodicals, one of which, entitled Science Progress, is devoted to current scientific investigation. It is published in London and conducted by Mr. Henry C. Burdett, the wellknown writer on hospitals. The other is the New York State Medical Reporter, published in Rochester and edited by Dr. H. Bronson Gee.

### THE ROME CONGRESS.

It is not to be doubted that the scientific aspect of the International Medical Congress in Rome has been as gratifying as its festal features. Among these was a party in the garden of the Quirinal on Monday, followed by illuminations of various ancient ruins in the evening.

### THE AERZTLICHER ALMANACH.

WE regret to learn that the ill-health of Dr. Kállay, of Carlsbad, the editor of this very useful publication, has delayed its appearance thus far this year. It is announced that a double number, for 1894 and 1895, will soon appear.

#### ITEMS, ETC.

The Michigan College of Medicine and Surgery held its fifth annual commencement exercises in the Detroit Opera House on Thursday, March 29th. The graduating class numbered twenty-seven. An address was delivered by Dr. Edward W. Jenks.

Army Intelligence .- Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 25 to March 31, 1894:

HORTON, SAMUEL M., Lieutenant Colonel and Deputy Surgeon General, will, by direction of the President, report in person | SATURDAY, April 14th: Obstetrical Society of Boston (private).

to the president of the Army Retiring Board, at San Francisco, Cal., for examination by the board.

Infectious Diseases in New York .- We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 3, 1894:

DISEASES.	Week ending Mar. 27.		Week ending Apr. 3.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	0	0	0	0
Typhoid fever	12	2	8	3
Scarlet fever	156	13	158	15
Cerebro-spinal meningitis	0	()	0	0
Measles	350	30	318	24
Diphtheria	227	48	224	56
Small-pox	18	4	33	5

### Society Meetings for the Coming Week:

MONDAY, April 9th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medico-historical Society (private); New York Ophthalmological Society (private); Lenox Medical and Surgical Society, New York (private); Society of Medical Jurisprudence, New York; Boston Society for Medical Improvement; Gynæcological Society of Boston; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private); Baltimore Medical Association.

TUESDAY, April 10th: Medical Society of the State of Tennessee (first day-Memphis); New York Medical Union (private); Kings County, N. Y., Medical Association; Medical Societies of the Counties of Jefferson (quarterly-Watertown), Oneida (quarterly-Utica), Ontario (quarterly), Rensselaer, and Tioga (quarterly-Owego), N. Y.; Newark, N. J., Medical Association; Trenton, N. J., Medical Association (private); Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Bergen, N. J. (annual-Hackensack) and Cumberland, N. J. (annual), County Medical Societies; Fairfield, Conn., County Medical Association (annual); Northwestern Medical Society of Philadelphia; Baltimore Gynæcological and Obstetrical Society; Practitioners' Club, Richmond, Ky.

WEDNESDAY, April 11th: Medical Society of the State of Tennessee (second day); American Microscopical Society of the City of New York; Metropolitan Medical Society, New York (private); New York Pathological Society; New York Surgical Society; Medical Society of the County of Albany, N. Y.; Tri-States Medical Association (Port Jervis, N. Y.); Pittsfield, Mass., Medical Association (private); Philadelphia County Medical Society; Kansas City, Mo., Ophthalmological and Otological Society.

THURSDAY, April 12th: Medical Society of the State of Tennessee (third day); New York Academy of Medicine (Section in Pædiatrics); New York Laryngological Society (private); Brooklyn Pathological Society; Medical Societies of the Counties of Cayuga and Fulton (quarterly), N. Y.; South Boston, Mass., Medical Club (private); Pathological Society of Philadelphia.

FRIDAY, April 13th: New York Academy of Medicine (Section in Neurology); Yorkville Medical Association (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

### Retters to the Editor.

THE HOMEOPATHIST WHO "PRACTICES BOTH WAYS."

NEW YORK, April 2, 1894.

To the Editor of the New York Medical Journal:

Sir: There is no more gratifying and certain indication of the ultimate and, we hope, not very remote downfall of our sister science (?) homeopathy than the increasing prevalence of "the homeopathist who practices both ways." The editor of the New York Medical Journal, five years ago, called attention to a Judicial View of Medical Sectarianism in which Judge George C. Barrett, of the New York Supreme Court, referring to homeopathists, speaks of "their constant and clandestine resort to what they are pleased to term allopathy." To-day it would probably be difficult to find a man who professes to be a strict homeopathist, if we may judge from reports of patients of these so-called homœopathic practitioners, who are very apt to remark: "Oh, our doctor is very liberal. He says he practices both ways." Liberal indeed! Now, in the first place, when a homeopathist admits to his patients that he "practices both ways" he acknowledges the weakness and inadequacy of homeeopathy. And he probably makes the humiliating admission either from a desire to be honest or in deference to a demand for honest treatment on the part of patients no longer willing to believe that a remedy can do good only under the law of similia similibus curantur. Few of the laity possess any clear understanding of the nature of the controversy between homeeopathy and "the old school." But they have come to feel satisfied that the latter can not be altogether wrong, and they demand rational treatment. The modern homeopathist takes a new departure and meets the demand by "practicing both ways"; in other words, by professing to practice both ways, while he still calls himself a homocopathist. He may be honest and himself deceived as well as deceiving others, but I feel compelled to assert that there can be no such thing as a true homeopathist practicing both ways.

The fundamental doctrine of homosopathy is an exclusive dogma: "Like things are cured by like, and remedies acting under any other law are never curative." This construction of the aphorism similia similibus curantur is justified by numerous confirmatory assertions of the highest homosopathic authority—e.g.:

"The curative virtues of medicines depend solely upon the resemblance their symptoms bear to those of the disease."

"Even among diseases which occur in the ordinary course of Nature, it is only those whose symptoms are similar that can cure or destroy each other. This faculty never belongs to a disease that is dissimilar. From this the physician may learn what are the remedies with which he can effect a certain cure—that is to say, that he can cure with none but such as are homeopathic."

"The proceedings in Nature will teach the physician that he ought to treat disease by no other remedies but such as are homeopathic, and not with allopathic agents, which never cure the patient, but only render his condition still more deplorable." (Organon, pp. xvii, xix, Dub. ed., 1833.)

These being the teachings of homeopathy, how can a homeopathist "practice both ways"? Just as soon as a man admits the curative power of a remedy acting under any law other than that of similia similibus, he ceases to be a homeopathist. He has renounced his creed and embraced another. As well might a Baptist clergyman baptize by sprinkling as well as immersion, and say "he was very liberal and practiced both ways." It is a question of consistency. Clearly, the Baptist is

limited to baptism by immersion, and the homoeopathist to healing by homoeopathy. But as other denominations may employ immersion, so all that is good in homoeopathy may be employed in regular medicine, which knows no limitations of doctrine or dogma and seeks diligently after that which is best. Our practice is unrestrictedly eclectic. A few well-known "homoeopathists" seem to have realized the absurdity of their position, and have become members of the Medical Society of the County of New York. Is it too much to hope that another generation will have said a last good-by alike to homoeopathy and "the homoeopathist who practices both ways"?

J. MILTON MABBOTT, M. D.

#### THE OPHTHALMOMETER

NEW YORK, March 25, 1894.

To the Editor of the New York Medical Journal:

Sie: Dr. Roosa's eulogy of the Javal ophthalmometer in this week's *Journal* is so much at variance with my own observations with this instrument that I thought the results of my experience might possibly be of interest, especially as it is founded upon cases taken from general practice.

I have had my ophthalmometer about eighteen months, during which time I have used it in a hundred and forty-four cases, but simply as an auxiliary to other methods of examination. Of these cases, in only forty-five were the results obtained by this instrument found to be correct, and in these forty-five the astigmatism was generally of high degree. In the remaining ninety-nine the results were entirely wrong and misleading.

All these cases were tested under a mydriatic. In the younger patients atropine was used, while in those over twenty-one homatropine was found to answer the purpose.

As it has seemed to me that the greatest number of cases of reflex disturbances from astigmatism are associated with low degrees of that error (0.50 D. to 1.25 D.), and as it is chiefly as a means of affording relief to sufferers from these reflex symptoms that refraction is of interest to the general practitioner, I consider that the ophthalmometer is an instrument to be avoided by him. To me it seems like a clumsy, expensive, and unreliable affair, adapted only to producing a mental effect upon the patient. And I am firmly convinced, on looking over my records, that, had I relied upon this instrument to the exclusion of mydriatics and retinoscopy, I should not have had the deeply gratifying success in the treatment of the long train of reflex disturbances from eye strain which has marked my little excursion into the domain of ophthalmology.

WALTER G. HUDSON, M. D.

### CHANCRE OF THE GENITALS WITHOUT COITUS.

BOSTON, April 2, 1894.

To the Editor of the New York Medical Journal:

Siz: Having just finished reading Dr. Buckley's interesting book on Syphilis in the Innocent, I am tempted to send you an account of a case in which the infection occurred in a peculiar manner, different from any I have seen mentioned. It was of genital origin, yet innocently contracted. A child, ten years of age, was troubled with pin-worms, some of which had crawled into the vulva. The mother, who had nucous patches, attempted to remove them by wiping the parts with a soft cloth. One of the parasites clung tenaciously; the mother then expectorated upon the part to moisten it, and rubbed hard to remove the offender. Infection took place and a chance developed at the seat of the abrasion formed. Constitutional syphilis followed. The mother had been cautioned against communicating the disease by kissing, etc.

J. Forer Bush, M. D.

### Proceedings of Societies.

SOCIETY OF THE ALUMNI OF BELLEVUE HOSPITAL.

Meeting of February 7, 1894.

The President, Dr. Frederick, II. Wiggin, in the Chair.

(Concluded from page 198.)

Communication of Communication (See page 430.)

Communication of Communica

Dr. W. EVELYN PORTER said that he had had a similar case in which perityphlitis and pyosalpinx had coexisted, but the circumstances had been such that the operation had been done for both conditions at the same time. The abscess had been on the left side, the appendix had contained a fæcal concretion, and the abscess had been attached to the left tube and ovary, the appendix being so elongated as to wind around the abscess mass to the opposite side of the abdomen.

Dr. C. C. Barrows thought that Dr. Wiggin deserved much credit for his skill in diagnosis and boldness in operating on this case, for he thought very few surgeons would have done the operation. With a patient in the Trendelenburg posture, one could both see and feel the appendix through a median incision. In many cases of pyosalpinx he had found the appendix adherent, and in three cases he had found pus in the appendix, which had apparently communicated with the pus in the right Falloppian tube. He thought it should be a cardinal rule for every abdominal surgeon to carefully examine the appendix every time the abdomen was opened, with a view to its removal unless entirely healthy. It was quite probable there had been a pathological condition in the appendix before the primary laparotomy in Dr. Wiggin's case, and the necessary injury done by disturbance of adhesions might have brought on an acute inflammation of the organ.

Dr. R. A. MURRAY also thought the operator should be congratulated on his success in this case. He had seen quite a number of septic cases where the surgeon had refused to reopen the abdomen because the result was so commonly fatal. A case had been reported, he believed by Dr. Coe, of late fever in a parturient woman. About two weeks after confinement there had been a rise of temperature, associated with a swelling on one side of the abdomen. There had been no explanation of the rise of temperature until about a week later, when a consulting surgeon had decided it was due to a pyosalpinx. The abdomen had been opened, and it had been found that there was a pyosalpinx and also an appendicitis. The appendix had contained pus, which had ruptured into the ovarian tissue, producing an ovarian abscess and also an involvement of the tube. The trauma of pregnancy had apparently stirred up a latent appendicitis. When we recalled the amount of trauma incident to the Credé expulsion of the placenta, or similar manipulation of the uterus during labor, it was not surprising that such an accident should occur.

Dr. Goldthwaite said that he had operated for appendicitis only a few times, and with not very flattering success. In two of his cases the appendix had been adherent to the ovary. In one case there had been ulceration through the appendix, but the abscess cavity had been shut off from the general abdominal cavity. He had been surprised in several cases at the extreme length of the appendix. He would also congratulate the operator most heartily on his great success in this case.

Dr. PARKER SYMS said that he had seen a good many cases

where infection had occurred after laparotomy, but he could recall no instances where he had seen the abdomen reopened, although he thought it would have been desirable in several of the cases. No one could say that a curable condition might not be discovered in this way.

Bright's Disease of the Kidneys, with Special Reference to Albuminuria and Uræmia so called, including Puerperal Convulsions.—Dr. R. C. M. Page read a paper with this

title. (To be published.)

Dr. W. B. VANDERPOEL discussed albuminuria as a symptom in general. He said that the value of albuminuria as a symptom depended largely on the collateral urinary conditions, the presence or absence of casts, the specific gravity of the urine. the daily quantity, the amount of urea, and the persistency and amount of albumin. For the first clear idea of the clinical importance of albumin in the urine we were indebted to Dr. Richard Bright, in his Reports of Medical Cases, 1827 and 1831. It had long been considered sufficient to ascertain the presence of proteid matter to pronounce the case one of renal origin, probably a nephritis, and to deduce the worst prognosis; now, however, it was well known that several other proteid bodies might have existed in the urine besides albumin, each bearing its own significance, and that the presence of many or all might depend on causes widely remote from the kidneys. Some observers, notably Posner and Senator, even maintained that albumin existed at times in the urine of every healthy person, and that we should recognize a physiological albuminuria as we did a glycosuria, oxaluria, or indicanuria of like nature. Again, well-pronounced forms of renal disease had frequently been reported in which albumin had been entirely absent from the urine, constantly or intermittently. In the large majority of cases albumin certainly did accompany, and its detection afforded good ground for suspecting organic renal lesion, but there existed a large class in which no such significance attached to albuminuria as to existing conditions, whatever its prognostic import might be. This phase or type of the morbid condition was considered in a paper recently read before the Section in General Medicine of the Academy, and to this we might profitably confine our attention in this discussion.

In considering albuminuria without manifest organic lesion, we might bring under a threefold heading all the clinical varieties reported by different writers—viz., (1) simple albuminuria, (2) the uric acid or oxaluric form, and (3) the neurotic type. The term "simple albuminuria" was applicable to a large class presenting no preceding or accompanying symptoms indicating morbid disturbance of the digestive, circulatory, or nervous functions; giving no indication from uranalysis of organic renal lesion; and whose existence was only revealed accidentally through examination by the family physician or, more often, by the examiner for life insurance. These were the true functional, physiological, or chronic albuminurias. The discoverable causes were (1) dietetic, (2) exposure to cold or cold bathing, (3) muscular activity, and (4) mental strain, worry, or prolonged brain activity.

The mere ingestion of food sufficed in those predisposed, while in others an idiosyncrasy existed toward certain food articles, as eggs, cheese, buckwheat cakes, pastry, meats, etc.

The influence of exposure to cold had been clearly proved by the observations of Grainger Stewart. Under the head of "muscular activity" were included all states, conditions, or pursuits which involved any tax on the physical powers—e. g., football playing, soldiers on the march, pedestrianism, blowing of wind instruments, parturition, and exceptionally the erect posture. The influence of mental strain had been observed in business and professional men. Its influence had been more or less satisfactorily explained (1) by toxic substances in the

blood—e. g., uric acid or lime oxalate—due to diseased or perverted gastrie or intestinal function, and which caused mechanical irritation of the kidney in their exerction; (2) by a possible transudation of albumin from the renal blood-vessels, due either to changes in the caliber of the vessels or in the rapidity of the blood current depending on reflex influences, or to a plethoric condition of the blood, or to the osmotic influence of an increase of the salts of the blood or the urea; (3) by excessive disintegration of the red blood-corpuscles, adopting the theory of Dr. T. Oliver, of Newcastle, England, as to the origin of urea depending on excessive hepatic stimulation under nitrogenous-food ingestion; and (4) by an actual glomerulonephritis.

In the uric acid or oxaluric form the daily quantity of urine remained normal, but the amount of solids was materially increased, furnishing a concentrated urine, having a specific gravity of 1.022 to 1.036. The chlorides were normal or increased, never diminished as with contracted kidney; the phosphates and urea were normal or increased; casts, hyaline or epithelial, might be present. The quantity of albumin was usually small; it was most abundant early in the day and might be absent in the evening. Two factors were mainly active in producing this condition-viz., (1) excess in an insufficiently mixed diet, and (2) an inherited or acquired sensitive condition of the liver and kidneys, called the uric acid or lithæmic diathesis, which rendered them prone to functional disturbance. The causes were (1) mechanical renal irritation, due to the sharp uric-acid or lime-oxalate crystals which, if lodged, might produce a persistent albuminuria; (2) an altered blood pressure in the renal vessels, due to reflex irritation of the terminal pneumogastric filaments; and (3) chemical blood changes.

Frequently no constitutional symptoms were noticeable, but more commonly there was a dyspeptic history with pronounced nervous and circulatory disturbances, some cases presenting a rigid, high-tension pulse, warning of impending organic renal changes

In the neurotic type the cases followed or accompanied manifestations of epilepsy, chorea, apoplexy, hysteria, influenza, exophthalmic goître, and, more rarely, infantile paralysis, multiple selerosis, and the general paralysis of the insane. Puncture of the floor of the fourth ventricle near the glycosuric center would produce albuminuria, as would also lesion of the cerebral peduncles and section or irritation of the spinal cord. Direct nervous influences acting from the brain or spinal cord through the splanchnic, celiac, and renal nerve plexuses produced changes in the renal circulation resulting in albuminuria.

The speaker said there were a few types of obscure ætiology which he would not attempt to classify; these were (1) a form attending extremes of temperature; (2) a type occurring in the newly born; and (3) one occurring after anæsthesia. A nervous origin might possibly be assigned to all of these, as with a glycosuria which might present under like conditions.

The prominent clinical features presented by these albuminuric cases were worthy of our careful scrutiny, as a diagnosis from the organic form could often only be made by exclusion. In the purely functional forms the pulse-rate was usually normal and the tension feeble. When both were constantly increased we might justly consider that we had to deal with a commencing cardiac hypertrophy and arterio-sclerosis. The amount or persistency of the albumin was of little moment in determining the diagnosis. The forms usually found and alluded to as of pathological import were serum albumin and serum globulin; these were found in all albuminous urines. Other and adventitious forms, difficult to distinguish, might be associated with these. Many of the latter mingled with the prine after its secretion, and were derived from disintegra-

tion of the renal epithelium, or were due to the presence of blood, pus, prostatic or seminal fluid, etc. The microscope and clinical history would usually distinguish these adventitious forms, except in the case of mucin, a fruitful source of error. This substance Sir W. Roberts considered was present in all urines, healthy or morbid, but W. H. Washburn regarded it as of the same diagnostic import as albumin, if persistent or in large amount.

The quantity of urea was an exponent of the working capacity of the kidneys, but was influenced by the quantity of fluid consumed, kind of food, exercise, and digestive state. It should be normal in functional albuminuria. Casts originated in the renal tubules from albuminous or fibrinous exudates from the blood. They were found in most forms of renal congestion and inflammation, but why they were at times present and at others absent under the same apparent physical condition we could not say. Although usually of grave import, many cases in which they had been found had recovered, and Charcot stated that hyaline casts might exist in normal urine.

If the specific gravity was high we might safely assume that the kidneys were performing their function properly, particularly if the daily quantity of urine was normal. The daily quantity indicated the filtration activity of the kidneys and should remain normal here, influenced solely by the usual causes—atmospheric temperature, moisture, and diet.

The color of the urine varied from pale to dark or even black. These grades depended on the concentration of the urine, or were due to articles of diet, certain drugs, or abnormal products from the patient's own economy. The phosphates, urates, chlorides, and oxalates had been already considered.

The patient often presented a peculiar pallor, associated with disinclination to exercise, poor circulation, and transient cedemas of feet or eyelids. These appearances might warn us of these functional forms, although the same symptoms in a more intense degree were seen in the organic form. He always felt distrustful toward these causes, and only relaxed this feeling when the albumin had been absent from the urine for weeks or months consecutively, and that secretion had become entirely normal in other respects. Undoubtedly many cases might persist for years and never go further toward organic disease, but the natural tendency was not so benign, and he would pronounce these cases as suspicious and worthy of careful supervision and demanding a guarded prognosis.

Dr. WILLIAM H. PORTER spoke more particularly of the source of the albumin in the urine. In reference to this question he said that he had some rather radical notions. He thought it came from two sources-one of which was the filtration of the serum-albumin from the blood in the urine, and the other an excretion of an isomeric form of albumin from the blood by the epithelial cells into the renal tubules. In the majority of instances he thought that it was due to vicarious action of these epithelial cells which took up the albumin and transformed it into another type and excreted it into the urine. In that particular type which was truly an inflammatory process and where the blood-vessels had been absolutely injuredsuch as occurred with any inflammatory process-he believed that by virtue of the alteration of the chemical composition of the walls of the blood-vessels, serum-albumin passed through, as in all inflammatory processes; but if there were no inflammatory renal affection he did not believe that this non-diffusible serum-albumin would pass through a non-diffusible membrane. He thought that all the experimental evidence, pathological lesions, and clinical observations pointed strongly this way. The ureter, artery, and veins had been tied, and as a result albumin had been found in the urine; but it had been forgotten that in these experiments the nutritive activity of the kidney had been

greatly altered. This changed the function of the epithelium, and caused it, he believed, to excrete the isomeric form of albumin. Hence he thought that the albumin in the urine in the majority of instances was an excretion by the epithelial cells. In all that type of renal lesions in which the blood-vessels were most involved there was the least albumin in the urine, and in all that variety in which the blood-vessels were the least involved, except an acute and truly inflammatory process, and in which the epithelium was most involved, there was the most albumin, and it was in direct proportion to the amount of degeneration in the epithelial cells. Chemically, it was known that the serum-albumin of the blood was precipitated in an alkaline medium or in the natural fluid of the blood. Some other salts existed in the urine, but we were always warned to acidulate the urine in order to get albumin; hence, in the majority of cases, the albumin obtained in the urine was not serum-albumin. We must act upon this derived or isomeric form of albumin by an acid and convert it into an acid albumin before the heat would precipitate it.

To sum up, the experimental, pathological, and chemical evidence pointed strongly to the albumin in the urine being an isomeric type of albumin excreted from the egg-albumin and taking the place of the urea which under normal circumstances was generally excreted by the renal cells.

Taking this view of the situation, he had been led to believe there was no such thing as functional albuminuria, but that the presence of albumin in the urine always meant a certain amount of degenerative change in the epithelial cells-a pathological condition dependent upon the amount of albumin-a greater or less degree of degeneration in the epithelial cells. He did not believe, however, that the mere presence of albumin in the urine meant that the patient had Bright's disease or was going to have Bright's disease, for he believed these renal degenerative conditions were easily curable if taken at a moderately early stage and properly treated. He believed all renal conditions were secondary diseases, and he did not believe there was such a thing as a primary disease of the kidney, commonly called Bright's disease; they were all due to defective nutrition, and increased work thrown upon the kidney as a result of this defective nutrition. An acute inflammatory condition he believed was due to a sudden congestion of the renal circulation. which overstretched the blood-vessels in the glomeruli and renal tissue, and so caused direct injury to the renal vessels. If we simply removed the work from the kidney and improved its nutrition, we would very soon see these cases improve.

With reference to treatment he would say that he had very great faith in pilocarpine, and he had probably used it as much as any one here in this city. The great mistake in its use was in employing too small doses; he had never given less than three fourths of a grain, and he had given as high as two grains hypodermically, followed in twenty minutes by another grain, and had never seen any ill effects from its use in this way. When given in such large doses it not only excited the skin to activity, but also excited the liver, the intestines, and kidneys to activity; and as a result of this one obtained a forced oxidation of the by-products floating in the blood which he believed caused the uramic symptoms. He thought the reason so much discredit had fallen on pilocarpine was because it had been so frequently used as a last resort after calomel, jalap, and elaterium had been administered. Under these circumstances it would certainly cause alarming depression of the system, such as he had not observed when these other remedies had not been first introduced.

Dr. J. CLIFTON EDGAR spoke of the treatment of puerperal eclampsia. The treatment was both preventive and curative. Under the head of preventive treatment we were met with the

fact that the scientific preventive treatment of this condition was still a dream of the future, because we did not yet know the cause of puerperal eclampsia. It had been said repeatedly that there was a certain relationship between albuminuria and puerperal convulsions, yet some women having very little albumin in the urine would have such convulsions, while others having a large quantity of albumin would not have convulsions at all. In sixteen per cent, of cases of puerperal eclampsia there was no albumin whatever in the urine. It was generally believed that if convulsions occurred, albumin would appear after the first, second, or third convulsion, yet there were carefully reported cases on record where after several convulsions, and even after coma, no albumin had been found in the urine. He recalled one such case which he had seen recently at the New York Maternity Hospital, Blackwell's Island. The urine was drawn repeatedly by catheter, and as repeatedly examined by various tests, but no albumin was found. After continuing in the coma for four hours the woman died. The pathologist reported that the autopsy showed little or no change in the kidneys. From the first convulsion, occurring in the second stage of labor, to the death of the woman, the time was four or five hours.

There were said to be two clinical guides to impending eclampsia. One of these was diminution in the quantity of urea in the urine. Dr. E. P. Davis, of Philadelphia, had recently read a paper on what he had called The Toxemia of Pregnancy. As a result of five hundred and sixty-four examinations he had found that the average quantity of urea excreted by the pregnant woman was 1.4 per cent., and that after labor the proportion was 1.9. His observations had also shown that if the quantity of urea fell below 1.5 per cent. during pregnancy, treatment directed to stimulating the excretory organs would be followed by disappearance of the headache, gastric disturbances, and other toxic symptoms which might have been present. Such a guide was not of great practical importance, for laboratory experiments showed that if a quantity of urea were injected into a rabbit no toxic symptoms would be produced. There were many much more toxic substances than urea-for instance bile, which was ten times as poisonous. As a result of the experiments of Bouchard, of Paris, on autointoxication, it was found that the normal urine when injected into a rabbit was poisonous in the proportion of forty to sixty cubic centimetres per kilogramme of rabbit, and that when kidney failure resulted, one hundred to one hundred and twenty cubic centimetres were necessary to produce toxic symptoms per kilogramme of rabbit. Dr. Mary Putnam Jacobi had verified these experiments in this country with the urine of pregnant women. This was extremely interesting, for it showed that in the absence of any diminution of urea there might be kidney failure and retention of toxic material in the blood, leading to convulsions or other symptoms. Hence, our present knowledge only permitted us to say that in pregnancy certain toxic substances were retained in the blood, but what these substances were we did not yet know.

The best preventive treatment of puerperal eclampsia was an eliminative treatment—stimulation of the kidneys, intestines, liver, skin, and lungs. By the expectant treatment of a few years ago the mortality was thirty per cent. for the mother and seventy-five per cent. for the child. In the actual curative treatment there were three guiding principles, viz.: (1) The control of the convulsions; (2) the emptying of the uterus; (3) the elimination of the poison. For the first he knew nothing better than chloroform, not continued for more than two hours. Certain women took this badly, and then we must fall back upon chloral. The best treatment was to follow the chloroform with chloral so as to prolong the effect of the chloroform.

He would not resort to morphine until these two agents had been tried. It had been accepted as a clinical fact that in ninety per cent, of the cases when the uterus was immediately emptied the convulsions ceased, and the patient was practically convalescent. In the second stage of labor the emptying of the uterus was comparatively simple, but before confinement it was more grave. The speaker said that he had been taught in Germany that the induction of premature labor was criminal, for the irritation tended to bring on convulsions. Last year, at a discussion at the Academy of Medicine, out of eleven speakers ten were in favor of the immediate emptying of the uterus in cases of eclampsia. In the first stage of labor, the uterus might be emptied in thirty minutes with perfect safety to both mother and child. In the majority of cases the first or second convulsion induced labor and caused the supravaginal portion of the cervix to be drawn upward. When this had occurred, the uterus could ordinarily be emptied in forty minutes. As soon as convulsions occurred in the first stage of labor, he would favor the emptying of the uterus (1) by accouchement forcé, and (2) by deep incision of the cervix. He believed there were some primiparæ who could not be safely delivered by one of these operations alone. In a recent eclamptic case at the Emergency Hospital, after two bougies had been in the uterus twenty-four hours and had failed to induce labor, he chloroformed the patient and performed manual dilatation of the cervix, or accouchement forcé, for twenty minutes. At this point the mother's heart became weak, and, as the cervix was only two thirds dilated, it was incised and the child extracted, and the parturient canal packed with iodoform gauze. Mother and child recovered.

The eliminative treatment should go hand in hand with the controlling of the convulsions and the emptying of the uterus. Catharsis could be excited by croton oil if the patient were comatose, and this could be followed by salines. High injections of solutions of sulphate of magnesium were very valuable here. Nitroglycerin when given hypodermically was very valuable for its action on the heart and kidneys. Strange as it might seem, strychnine had proved very useful when given to combat the shock of the puerperal state. It certainly did not tend to increase the tendency to convulsions, He had not used bloodletting in puerperal eclampsia, although it was doubtless of advantage if the arterial tension were great. His practice was under such circumstances to allow some bleeding to take place in the third stage of labor. It had been well said that the better obstetrician was he who avoided eclampsia by preventive treatment rather than he who would perform a difficult and bloody operation for the relief of this condition. It was quite common for eclampsia to occur in women pregnant out of wedlock. The two cases cited were such. In cases in which the children were large or the pregnancy multiple, there was also greater liability to puerperal eclampsia. Increased metabolism accounted for these latter facts.

Pilocarpine he had used in one case. Pulmonary cedema had almost immediately ensued, and death had occurred in six hours. An autopsy bad revealed advanced kidney disease.

Veratrum viride he only used when the immediate emptying of the uterus, the bleeding encouraged in the third stage, and the chloral hydrate failed to reduce the arterial tension. He avoided its use when possible.

Dr. C. E. Lockwood said that the literature of Bright's disease seemed to be a wilderness of theories and a dearth of facts. A glance at the causes of dropsy or albuminuria showed that the theories advanced seem to refer to an increase of arterial tension. Another theory of albuminuria was that it depended upon the rapidity of the circulation of the kidney. When it fell below a certain point, the oxidation in the epi-

thelial cells was imperfect, and they became permeable to the albumin. Roberts divided cases of puerperal eclampsia into three classes—viz.: (1) Those occurring in Bright's disease; (2) those occurring in primipare, partly uremic and partly reflex where there was passive congestion; and (3) those due to meningeal irritation. In the two latter this writer advised depletion, whereas in the first class he spoke of chloroform but did not advise depletion. The speaker said the suggestions in the paper regarding the circulation, vitiation of the blood, and the sensibility of the nerve centers were well borne out in these theories which had been promulgated.

Dr. Page said that he still held that when we came to treat these convulsions there was no time to eliminate the poison—if we attempted this we might eliminate the patient. The time to adopt eliminative treatment was in the interval, when there was plenty of time for that treatment. Bleeding did not eliminate the poison nor did nitroglycerin, but within five minutes the excited nerve centers and the arterial tension could be relieved by the treatment he had described in his paper, and in this way we could bridge over the difficulty until the more urgent symptoms had subsided.

#### AMERICAN LARYNGOLOGICAL ASSOCIATION.

Fifteenth Annual Congress, held in New York on Monday. Tuesday, and Wednesday, May 22, 23, and 24, 1893.

The President, Dr. Morris J. Asch, of New York, in the Chair.

(Continued from vol. lviii, page 674.)

The Treatment of Deviations of the Nasal Sæptum.— Dr. John O. Roe, of Rochester, read a paper on this subject. (See page 424.)

The President: In order to correct deviations in the nasal septum it is absolutely necessary that the elasticity of the septum be broken down, and this can not be done unless you divide it entirely. In my opinion, there is no other way.

Dr. Mulhall: Dr. Roe's instrument seems to defeat the very purpose for which Dr. Steele's instrument was intended, which was to cut entirely through the sæptum. Unless you cut all the way through, I do not see how you can force the fragments sufficiently far back. It also entails less danger of septic poisoning than by cutting only on one side.

Dr. De Blois: Dr. Leland, of Boston, in correcting these deviations, breaks the saptum partly with his forceps and partly with his fingers, and then inserts a perforated plug of hard rubber. I did it as long as ten years ago in the same way. I inserted an ordinary elliptical tube, with plaster of Paris at the outer end to keep it in place; but, although I did this long before Dr. Leland, I never obtained the universally excellent results that he does.

The President: In a great many of these cases I break down the cartilage with the finger, pushing it through the opening made in the sæptum, and breaking down each segment at its base.

Dr. Wright: I think the success Dr. Roe has obtained in his cases is truly remarkable. I myself must confess that I have met with many dismal failures. I remember only one case that turned out entirely satisfactorily. I have found it difficult to keep the fragments in place. Without cutting entirely through the sæptum, I do not see how its resiliency can be broken down. It always springs back. In one case this winter I made a number of parallel incisions with Dr. Asch's instrument, and then used the finger to push the fragments into a straight line, and inserted a very thick drainage-tube, as large as my little finger, and left it in there, changing it every day. It always gave rise to much pain on removing it. I must confess that I

am extremely doubtful about the theory of keeping the nose aseptic; I do not think it is possible. Of course, Dr. Roe has had extensive experience in this line, and his word carries great weight. He did not state what he did with the redundant portion of the septum. When you push the convex septum back into its normal position, you have some redundant tissue left. It seems to me that this must be crumpled on itself in order to bring the general contour of the septum to a straight line.

Dr. Roe: In correcting these deviations of the nasal sæptum we must remember that no one method of operating will apply in every case. We must adapt the operation to the varying conditions found in each case, and no one instrument will serve the purpose every time. In some instances such instruments as I have shown you are not required. Sometimes the osseous portion of the sæptum is so thin that it can be forced over with the finger or with a smooth spatula, and held there by a retaining dressing. The osseous portions will often remain in place after being held there four or five days. The cartilaginous portion must, however, be freely incised, and, being more resilient, must be held there a much longer time. I have had no trouble with the redundant tissue in these operations. In the osseous portion the bone is simply crushed, while the cartilaginous portion readily adapts itself to its new position. When performing these operations in children I use chloroform, and in adults cocaine; although, if the patient is very nervous, it may be necessary to give a few whiffs of chloroform at the moment of performing the operation.

### Book Notices.

A Text-book of the Theory and Practice of Medicine. By American Teachers. Edited by William Pepper, M. D., Provost and Professor of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania. In Two Volumes. Illustrated. Vol. II. Philadelphia: W. B. Saunders, 1894. Pp. xii-1046.

The volume opens with "general considerations concerning the biology of bacteria, infection, and immunity," and sixty-nine pages are devoted to these subjects. Though advances in this branch of medical science are now so common and so rapid that a theory of to-day is obsolete to-morrow, and therefore it may well be that these "considerations" may soon be of small value as compared with the rest of the work, yet are these no arguments against the introduction of matter which represents the present state of our knowledge upon subjects so important. This present knowledge is put forth by the writers with great force, and, from the practitioner's standpoint, with much completeness. Especially interesting and valuable is the consideration of artificial immunity as produced by inoculation of small (not fatal) quantities of virulent cultures of specific microorganisms, or of attenuated micro-organisms, by the injection of products of these micro-organisms or serum from animals artificially rendered proof against the disease. The chapter is concluded by a necessarily brief but highly suggestive consideration of serum therapy.

Chapters on diathetic diseases, rickets, osteomalacia, obesity, biliary lithiasis, gravel, diabetes mellitus, and polyuria follow.

Rheumatism and gout are next considered, and most ably. A classification of "that extensive group of symptoms which, while dependent upon the same causes with articular rheuma-

tism, are displayed in those organs and tissues that are not connected with the joints themselves," under the heading "abarticular rheumatism," is most logical and satisfactory. In this class are placed the manifestations of the rheumatic poison in the skin, the blood-vessels, the eye, the muscles, and the viscera.

The diseases of the blood come next, and the methods of blood examination are carefully described. The chapters on the blood diseases are among the most valuable in the volume, and present the recent advances in this most important subject. The illustrations are a feature of these chapters and are unusually good.

A hundred and fifty-five pages are given to the diseases of the heart, and, although it was originally the intention of the editor to have them written by an authority other than himself, it is difficult to see how the work could have been more satisfactorily done. After chapters on the blood-vessels, the respiratory passages, and the pleura, are presented the diseases of the lungs.

Examinations of the urine and the diseases of the kidney are next considered. The chapters on kidney diseases present a classification at once so simple and so complete, and a description so perfect, as to rival in excellence, if not to excel, any other portion of the book. A more satisfactory presentation and elucidation of this intricate subject it would be difficult if not impossible to suggest.

The diseases of the stomach and intestines are then described, and then those of the liver.

The discussion of diseases of the pancreas occupies a greater space than is usual in medical text-books, and naturally, since they are affections of more recent investigation. It is, therefore, a matter of congratulation that they are discussed by an authority whose name has long been associated with investigation into their pathology. Their consideration shows great ability and completeness, and, though these affections can not be considered as finally solved, the contribution is exhaustive and complete to the point at present attainable. With this chapter the volume ends.

In our issue of July 8, 1893, we reviewed the first volume of this work and said: "It is undoubtedly one of the best textbooks on the practice of medicine which we possess." A consideration of the second and last volume leads us to modify that verdict and to say that the completed work is, in our opinion, the best of its kind it has ever been our fortune to see. It is complete, thorough, accurate, and clear. It is well written, well arranged, well printed, well illustrated, and well bound. It is a model of what the modern text-book should be.

Lectures and Essays on Fevers and Diphtheria, 1849 to 1879.

By Sir William Jenner, Bart., G. C. B., M. D. Lond., and
F. R. C. P. Oxon., LL. D. Cantab. and Edin., etc. New
York: Macmillan & Co., 1893. Pp. xii-8 to 581. [Price,
84.]

This volume is a fitting exemplar of the careful and scientific work that has placed the author in the foremost rank of his profession. It is to be regretted that the many demands made upon the physician's time at the present day prevent that review of the history of medicine that shows the slow growth of the science, as such, and the obligations that the profession is under to men whose skill has contributed to its advancement.

The volume is a collection of various essays that appeared between 1849 and 1879, and are now published in compliance with the request of many of the author's medical friends. These essays are based on the statistics of personal observation, regarding which the author wrote: "The method I have

April 7, 1894.]

adopted, however prolix it may be, however difficult to conform to, however tedious the details into which it leads, has this advantage, that if the observer be honest and capable of noting what is before him, thinking men may judge of the value of his facts, the force of his reasoning, and the correctness of his conclusions; whereas, general observations, while they are totally incapable of proving anything, are exposed to all the fallacies of definite statements, because the one, like the other, rests ultimately on the accuracy of the facts observed. If the observations on which any reasoning is founded be erroneous, no cloaking of these observations in general terms can render the conclusions correct." It is to be regretted that many authors of the present day do not recognize this fact.

The volume is divided into two parts, one on fevers and one on diphtheria. The former is devoted to typhoid, typhus, and relapsing fevers and to the various phenomena of the acute specific diseases. The second section is composed of two lectures on diphtheria and one on croup. Even in 1861 the author advocated the value of local treatment of diphtheria, though he protested against the too frequent application of powerful solutions. These lectures can not fail to prove interesting to physi-

Atlas of Clinical Medicine. By Byrom Bramwell, M. D., F. R. C. P. Edin., etc. Vol. II. Parts II and III. Edinburgh: T. & A. Constable, 1893. Pp. 45 to 90; 91 to 128.

The second volume of this admirable work is now complete. It has been issued in three fasciculi, each of about forty large folio pages. As in the first volume, the illustrations, which consist of thirty large plates and over twenty woodcuts, are a striking feature of the work. In the opinion of the author they are not, however, the most important feature. Great labor has been expended in the preparation of the text, and upon most subjects it is deserving of the highest commendation-The title is somewhat misleading, for the work is, in fact, a very elaborate illustrated treatise on clinical medicine. The same general plan has been adopted as in the first volume. The outline presented for the clinical investigation of each disease is a peculiar and very important feature. It has been prepared with much care and will prove of the greatest aid to the clinician in the recording of his histories.

The first part is devoted to measles, scrofula, Friedreich's ataxia, and alterations in the fields of vision. The latter subject is considered at great length. Special attention is devoted to the clinical significance and importance of these various alterations. Histories of numerous cases are given and the illustrations are very complete. The second part is devoted to syphilis and Asiatic cholera. Two pages are devoted to a most interesting discussion on anticholeraic inoculation. The system has been tested extensively upon animals, and a period of immunity of at least four months and a half has been obtained. Inoculation is reported in over fifty human subjects. The operation is abundantly proved to be harmless, but its effect in the prevention of cholera has yet to be demonstrated during an epidemic. The author is very sanguine as to the beneficial results to be expected. The third part is devoted chiefly to exophthalmic goître and acromegaly. The latter disease is extremely rare and has passed unrecognized until recently. It receives very careful attention and is profusely illustrated. Goître is treated of in a most satisfactory manner, and the illustrations are especially good. In this very important disease the author believes that there are five great primary symptoms -increased frequency of the heart's action, enlargement of the thyreoid, prominence of the eyeballs, muscular tremor, and general nervousness. All other symptoms are considered as secondary.

On the whole, the second volume fully maintains the high standard attained by the earlier portion of the work.

Essentials of Physics. Arranged in the form of Questions and Answers. Prepared especially for Students of Medicine. By FRED J. BROCKWAY, M. D., Assistant Demonstrator of Anatomy at the College of Physicians and Surgeons, New York. Second Edition, revised. With One Hundred and Fifty-five Illustrations. Philadelphia: W. B. Saunders, 1894. Pp. ix-17 to 330. [Price, \$1.] [Saunders's Question Compends.]

THE author's additions have been of a practical character and are intended to make this edition up to the advances in physics. We know of no manual that affords the medical student a better or more concise exposition of physics, and the book may be commended as a most satisfactory presentation of those essentials that are requisite in a course in medicine.

Syphilis. Its Treatment by Intramuscular Injections of Soluble Mercurial Salts. By Edward Cotterell, F. R. C. S. Eng., etc., Surgeon (Out-Patients), London Lock Hospital, etc. London: John Bale & Sons, 1893. Pp. 36.

THE author of this little brochure is one who has faith in the advantages of the intramuscular injection of mercury. He reviews the various soluble salts of mercury that have been used in this method of treatment. He prefers the sozoiodol of mercury, that was introduced by Schwimmer in 1892, which he administers in a solution containing iodide of sodium, and he states that it produces practically no local reaction. He does not make the injections into the subcutaneous tissue, but into the muscle substance, preferably of the gluteal region, and he recommends the employment of a platino-iridium needle for the hypodermic syringe.

He considers that injections made once a week for six or seven weeks, or until all skin and throat manifestations have disappeared, suffice for preliminary treatment, the injections being subsequently given fortnightly, and then monthly.

The author does not enter into any historical or critical review of this method of treatment, but rather contents himself with a presentation of the results of his own observation.

The Art of Massage. By A. Creighton Hale. Profusely illustrated with Original Drawings. London: The Scientific Press, Limited, 1893. Pp. xvi-144. [Price, 6s.]

THE authoress briefly remarks on the antiquity and uses of massage, describes the qualifications necessary for a masseuse, the structure and functions of the body, the instruments and medicaments necessary for massage, the various manipulative procedures, and then in a number of chapters reviews the structure of a region or member and describes the varieties of massage that are most suitable, the final chapters of the volume being devoted to the treatment of various familiar diseases. Excellent illustrations of and directions for each of the varieties of massage are given. The volume is evidently written by one who is fully conversant with her subject, and it is an excellent manual.

The Blot upon the Brain. Studies in History and Psychology. By WILLIAM W. IRELAND, M. D., Edinburgh, formerly of H. M. Indian Army, etc. Second Edition. New York: G. P. Putnam's Sons, 1893. Pp. viii-388.

The fact that a second edition of this work has been published attests the popularity of the studies of a physician whose historical acquirements are equal to his attainments in psychiatry.

Dr. Ireland presents excellent reasons for believing that Mohammed and Joan of Are were the victims of hallucinations, that Nero, Caligula, and Commodus were paranoiaes, and that many of the Roman emperors were the subjects of neuroses. His criticisms on the royal families of Spain and of Austria show the neurotic taint that accounts for many of their acts.

The author is a believer in the dual functions of the brain. "The intellectual faculties are double," he says, "both sides of the brain working at once, and each side having its impressions simultaneously registered."

The chapters on wordless thought, on folie à deux, and on unconscious cerebration are particularly interesting.

The volume is one that will prove as interesting to the lay as to the professional reader.

Die Beziehungen des Schorgans und seiner Erhrankungen zu den äbrigen Krankheiten des Körpers und seiner Organe. Von Dr. Max KNIES, Professor a. o. an der Universität Freiburg i. B. Zugleich Ergänzungsband für jedes Hand- und Lehrbuch der inneren Medicin und der Augenheilkunde. Mit 21 Figuren im Texte. Wiesbaden: J. F. Bergmann, 1898. Pp. xi-484. [Preis, 9 Mark.]

A WORK on the relation of the visual organs and their diseases to general and organic diseases is one that has as much interest for the general practitioner as for the specialist.

The first section of this work is devoted to the disorders arising from diseases of the nervous system, both functional and organic. The second section refers to the various skin diseases that seem to influence visual disorders. The third section treats of the relation of diseases of the digestive system. The fourth relates to that of diseases of the respiratory organs; the fifth, to that of the organs of circulation; the sixth, to that of the kidneys; the seventh, to that of the sexual organs; the eighth, to that of poisons and of the infectious diseases; and the ninth, to that of constitutional anomalies, such as anemia, chlorosis, leucæmia, diabetes, rhachitis, exophthalmic goitre, and Addison's disease, etc.

The different topics are well considered, and the work deserves a wide popularity.

The Child Physically and Mentally. Advice of a Mother according to the Teaching and Experience of Hygienic Science. Guide for Mothers and Educators. By Bertha Meyer, author of From the Cradle to the School, and other works. Translated by Friederike Salomon. Revised by A. R. Aldrich. New York: M. L. Holbrook Co., 1893. Pp. x-155.

This is a useful book for any mother desirous of sound, practical advice regarding the physical and mental training of her child during its early years. The authoress is a disciple of Fröbel, and her book is based on the principles of his teaching.

We notice an error on page 23 in the statement that Lady Montagu had her children vaccinated from the real cow-pox; they were, as a fact, inoculated with small-pox.

Handbook of Public Health and Demography. By Edward F. Willoughby, M. D. Lond. London and New York: Macmillan & Co., 1893. Pp. xvi-509. [Price, \$1.50.]

The success that the author's Principles of Hygiene, originally published in 1884, attained has induced him to rewrite that work, making the additions necessary to change it from a semitechnical into a technical one.

One of the characteristics of the volume, to which the author refers in his preface, is the stress he places on the princi-

ples involved and the laws implied in each topic that is discussed.

The first section of the volume is devoted to dietetics, and includes an exposition of the doctrines and the latest conclusions of the Munich school, a concise statement of the changes in food stuffs produced by the various methods of cooking, and a brief review of some of the adulterations of food.

The sections on clothing, habits, exercise, and rest have been well considered.

The directions given for the examination of air and of water seem to be too meager for a work of this character; and the same criticism might be made regarding the methods to be employed for disinfection. Quarantine and municipal sanitation, as generic entities, are not mentioned.

What is given in the work is excellent, the author's style is pleasing and clear, and, aside from the small type that is trying to the eyes, the volume is to be commended.

The Treatment of Constitutional Syphilis. By Oswald Ziemssen, M. D., Wiesbaden. London: H. K. Lewis, 1893.

As the author very truly states in the preliminary portion of this little volume, the question of how constitutional syphilis can best be treated must be regarded as still open. He would amend Kaposi's statement that syphilis is "the most easily curable of all infectious constitutional diseases" by the simpler phrase "syphilis is not incurable"; or, in other words, and as a fundamental proposition in syphilology, "the radical cure of constitutional syphilis is possible, but there is as yet no certain proof of this at our disposal, relapses having occurred even after many years."

Dr. Zemssen objects to the contention that syphilis has been cured by the excision of the site of infection, because occasionally constitutional syphilis has been met with in cases where there has been no hard sore; so the fact that constitutional symptoms did not follow excision of a local lesion proves nothing. And yet, while calling attention to this element of uncertainty that is within the experience of every syphilologist, he urges the adoption of specific treatment as early as possible, because such treatment can do no harm, and it affords, at least, the moral satisfaction that nothing has been left undone.

The author rapidly reviews the expectant method of treatment, the diaphoretic and diuretic method, and the treatment by baths.

His treatment is with mercury; he says: "The longer and more energetically such treatment is carried out, the greater is the prospect of the patient being definitively cured." The various methods of administering mercury are reviewed, and the author prefers the inunction method with thermal treatment. Of course, for later symptoms the iodides are employed.

This little volume is an interesting résumé of the subject of the treatment of syphilis, rather confirming what is known than adding to our knowledge.

### BOOKS, ETC., RECEIVED.

The Dispensatory of the United States of America. By Dr. George B. Wood and Dr. Franklin Bache. Seventeenth Edition. Thoroughly revised and largely rewritten. With Illustrations. By H. C. Wood, M. D., LL. D., Professor of Materia Medica, etc., in the University of Pennsylvania, etc.; Joseph P. Remington, Ph. M., F. C. S., Professor of Theory and Practice of Pharmacy in the Philadelphia College of Pharmacy, etc., and Samuel P. Sadler, Ph. D., F. C. S., Professor of Chemistry in the Philadelphia College of Pharmacy. Philadelphia: J. B. Lippincott Company, 1894. Pp. xliv-1930.

An American Text-book of the Diseases of Children. In-

cluding special chapters on Essential Surgical Subjects; Diseases of the Eye, Ear, Nose, and Throat; Diseases of the Skin; and on the Diet, Hygiene, and General Management of Children. By American Teachers. Edited by Louis Starr, M. D., Physician to the Children's Hospital, etc., Philadelphia. Assisted by Thompson S. Westcott, M. D., Attending Physician to the Dispensary for Diseases of Children, Hospital of the University of Pennsylvania. Philadelphia: W. B. Saunders, 1894. Pp. xiv-1190. [Price, \$7.]

Essentials of Physics. Arranged in the form of Questions and Answers. Prepared especially for Students of Medicine. By Fred J. Brockway, M. D., Assistant Demonstrator of Anatomy at the College of Physicians and Surgeons, New York. Second Edition, revised. With One Hundred and Fifty-five Illustrations. Philadelphia: W. B. Saunders, 1894. Pp. ix-17 to 330. [Price, \$1.] [Saunders's Question Compends.]

Syllabus of the Obstetrical Lectures in the Medical Department of the University of Pennsylvania. By Richard C. Norris, A. M., M. D., Demonstrator of Obstetrics, University of Pennsylvania, etc. Third Edition. Philadelphia: W. B. Saunders, 1894. Pp. xviii-222. [Price, §2.]

Congenital Affections of the Heart. By George Carpenter, M. D., London. Member of the Royal College of Physicians, etc. London: John Bale & Sons, 1894. Pp. 103. [Price, 3s.

The Discovery of Modern Anæsthesia. By Whom was it Made? A Brief Statement of Facts. By Dr. Laird W. Nevius, Specialist in the Administration of Nitrous Oxide Gas for Minor Surgery, etc. New York, 1894. Pp. 100.

Transactions of the American Pediatric Society. Fifth Session. Held at West Point, N. Y., May 24, 25, and 26, 1893. Volume V.

Twenty-fourth Annual Report of the Massachusetts Homeopathic Hospital, Boston, and the Ladies' Aid Association, for the Year ending December 31, 1893.

### New Inventions, etc.

A KNIFE AND SOUND FOR ANTERIOR VAGINAL FIXATION.

By HIRAM N. VINEBERG, M. D. The surgical treatment of backward displacements of the uterus has engaged the profession for the past years. Many have been the operations ingeniously devised for the relief of

this very common affection. Some have stood the test of time, the majority have been buried in oblivion. Still, so unsatisfactory is the treatment in general by mechanical means that the most conservative men nowadays resort to some one or other surgical procedure to fix the displaced uterus forward. Even so ultra-conservative a man as Fritsch has been compelled to resort to ventro-fixation fifteen times in one year in his hospital practice. This operator is still a firm believer in the use of pessaries, but he tells us he was forced to adopt the more radical measure from his unsatisfactory experience in treating the working and middle classes with mechanical supports. When the abdomen has to be opened for some other lesion, the consensus of opinion at the present time is in favor of ventrofixation; but when the backward displacement is not complicated by diseased annexa, as is often the case, a less serious operation is in place. Of these the one that seems to have the most promise in it, and is attended with the least objections, is anterior vaginal fixation, or Mackenrodt's operation. I believe I was among the first in this country to perform the operation successfully. I have now done the operation nine times, and will say here incidentally that in properly selected

A Primer of Psychology and Mental Disease. By C. B. cases it is the operation pur excellence. At my first operation Burr, M.D., Medical Superintendent of the Eastern Michigan I happened to have with me an ordinary staphylorrhaphy knife, which seemed to answer the purpose of making the longitudinal incision and separating the vaginal flaps better than any other scalpel I had in my possession. Its only objection was its small size. I had, therefore, W. F. Ford & Co. construct for me a larger knife after the same pattern, which I have since been using with a great deal of satisfaction. The convexity of the blade is useful in entering nicely into the concavity existing in the anterior vaginal wall, even when this is put on the greatest stretch by two volsellæ, one caught in the Cases. By W. L. Burrage, A. M., M. D., Boston, Mass. [Re- cervix, the other in the urethral mound. This form of the blade is also useful in making the sharp dissections of either

The Cause and Cure of Malignancy. An Important An- | vaginal flap from the underlying bladder, and the handle, being nouncement to the Medical Profession. By William Thornton, of smooth metal and quite thin, comes into good service in making the blunt dissections in this step of the operation and also in the next step of bluntly dissecting the bladder from the cervix and uterus.

> At my first operation I used the largest uterine sound I could obtain in the city to bring the uterus forward. Although the case was the easiest I have met with, I had great difficulty in keeping the uterus anteverted with the sound, as it was too flexible and too short, and the handle was too small to enable me to catch a good hold on it. I had therefore this sound constructed. As will be seen, it is much longer than the ordinary uterine sound, is very much heavier, has a good-sized handle which can be firmly grasped, and has a large knob at its end, so as to avoid the danger of penetrating the uterine wall, which a sound without a knob might do. In fact, an operator in this city, in using an ordinary steel bougie to antevert the uterus, did penetrate the uterus and open into the peritoneal cavity, and was compelled to open the abdomen. The sound is made of copper wire and is consequently slightly flexible. It measures from tip to shank twenty-five centimetres, and to the end of the handle thirty-five centimetres. The circumference of the knob is twenty-two millimetres, and two inches and a half below this point the circumference is seventeen millimetres and a half. It is curved at its upper end to correspond to the direction of the anteverted uterus, and the curve at the lower end is to allow the handle to be brought farther back than it would if it were

> I have used this sound in the last six operations and have found it exceedingly satisfactory, as it facilitates the execution of the operation.

127 East Sixty-first Street, March 13, 1894.

### Miscellany.

The Association of Military Surgeons of the United States will hold its fourth annual meeting in Washington, on May 1st, 2d, and 3d, under the presidency of Dr. Nicholas Senn, of Chicago, surgeon general of the National Guard of the

State of Illinois. Besides the president's address, entitled Abdominal Surgery on the Battlefield, the preliminary programme includes the following papers on The Transportation of the Sick and Wounded: History, by Colonel C. H. Alden, Assistant Surgeon General, U.S.A., Washington; Litter, by Major Valery Havard, Surgeon, U. S. A., Fort D. A. Russell, Wyoming; Travois, by Major John Van R. Hoff, Surgeon, U. S. A., Governor's Island, New York; Railway, by Colonel Louis W. Read, Surgeon General, N. G., Pa., Norristown, Pa.; On Board Ship, by Dr. Albert L. Gihon, Medical Director, U.S.N., Washington; and Ambulance, by First Lieutenant Myles Standish, Surgeon, Mass. V. M., Boston; also miscellaneous papers as follows: Notes on the Introduction of Tent Field Hospitals in War, showing the Advantages of Treating Military Invalids under Canvas on the Battlefield, instead of Buildings improvised for Hospitals, by Colonel B. J. D. Irwin, Assistant Surgeon General, U. S. A., Chicago; The Medical Officer at the Summer Encampments, by Lieutenant-Colonel C. R. Greenleaf, Deputy Surgeon General, U. S. A., San Francisco; Easy Methods of Carrying out the Principles of Aseptic Surgery, by Colonel R. Reyburn, Late Surgeon and Brevet Lieutenant Colonel, U. S. Vols., Washington; Equipment and Instruction of Sanitary Soldiers, by Captain C. F. Mason, Assistant Surgeon, U. S. A., Fort Snelling, Minnesota; A Field Kitchen Wagon for Cooking Food and Sterilizing Dressings at Dressing Statious and on the March, by Captain H. O. Perley, Assistant Surgeon, U. S. A., Plattsburg Barracks, New York; The Personal Equipment of the Sanitary Soldier, by First Lieutenant G. D. DeShon, Assistant Surgeon, U. S. A., Fort D. A. Russell, Wyoming; The Action of Rattlesnake Venom upon the Bactericidal Power of the Blood Serum, by Captain Charles B. Ewing, Assistant Surgeon, U. S. A., Fort McHenry, Maryland; The Relation of the National Guard Surgeon to the Medical Profession and to the Community, by Captain T. C. Clark, Assistant Surgeon, N. G. of Minnesota, Stillwater, Minn.; Saber Wounds, by Colonel R. E. Giffen, Surgeon General, N. G., Neb., Lincoln, Neb.; The Special Training of the Medical Officer, with Brief Notes of the Courses of Instruction at Army Schools Abroad and at Home, by Colonel C. H. Alden, Assistant Surgeon General, U. S. A., Washington; A New Sanitary Appliance in the First Line of Battlefield Assistance, by Major John Van R. Hoff, Surgeon, U. S. A., Governor's Island, New York; Some Notes on the Late Civil War, by Colonel Richard F. Michel, Surgeon General, Alabama State Troops, Montgomery, Ala.; Destructive Effects of the Krag-Jorgensen Rifle Projectile at the Actual Ranges, by Captain Louis A. La Garde, Assistant Surgeon, U. S. A., Denver, Col.; Camp Hospitals, by Major Lawrence C. Carr, Surgeon, N. G. Ohio, Cincinnati; Progress of Medico-Military Science in the National Guard of New Jersey, by Brigadier-General J. D. McGill, Surgeon General, N. G. of New Jersey, Jersey City; The Remote Effects of Gunshot Wounds of the Extremities, by Lieutenant-Colonel C. M. Woodward, ex-Surgeon General, Michigan State Troops, Tecumseh, Mich.; Notes on the Transportation of Sick and Wounded, by Captain J. D. Glennan, Assistant Surgeon, U. S. A Case of Post-mortem Perforation of the Stomach.—
The March number of the Archives de médecine et de pharmacie

militaires contains an article by M. Leymarie in which he remarks that post-mortem perforation of the stomach is a rare thing in pathological anatomy. The causes of this self-digestion of the walls of the stomach still remain a mystery, he says, and if, as in the cases observed by Professor Brouardel, a superabundant secretion of the gastric juices following the ingestion of strychnine may be cited, there are others where the cause of the perforation is not known. In a case described by Dr. Vibert before the Société de médecine légale the diaphragm itself was perforated and the contents of the stomach were discharged into the left pleura. M. Leymarie had observed a case of post-mortem perforation of the stomach at the Military Hospital at Dey, in the service of M. Peyret. The patient was a young man who had been wounded in a street fight, and died forty-eight hours after the accident. There was a flow of serum from the left ear, and a slight paralysis of the left side of the face confirmed the diagnosis of fracture of the base of the skull. The gravity of the lesions ascertained at the autopsy was a surprise. The body was that of a young and vigorous man and showed no signs of putrefaction, but the sero-sanguineous flow still continued from the ear. An exami nation of the skull revealed the following lesions: A large clot extending over the base of the dura and elevating the cerebral substance; attrition of the cortical zone of the posterior part of the left lobe, and smaller lesions of the right lobe. On raising the dura a large fracture was discovered; beginning at the left foramen rotundum, the tract of the fracture extended along the anterior border of the petrous portion of the temporal bone, crossed this bone perpendicularly to its axis, and traveled obliquely the whole extent of the occipital in the direction of the internal occipital protuberance, before which it deviated slightly and involved the superior angle of the left parietal. In the thoracic cavity nothing was noticed about the heart or the right lung, but the left lung showed a brownish spot on its diaphragmatic face. Apparently there was nothing abnormal in the abdominal cavity, and there was no peritonitis, but after the small intestine had been carefully depressed and the transverse colon slightly raised, a loss of substance as large as one's hand was discovered on the lower side of the diaphragm, on the left, involving the whole thickness of the muscle except the superior aponeurosis, the dull color of which had already been noticed on opening the thorax. The diaphragmatic muscular tissue had disappeared, and there remained only fibrous fasciouli resembling tow, which covered the bottom of the ulcer. At this level the large cul-de-sac of the stomach showed a perforation nearly ten centimetres in diameter; it was irregular and extended nearly to the cardia, and the edges were rather cleancut. At certain points a very narrow greenish border could be seen. The walls of the stomach were in good condition, and there was no trace of alteration of the mucosa or of ulceration. The cavity was empty. The posterior cavity of the omentum contained a teaspoonful of a brownish liquid, but the signs of digestion, nearly finished, of the diaphragm and the absorption of the lungs showed that the quantity of liquid discharged must have been great.

The Vagabonds' Disease.—A correspondent of the Journal des praticiens gives an account of a recent clinical lecture given in Algiers by Dr. Raynaud on the subject of the diagnosis of the condition called by the English the "vagabonds' disease," a morbid condition that has only rarely been described, he says, in spite of its comparative frequency. It is a cachexia accompanied with pigmentation of the mucous membranes, pigmentation of the skin, and prurigo due to lousiness. The case on which M. Raynaud lectured was that of a person who had rebellious diarrhœa and was in a state of extreme

cachectic misery. The skin of his loins, his buttocks, and his abdomen was bronzed and melanodermic. There was a brownish-yellow pigmentation of the lips, of the cheeks, and of the palate, with prurigo. Traces of phtheiriasis were found.

What diagnosis was to be made under such circumstances? To settle this question, M. Raynaud thought the best course to pursue was to raise and discuss the following hypotheses: The absence of malarial antecedents and signs put aside the idea of malarial melanodermia, also that of pigmentation caused by the use of nitrate of silver. Moreover, no one would suppose that the case was one of Addison's disease. This disease, however, was the affection from which the one under consideration had to be distinguished. The two resembled each other in the tegumentary pigmentation and in the cachectic condition. It was true that in Addison's disease, pigmentation was most pronounced on the parts that were usually uncovered, such as the neck, the hands, and the face, or were normally pigmented, such as the axillæ, the groins, and the scrotum. The melanodermia of vagabonds' disease was situated on those parts where there had been itching and scratching-the back, the hypochondrium, and the abdomen. It was quite exceptional for it to be found on the mucous membranes. In the long run, it was wise to rest the diagnosis on the localization of this pigmentation in cases where the phenomena of cachexia and asthenia were of a nature to give rise to doubt. In this abnormal cutaneous pigmentation the lecturer saw not only an effect of scratching and of lousiness, but that of poisons carried in the blood and irritating the nerves presiding over the function of pigmentation. Vagabonds' disease, therefore, he concluded, was a skin disease of tropho-neurotic origin; hence its clinical difference from Addison's disease. It was to be treated, and almost always successfully, by means of baths and a tonic regi-

Appendicitis Obliterans.—In the Journal of the American Medical Association for March 24th Dr. N. Senn, of Chicago, publishes an article on this subject and gives the following conclusions:

- Appendicitis obliterans is a comparatively frequent form of relapsing inflammation of the appendix vermiformis.
- 2. It is characterized by progressive obliteration of the lumen of the appendix, by the gradual disappearance of the epithelial lining and glandular tissue, and the production of granulation tissue from the submucous connective tissue which by transformation into connective tissue and cicatricial contraction starves out remnants of glandular tissue, and finally results in obliteration.
- The obliterating process manifests a progressive tendency, and may finally result in complete destruction of all glandular tissue and obliteration of the entire lumen.
- 4. The incipient pathologic changes occur either in the mucous membrane of the appendix, in the form of superficial ulceration, or as an interstitial process following lymphatic infection.
- 5. The most constant symptoms which attend this form of appendicitis are relapsing acute exacerbations of short duration, moderate or no appreciable swelling at the seat of disease, and persistence of soreness and tenderness in the region of the appendix during the intermissions.
- The process of obliteration may begin at the distal or proximal end, or at any place between, or it may commence simultaneously, or in succession at different points.
- 7. Obliteration on the proximal side gives rise to retention of septic material which finds an outlet through the lymphatics, giving rise to non-suppurative lymphangitis and lymphadenitis.
  - 8. Circumscribed plastic peritonitis is an almost constant

- concomitant of appendicitis obliterans and hastens the process of obliteration.
- 9. Complete obliteration of the lumen of the appendix results in a spontaneous and permanent cure.
- 10. In view of the prolonged suffering incident to a spontaneous cure by progressive obliteration and the possible dangers attending it, a radical operation is indicated and should be resorted to as soon as a positive diagnosis can be made.

The Association of the Alumni of St. Mary's Hospital, Brooklyn.—The annual meeting will be held at the rooms of the Medical Society of the County of Kings, No. 356 Bridge Street, on April 16th, at 2.30 p. m. All the members of the profession are cordially invited to be present. The following papers are announced: Pelvic Abscess and its Treatment, by Dr. A. H. Buckmaster, of New York; Sources of Error in Vital Statistics, by Dr. George E. West; Cystitis from a Surgical Standpoint, by Dr. L. E. Tieste; and The Therapeutics of Digitalis in the Pneumonia of Children, by Dr. Frank De la Vergne. The annual dinner will be held at the Union League Club in the evening.

The New York Academy of Medicine.—The programme for the last general meeting, on Thursday evening, the 5th inst., included the following papers: Appendicitis, strictly a Surgical Disease, by Dr. John A. Wyeth; and The Use of Narcotics in the Treatment of Epilepsy, with Special Reference to the Use of Opium, by Dr. Joseph Collins.

At the next meeting of the Section in General Surgery, on Monday evening, the 9th inst., Dr. John B. Walker will read a paper on Rupture of the Quadriceps Extensor Muscle and its Tendon; an Analysis of 252 Cases, with reference to Treatment and Results; and the discussion on sterilization will be continued.

At the next meeting of the Section in Genito-urinary Surgery, on Tuesday evening, the 10th inst., Dr. George H. Fox will read a paper entitled Some Common Mistakes in the Treatment of Syphilis.

At the next meeting of the Section in Pædiatrics, on Thursday evening, the 12th inst., the subject of cerebro-spinal meningitis will be discussed.

At the next meeting of the Section in Neurology, on Friday evening, the 13th inst., papers are to be read as follows: Haig's Theory of Uric Acid, by Dr. Mary P. Jacobi; Perforating Necrosis of the Spinal Cord, by Dr. Ira Van Gieson; and The Significance of the Ankle Clonus and Exaggerated Knee-jerk, and their Relation to Diagnosis, by Dr. Græme M. Hammond.

The Philadelphia Pathological Society.—The semi-annual conversational meeting will be held in the upper hall of the College of Physicians building, Thirteenth and Locust Streets, on Thursday, April 26th, at 8 P. M. Dr. Simon Flexner, associate in pathology in the Johns Hopkins University Medical School, will deliver an address entitled An Experimental Study of the Nature and Action of Certain So-called Toxalbumins. Members of the medical profession are cordially invited to be present.

The Mutter Lectures.—Dr. Guy Hinsdale, the curator of the College of Physicians of Philadelphia, asks us to announce that the next course, on Some Point or Points connected with Surgical Pathology, will be given in the winter of 1896-97. The lecturer's compensation will be \$600, and the appointment is open to the profession at large. Applications, stating the subjects of the proposed lectures, must be made before July 1, 1894, to Dr. William Hunt, Southeast Corner of Thirteenth and Locust Streets, Philadelphia.

### ELEOMYENCHYSIS.

OR THE TREATMENT OF CHRONIC LOCAL SPASM BY THE INJECTION AND CONGELATION OF OILS IN THE AFFECTED MUSCLES.

HISTORY OF A CASE OF

CLONIC SPASM OF THE SPLENIUS MUSCLE TREATED SUCCESSFULLY IN THIS WAY.

By J. LEONARD CORNING, A. M., M. D.

ONE of the most thankless tasks which confront the neurologists is the treatment of spasm, whether due to purely local causes, as in the various convulsive affections involving the muscles of the neck, or to central lesions, as exemplified by the contractures consecutive to hemiplegia.

To enumerate all that has been attempted for the relief of these conditions could serve no useful purpose, since the exhibit would only impress one with the chaotic state of this branch of neurotherapy. I shall summarize matters, then, by stating that most sedative and stimulating drugs have been exhibited internally in all possible doses, while locally incision, acupuncture, electricity, and counter-irritation have alternately played the principal part. Not much of a practical kind has come of all this polytherapy, and still less has been gained by interminable discussion as to whether this or that particular spasm is to be ascribed to central or purely peripheral causes.

The realization of this came to me many years ago, and I can not, even now, forbear a smile as I recall the many grotesque attempts to relieve convulsive conditions of the muscles of which at various times I have been a witness.

With this experience has come the conviction that if we are to deal effectively with these local spasms we must begin with the muscle itself, addressing our efforts as far as possible to diminishing the morbid irritability of the contractile substance, on the one hand, and to directly impeding the action of the organ on the other. From the consideration of a variety of phenomena, some of which seemed at first quite irrelevant, it one day dawned upon me that these two ends—i. e., diminution of the irritability of the contractile substance and fixation or partial fixation of the organ in a condition of extension might be attained by the injection into the muscle and subsequent congelation there—by the aid of cold—of a bland oil, the solidification point of which should be three or four degrees above the normal blood temperature.

In the first place, I knew not only theoretically but inductively, from experiments on myself and others, that a non-irritating oil might be injected in a melted (fluid) condition into the living tissues, congealed there, and allowed to remain as a solid or semi-solid foreign body for an indefinite length of time without provoking the least inflammatory reaction. With this elementary fact I was able to bring into juxtaposition the apparently quite unrelated but well-established phenomenon that the vigor of muscular action may be sensibly diminished by curtailing the blood-

supply to the organ. As these two facts surged to and fro in my mind, bound by some illusive co-ordination, their true connection dawned one day suddenly upon me. Then, as I now recall the circumstance, I said to myself: "To be sure, I will inject melted oil into a spastic muscle at the first opportunity in sufficient quantity to interfere materially with the blood-flow and metabolism in the organ, and then solidify it (the oil) there by the aid of cold. In this way, in addition to interfering with the nutrition of the organ. I shall be able to directly curtail (mechanically) its action; for the hardened oil can not fail to act as a species of intramuscular splint." Though 'I had occasion over two years ago to make a successful test of this method in a small way in connection with spasm of the muscles of the thumb. only recently have I enjoyed the opportunity of employing it on a large scale. For this privilege I am indebted to Dr. Mortimer Lampson, of Jersey City.

During the latter part of March I was summoned in consultation by Dr. Lampson to give an opinion in the case of a young man who, for the past four months, had suffered continuously from clonic spasm, which was confined to the muscular region of the neck. Within the first fifteen minutes subsequent to my arrival at the bedside the patient had four violent convulsive attacks, accompanied by severe pain; and, availing myself of the opportunity thus afforded to make a thorough inspection, I was able to locate the spasm in the left splenius muscle. While the seizure was at its height the head was drawn violently backward and toward the left (affected) side, the chin remaining somewhat depressed and inclined toward the side of the spasm. Meanwhile the characteristic hard ridge could be telt which marked the protrusion of the rigid splenius beyond the border of the trapezius.

Simultaneously with the advent of the spasm, the patient would seize his head with both hands, and, mustering all his strength, endeavor to control the violent jerking of the head; but the effort was not always successful. As may readily be imagined, clonic spasms of such violence and frequency, lasting several months, and accompanied by severe pain, must have caused nervous and nutritive derangements of a profound character.

Appreciating the gravity of the situation, Dr. Lampson had made faithful trial of all the remedies, both local and general, commonly employed in such cases, but had been unable to modify the frequency or intensity of the spasm. Indeed, the only respite from suffering was had through the instrumentality of opiates.

Confronted by this serious state of affairs, I proposed that we should make a final effort to relieve the patient before invoking the assistance of surgery.

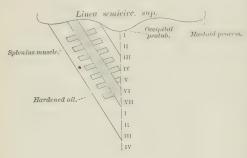

Dr. Lampson consenting, I proceeded to treat the affected muscle in the following manner:

Having procured a suitable oil, the point of solidification of which was somewhat higher than that of the blood temperature, I reduced it (the oil) to a fluid condition by heating over a water bath.

The oil of theobroma mixed with paraffin was found to yield a non-irritating and otherwise suitable product. The melting point was accurately determined by the gradual addition of paraffin in the presence of the thermometer. By the aid of a large syringe armed with a stout hollow needle, I injected eight hundred minims of the melted oil into the center of the muscle, in such a way that it (the oil) was distributed parallel

with the longitudinal axis of the muscle. The fluid oil was then promptly reduced to a solid state by the aid of the ether spray, and subsequently by the application of a small ice-bag over the muscle. The fact that the oil remains solid at the blood temperature will prevent its deportation by the general circulation after the removal of the ice-bag.

In this way a retinaculum or intramuscular splint of hardened fat was formed, extending almost the entire length of the muscle. Some hours subsequently, there being no inflammatory reaction whatever, supplementary injections were made in such a way as to form "ribs" or fatty segments extending across the muscle at right angles to the longitudinal splint of hardened fat, if I may so express it. The oil was then precipitated as before, by the external application of cold to the muscle. The disposition of the fat in the muscle is approximately shown in the subjoined diagram.

Though I confidently expected that good would come from this plan of treatment within a reasonable length of time, I was not prepared for the exceeding promptness of the relief afforded. Indeed, to my surprise, the clonic spasms ceased immediately after the conclusion of the operation; and, in their stead, there remained nothing more than a certain degree of morbid tonicity of the muscle. During the last few days this stiffness has been decidedly less pronounced, so that the tendency of the head to be drawn in the direction of the affected muscle is insignificant and entirely absent at times.

In view of the striking results so speedily accomplished, I can not restrain the conviction that eventually, with the more complete development of atrophic changes in the muscle due to the presence of the oil, the relaxation of the organ may be thoroughly accomplished. As matters stand at present, there is absence of pain; the head is maintained in a normal position; the patient can sleep on the affected side without discomfort, which he has been unable to do heretofore; his appetite has increased notably, and his general bodily condition is improved.

Let me add a word of advice in regard to the best manner of making the injections. In the first place they should be made while the muscle is extended as much as possible, so that the fat deposited may interfere most effectually with the contraction of the organ. To accomplish this, I should not hesitate to etherize the patient; but this is unnecessary in the case of clonic convulsions, and February 1, 1894.

probably urgently demanded only where we are confronted with severe tonic spasm. A second important point is to distribute the oil with regularity throughout the affected muscle, beginning at the origin and continuing the injections till one or more zones of considerable thickness extend to the insertion of the muscle. Moderate massage of the injected parts will greatly facilitate this part of the operation.

The transverse injections may then be undertaken in the manner previously set forth.

Let me also observe parenthetically that it is necessary to employ a hypodermic needle of large size provided with an ample lumen, as the hot and heavy oil is liable to congeal in the small needles conventionally employed for purposes of hypodermic medication. The syringe, too, should be of at least two hundred minims capacity; must be heated to 110° F. before filling; and, with its needle attached, should be kept in hot water of a like temperature till the very moment of making the first injection. Should the oil, in spite of these precautions, congeal in the needle, dipping the latter in hot water will at once clear the lumen.

Finally, it is well not to attempt to accomplish too much at one sitting, but to rely upon supplementary injections undertaken at intervals of three or four days. It must not be forgotten, however, that, in order to obtain success, a large quantity of oil must ultimately be injected. Should there be some local soreness after the operation, the icebag may be allowed to remain in place over the muscle for a few hours. As a rule, however, it should be replaced as soon as possible by a bag of moderately warm water, which often proves most comforting, and tends to cause relaxation of the organ. In this connection, I would remark, as a matter of collateral interest, that I once completely arrested the growth of a small tumor which was pressing upon the supraorbital nerve, and giving rise to considerable pain, by injecting oil into and in the vicinity of the neoplasm, and congealing it permanently by cold, as previously described. The relief from pain was likewise permanent.

To those who have been impressed not only by our inadequate knowledge of the mechanism of spasm, but also by the utter unreliability of the means hitherto proposed for dealing with it, the foregoing observations will, I trust, prove not without interest.

53 West Thirty-eighth Street.

### THE PREVENTION OF DISEASE:

A PROBLEM FOR ALL PHYSICIANS.\*

By WILLIAM WARREN POTTER, M. D., BUFFALO, N. Y.

INTRODUCTION.

The highest office of the physician of modern times is and ever must be in the exercise of his functions toward the prevention of disease. This is neither new nor original, but is nevertheless as true as when it was first uttered in reference to modern physicians and modern medicine.

<sup>\*</sup> Read by invitation before the New York Academy of Medicine, February 1, 1894.

In a medical society meeting it is far more entertaining and even fascinating to describe a brilliant clinical success, either in surgery or medicine, than it is to discourse upon the methods of prevention as applied to the maladies of mankind. But it would be unseemly to address this academy in general session assembled—composed as it is of men who are distinguished in all the specialties of their art—upon any one branch thereof, expecting to attract either the ear or the thought of anything like a considerable number, to say nothing of a majority. But every one is or ought to be interested in the prevention of disease. Moreover, the time has fully come for the discussion, in all medical societies by all medical men, of the manifold questions relating to preventive medicine.

The problems that are involved in this department of medicine must interest the general practitioner whether of medicine or surgery; likewise all specialists in the several departments and branches of medical science and art; nor can the laboratory teacher, whether he be chemist, pathologist, physiologist, or bacteriologist, escape the necessity of a knowledge of how to prevent the diseases whose infection and contagion he is absorbed in studying and analyzing. What man is there who bears the honorable title of "Doctor of Medicine," no matter what his specialty in teaching or practice, who escapes the sometimes intelligent and always persistent interrogations of his patients or friends with reference to the best methods of preventing the spread of cholera, small-pox, diphtheria, typhoid fever, and the like ? He must be prepared to offer an intelligent opinion on all such questions, as well as on those pertaining to plumbing, sewerage, drainage, ventilation, and every detail of house sanitation. Ignorance on, or indifferent acquaintance with, these subjects is a confession of unfitness to retain the title. Happily, however, some of the exanthematous fevers have not now the same dread to humanity as formerly, since the triumph in medicine in solving the methods of their prevention and cure. But if this be true in a certain degree, there is being added to the list a number of maladies that formerly were not thought to be contagious, or at least infectious, but have now become well known to be so through the investigations and studies of clinicians and men experienced in the science of bacteriology.

Permit me to illustrate by accentuating the importance of a better knowledge concerning the prevention of the propagation of a few of the more serious diseases of this class

### THE PREVENTION OF CONSUMPTION.

I may refer first to one disease—namely, consumption—that comparatively lately has become known to the profession as an infectious disorder; a malady that is destroying more inhabitants of the globe than almost any other known disease, and that last year proved fatal to more than six thousand residents of your own city.\*

While it is true that much has been done of late to control its spread and to abridge its ravages in localities,

yet how many physicians are ready to admit even now that it is an infectious malady, and that it may be conveyed to a healthy person who is habitually in the atmosphere of a consumptive? If it were possible to apply the knowledge which a few of the more advanced-a small minority-of our profession now possess with reference to the propagation of consumption and to disseminate this knowledge among the mass of physicians, it would be serving humanity in the highest possible way to concentrate the efforts of the entire force toward preventing the spread of this direful disease. In order to do this effectively it would become necessary at the outset to establish an absolute inspection of all foods of an animal nature as well as supervision of the care of all animals that furnish food for mankind, with a view to a rigid condemnation and destruction of such as prove unfit.

Again, if we should undertake to prevent the spread of consumption by the application of all the intelligent means at our command, it would further involve imperious supervision over the food that our cows eat and their stable care, as well as a like supervision over the animals that are slaughtered for our daily consumption. It further also would involve the inspection by a competent veterinary surgeon of all cows that afford milk supply to our cities and villages and of all the animals that are slaughtered for purposes of food, to the end that every tuberculous beast shall be killed and its body cremated. I consider it essential that the latter order shall be enforced with great exactitude. If any portion of a tuberculous animal, excepting its hide, horns, and hoofs, be permitted to enter the avenues of commerce there is danger of the propagation of disease, and I know of no way to effectively abolish such danger excepting to imperiously insist upon the incineration of all tuberculous carcasses.

But we must not stop here: our food supervision must extend to all domestic birds, fowls, and animals whose milk or flesh we use for food. The quantities of tuberculous food consumed by the people assuredly are enormous, and it will require the most rigid system of inspection and supervision by most skilled, honest, and well-paid officials to interrupt, cut short, or prevent traffic in these dangerous and unwholesome aliments.

Besides this the circumspection and control of railway and steamboat travel as well as hotel life would become necessary, and this would simply arouse an opposition from every traffic official and landlord in the country, to say nothing of the indignation of travelers themselves. Yet none such would complain at the exercise of an absolute authority with reference to restraining the transit of small-pox patients, or those affected with diphtheria or cholera. Nevertheless, these maladies, one and all, have not at present one scintilla of the importance connected with their destructive powers that has consumption.

Another most important step toward the prevention of the propagation of consumption consists in the prohibition of the intermarriage of tuberculous subjects. If a man has tubercular disease he should not be allowed to marry a healthy woman, and thus subject her to the danger of contracting the malady from cohabitation with her

<sup>\*</sup> Report of Dr. Hermann M. Biggs to the Health Department of New York City.

consort, to say nothing of the liability of propagating tuberculous offspring. For like reasons a tuberculous woman should be prohibited from marrying a healthy man. But if there are cogent reasons why these should not intermarry there are still more forceful arguments that may be offered against the intermarriage of two tuberculous individuals-that is to say, a man and a woman who either have tuberculous disease or who have come from tuberculous families. I make this assertion at random without desiring at this time to enter into a discussion as to whether the laws of heredity govern in consumption or not. But of this I am certain, that for a man with existing tubercular disease to marry a woman of tubercular parentage would be tempting fate with a rude audacity deserving a better cause. The offspring of such a marriage, to say the least, would offer a favorable soil for the growth of the tubercle bacillus. I earnestly hope that before long an enlightened legislature will enact statutes that will prohibit such marriages.

Still another step in the direction of prevention consists in the establishment of separate hospitals for consumptives and the adoption of measures looking toward their isolation. But here most bitter opposition will be encountered from those who are governed by sympathy, affection, and kinship. Nevertheless, it were well-nigh impossible to prevent the spread of this fateful malady unless the methods and habits of life of its victims can be assuredly controlled. It is admitted by those most familiar with the methods of the propagation of the disease that the sputum of the consumptive constitutes a focus of special danger. Hence, to deal intelligently with the question of prevention, the sputum must be sterilized as soon as it is thrown off. Nor will it answer to deal with it in a half-hearted, indifferent, or slipshod manner; the sterilization must be absolute and immediate, and this can only be accomplished under the eve of a trained expert who knows no law but that of perfect cleanliness and absolute sterilization, and who will not be diverted from the end in view by fear, favor, or affection. I know of no way to effectively enforce rules to prevent the propagation of consumption, except to remove tuberculous persons from all possibility of contact, direct and indirect, with the healthy community.

Without doubt, independently of the infection by food, the most serious menace comes from the respiration of infected dust, and it needs no specious ratiocination to prove to such an audience as this that the one great means of infecting dust is through the sputum of consumptive patients. It has recently been said by a writer in the British Medical Journal that it would be well for the medical profession at large to recognize the infectiousness of tuberculous sputum and the danger of letting it dry into dust. Marpman (Centralblatt für Bacteriologie und Parasitenkunde, Band xlv, 8, pp. 228-234; Med. Chron., November, 1893) examined the dust of a frequented street in Leipsic and found the bacillary remains on about eighty per cent. of samples of dust examined. From the researches of Marpman we are taught that street dust may easily prove a source of infection, and that people should be taught to desist from expectorating in thoroughfares or public places. Houses

that have been occupied by consumptives, too, should receive the most thorough renovation before further use.

It can not be denied that already much has been done to limit the spread of tuberculosis, as a careful examination of statistics would prove, but these we have no time here and now to enter into. The results already accomplished have been outside of the prevention of intermarriage, inspection of food, attempt at isolation, or sterilization of sputum, and have been mainly achieved through the adoption of improved sanitary regulations—better nutrition, purer air, and other influences of like character.

I stand here to plead for the enforcement, in addition to these well-known sanitary measures, of the prevention of intermarriage, of the rigid inspection of animals that furnish food, and the isolation of tuberculous patients, and I ask this academy to stand together as one man until it has brought about such a change in public sentiment and improved statutory law as shall make all these conditions possible. I believe it will be yet just as possible to quarantine and control the methods and habits of life of the consumptive as it is now those of a small pox, yellow fever, or cholera patient. At all events I certainly hope that an enlightenment of the people on this subject will lead to such results.

#### TYPHOID FEVER.

Turning from the consideration of tubercular disease, we approach another infectious malady which has attracted the attention of physicians and sanitarians for more than a generation. In July, 1845, Dr. Austin Flint, Sr., then of Buffalo, and afterward one of your distinguished academicians, published in the American Journal of Medical Sciences an account of an epidemic fever which occurred at North Boston, Eric County, N. Y., during the months of October and November, 1843.

It appears that in September, 1843, a voung man from Massachusetts stopped at Fuller's tavern in North Boston. He had been unwell for several days, a diarrhea being among the most prominent and early of his symptoms; he was first seen by a physician only six days before his death, who found him suffering from diarrhea, low muttering delirium, sordes, and other symptoms that grouped we nowadays characterize as a typhoid condition. He lived twenty-eight days, and from this case the fever spread to other members of Mr. Fuller's family and to those living nearest to his house. Seven of Mr. Fuller's family had the fever, of whom three died. Twenty-one other cases occurred in five families, all being within ten rods of Mr. Fuller's house, of whom seven died, making in all, including the stranger, twenty-eight cases and ten deaths. whole population of the hamlet amounted to forty-three persons; none were attacked who were over twenty-three years old; the youngest was only a year old, and a large proportion were children.

Dr. Flint visited the locality of the epidemic, during which time he made a post-mortem examination of the body of a child about twelve years old, and took notes at the bedside of the histories of nine cases, together with symptoms presented at the time of his visit. It was his first distinguished success as an investigator. He found

and diagnosticated a fatal disease then unknown in western New York, traced it from New England to the hamlet of North Boston, distinctly established its contagion, and found its focus in a particular well of water which had been poisoned by the excreta of an original case. Further use of this well was prohibited. The cases then existing recovered and no new ones appeared. The work was done with all the precision and completeness that characterize the very best detective work coupled with all the skill and acumen of the scientific clinician. Nothing was omitted that would contribute to the completeness and convincing power of the evidence adduced, and the published report has become a classic in this country and in Europe. It also formed a basis of a series of essays that Dr. Flint subsequently wrote on typhoid fever.

Thus was established for the first time a direct relationship between poisoned excreta and the contagion of typhoid fever. I wish we also could say that there had been established an absolute knowledge of the contagium of this destructive malady and the methods of its implantation. Who can say to-day with absolute certainty that the infection of typhoid can be prevented in a given case? Who has yet been able to solve the subtlety with which the bacillus of typhoid fastens itself upon the organism, or who can say what is the most favorable soil for its implantation? Medical societies are constantly debating these questions, and the pages of medical journals are teeming with learned expositions of the various and manifold minutiæ of the subject. I listen to these debates and am, to a certain extent, familiar with journalistic literature. Yet I fail to find a satisfactory answer to the various questions bearing on the communicability of typhoid or any final and determined method of preventing its propagation. There are nearly as many opinions on these several details as there are participants in the debates or writers in periodicals. All this indicates that there is much yet to be done in experimental research, clinical observation, and bacteriological study in relation to typhoid fever. If a conclusion is ever to be reached thereon that will be accepted as final by the profession, it must be through the combined efforts of clinicians, pathologists, bacteriologists, and sanitarians. In the city of Chicago alone, from January 1, 1890, to November 1, 1893, there have been, according to published reports,\* five thousand and eighty-seven deaths from typhoid fever-an average of a hundred and ten a month. This indicates that during this period there have been between thirty and forty thousand cases. There are, says Vaughan, annually fifty thousand deaths in this country from typhoid fever, and half a million sick with it. If it were possible to estimate the money lost to the community in salaries, wages, and expenses from this one disease, the sum would be something enormous to contemplate, and yet there is a great outcry in most cities against the ordinary expenses of the health department. This embarrasses the officials, and the evil should be corrected through an enlightenment of the masses on the subject.

If their sympathies can not be reached from the humanitarian side of the question, then their interests must be appealed to from its economic aspects.

#### DIPHTHERIA.

Similar statements may be offered with reference to diphtheria. Who can say what is the precise method of the propagation of this subtle poison? Who has yet ventured to tell us absolutely how it enters the system, what is its favorite soil, and why under apparently like conditions one individual contracts the disease, while another has only a mild malaise, and still another goes scot-free? Who has told us with absolute certainty what part mephitic vapors play in the causation of this disease? In nearly all the large cities of the world during every month of the year cases of diphtheria are reported ranging all the way from a few scattering victims to many hundreds and even thousands, with a fearful percentage of mortality. Here is another field where moot points are many, opinions widely differ, and satisfactory conclusions are still in the air. Shall it be said during all the future years that diphtheria baffles all attempts at prevention-that it paralyzes the efforts of the medical profession to control it or to fix its habitat? This would be a sad confession of weakness, and a stigma upon the science of medicine that ought not to be permitted to remain. Let us address ourselves to the study of its prevention with an assiduity that will at least deserve success.

### GONORRHEAL INFECTION IN WOMEN.

But one other example, yet in a most important field, will be cited at this time. I refer to gonorrheal infection in women. It is doubtful if any disease is capable of propagating more of sickness, woe, and misery than a neglected or uncured gonorrhea. In view of recent researches, and especially of clinical experiences evolved at the operating table, it is now admitted that what was taught and written relating to the treatment of this infection prior to 1872 was little better than so much chaff; and this remark applies with equally cogent force to the acute stage in the male as in the chronic stage in the female. Though it is true that the medical profession gave little heed to the notes of warning sounded by Noeggerath when he published his opuscule in 1872, now, after twenty years of continual hammering, the foremost men in medicine have finally become aroused to the dangers that lurk in an uncured or latent gonorrhea. This is especially true of genito-urinary surgeons and of those gynæcologists who practice pelvic surgery. Other specialists and clinicians who listen to their debates and read such convincing expositions of the subject as have been given on the one hand, for example, by your distinguished academician Brewer, and on the other hand by Cushing, of San Francisco, have accepted in a measure their teachings.

Brewer has conclusively demonstrated in a clinical history that after six years had elapsed since infection, and where upon examination no secretions could be pressed from the urethra, yet endoscopic examinations revealed granular patches and congested areas in the neighborhood of the bulb and behind a stricture of large caliber measur-

<sup>\*</sup> Med. Record, December 30, 1893,

<sup>+</sup> Med. News.

ing 33°. In this case the microscope showed several characteristic colonies of gonococci. Six weeks afterward, contrary to advice, this man married, and two weeks later had communicated the infection to his wife, in whom it went through the various stages of inflammation and resulted in abscess.\*

Cushing has shown that a woman who had been infected five years previously, without intermediate exposure, finally married and infected her husband, who had a severe urethritis, which resulted in a perineal abscess. Cushing removed both tubes and ovaries, that were distended with pus, in which gonococci were found. The secretion from the urethra of the husband was examined and gonococci demonstrated without difficulty. Here, then, are two cases: one in which the infection was carried by the male for six years and then communicated to his newly wedded wife, and the other in which it was carried by the patient for five years and then communicated to her husband, who had all the symptoms of acute gonorrhea resulting in abscess.

I have cited these two examples as types of this disease, showing its subtlety, how it lurks in some nook or cranny of the genital tract for years, thence to be conveyed to an innocent spouse or consort, in whom it lights up a disease that ravages the entire pelvic cavity. The list might be prolonged indefinitely, but this is neither the time nor place to recite lengthy clinical records.

Only within the last few years have physicians been ready to admit the terrible destructiveness of this malady. Until lately most physicians or surgeons who have been called upon to treat the disease in its acute stages, whether in the male or female, have generally regarded it in a light or trifling manner, contenting themselves for the most part with ministering to the first distress, but paying little heed to its secondary probabilities. The victims of this disease, too, have been taught to regard it as a mere trifle, that a few urethral or vaginal injections and a few doses of copaiba would assuredly cure without danger of any secondary complications, and that even a long-standing gleet had little or no significance beyond the mere personal discomfort that it caused. Only the few even consulted physicians, while the many borrowed a syringe and a prescription from a friend, or obtained the same from a kindly and sympathizing druggist, who, for a few shekels, is ever ready to assure the sufferer that his disease is of slight consequence, that he will be well of it in a few days, and that all he needs is a few injections with "No. 1" and a few days' dosing with "No. 2."

The literature of this disease is being almost entirely rewritten, and the teachings of the schools are recasting in view of the awful consequences of neglect to cure or prevent the propagation of this subtle, deceptive, and virulent infection when once it has been contracted. It has come to pass that a woman who accepts an offer of marriage finds

herself treading upon dangerous ground-a danger far more serious than those contemplated by Mother Eve when she entailed her sex-and it becomes a problem of the most serious import when her answer may fetch her to a spring of woes unnumbered. I speak seriously, for it is a subject that demands our most thoughtful consideration. If we would stamp out the frightful malady, or even prevent its propagation to innocent persons, we must, as a profession, exert ourselves to the utmost to bring enlightenment to the people and to enforce an intelligent application of the laws of prevention. We have been taught to regard syphilis as the most destructive of the venereal diseases, but I believe gonorrhœa to be a far more serious disease than syphilis, and that it plays more dreadful havoc with the community. We are seeing constantly fewer and fewer syphilities, while gonorrhoics are increasing in number, and the secondary consequences of the disease are becoming better understood. I am well aware that difficulties surround this subject almost greater than any other, owing to its extreme delicacy; nevertheless, the fullness of time has arrived when action must be taken to arrest a disease that leaves such horrible consequences in its track, and I appeal to this academy to formulate and carry out some plan that shall have for its purpose the enlightenment of the community, the education of physicians, and the enactment of such statutes as shall prevent others than physicians from prescribing or in any manner giving advice as to the treatment of gonorrhea.

### CONCLUSIONS.

In my early youth I learned to look to the New York Academy of Medicine as the leader of medical thought in this country. My father, a physician, so taught me, as a child receives impression from the hornbook on his mother's knee. It is here that medical men from all quarters of the globe are received and entertained at your meetings and go away with new inspirations, renewed energy, and increased intelligence. This academy becomes perforce a mighty instrument for the advancement of medical science and improved methods in medical art. One of the great orators of this metropolis asseverated in his speech at Chicago on Manhattan day that the World's Fair had taught us that art was more godlike than science, for, while science discovered, art created. I believe this applies as well to medicine as to other arts and sciences. I ask you to remember that I am not unmindful of the great work this academy has inaugurated from time to time during its history with reference to the prevention of disease, nor of the fact that it is still laboring with might in that field. When this academy speaks the world moves. When she asks that certain methods and certain means be adopted with reference to improvements in quarantine, they are done. When she recommends the board of health to adopt certain measures with reference to the details of preventive medicine, the board at once accepts its conclusions and adopts them. It has gratified me to observe very recently the splendid action taken by the academy with reference to the creation of a National Bureau of Health, and I sincerely hope its recommendations may be given form and

<sup>†</sup> Contribution to the Study of Pelvie Diseases. Transactions of the American Association of Obstetricians and Gynacologists, vol. i, 1888,

force in the immediate future through national statutory law.

But it is not as sanitarians, or public health officers, or as administrators of state medicine that I appeal to this Academy of Medicine. I beseech you, each and every one, in your capacities as individual members to do your parts toward inaugurating a fashion that shall have for its purpose discussions relating to the prevention of disease at the general meetings of this academy to the exclusion of all other scientific work. The report of these proceedings given to the medical journals and published as ex cathedra edicts will arrest the attention of physicians all over the world, and thus serve to begin a campaign of education on the several questions to which I have called attention, as well as many others that for obvious reasons could not be specified on this occasion. I have merely attempted to accentuate those that seemed to me of greatest importance. Cholera, small-pox, and even yellow fever are no longer re garded as plagues of humanity, but consumption, diphtheria, typhoid fever, and gonorrhea are slaying or invaliding unnecessarily hundreds of thousands annually.

The laity must be educated to regard consumption as a communicable disease, and to accept laws and regulations calculated to restrict its propagation and restrain its victims within the limitations of safety, so far as uninfected individuals are concerned. But rules, too, must be formulated for the prevention of the spread of diphtheria and typhoid, and these must be insisted upon without deviation, and the community must learn to yield a hearty support to such beneficent and humane methods as have for their sole and distinct object the protection of the individual. Finally, I hope that this academy will address itself seriously to the eradication, prevention, and cure of that loathsome, subtle, and destructive disease gonorrhea, that is directly and indirectly bringing to invalidism or death so many innocent thousands throughout the civilized world. I am well aware that all these questions are as well or better known to you than to me; I am only attempting to recall them to your minds for the purpose of stimulating or encouraging renewed energy in their consideration.

Pardon me, Mr. President, if I have said more than I ought to have said, or more than there was occasion to say. I have spoken from a deep conviction of the importance of the subject, and with a realizing sense that I am standing in the presence of men who are doing as much or more than any other group of equal number toward the prevention of the diseases in question, as well as others that have not been mentioned. I know, too, that your sections are made up of recognized men of exceptional skill in their several departments, and whose work goes out every month to the professional world in brilliant and well-recorded achievements. Your orthopædists are restoring hundreds of maimed children to usefulness and self-support; your ophthalmologists are restoring to sight thousands of eyes every year, and are preventing the beginning of destructive processes in many thousands more; your gynæcologists are restoring to health numberless invalid women -wives, mothers, and sisters-who would otherwise drag through life a miserable existence or obtain all too early

sweet relief in death; and so on through the entire list of your splendidly organized sections. But in spite of all this, let me implore you to set apart at least one meeting in every month, if not both, where all the splendid talent of these sections shall merge itself for the discussion of problems relating to the prevention of disease; and I venture to hope that these discussions may assume that particular form which will prove valuable to individual physicians who are battling with disease in the smaller towns, hamlets, and remote points in the land, and who are known and properly designated as family doctors. These are the men who need your aid, who deserve the stimulus of your best thought, and the inspiration of your example. As a final word let me enter a plea in their behalf to the end that your literature be sent to them with a liberality so characteristic of your organization, and that they be invited when practicable to attend your meetings.

Mr. President, it remains for me to thank you for the distinguished honor you have conferred upon me in inviting me to address this academy at this time. I apppreciate it more than mere words can express. Yet I regret that I have so inadequately fulfilled the responsibilities of the high office you have so kindly thrust upon me. But I assure you, sir, that I shall carry with me down to the crack of doom the memory of this pleasant visit to the New York Academy of Medicine.

284 FRANKLIN STREET.

# ON GUAIACOL APPLIED EXTERNALLY AS AN ANTIPYRETIC.

By JULIUS FRIEDENWALD, A.B., M.D., VISITING PHYSICIAN TO BAY VIEW HOSPITAL.

AND H. H. HAYDEN, M. D., RESIDENT PHYSICIAN TO BAY YIEW HOSPITAL, BALTIMORE.

Sciolla\* was the first to point out that guaiacol, when applied to the skin, acted as a powerful antipyretic. He used this remedy especially in tuberculous cases and found that two to ten grammes of guaiacol painted upon the skin of the limbs, back, or abdomen (the parts being then covered with gauze or gutta percha) produced a reduction of temperature in fifteen minutes, the patient tasting the remedy. The first traces of guaiacol were noted in the urine in one hour, the largest quantities in from four to six hours. The temperature fell in four to six hours from 2° to 3° C. and then gradually rose. He obtained the same results in various other febrile diseases. Pure guaiacol never produces any inflammatory condition of the skin.

He was soon followed by Bard and Lannois,† who confirmed Sciolla's statements. The treatment, according to Lannois, is suitable for cases of tuberculosis except those in which there are cavities in the lungs. The drug was rubbed over the chest, back, or thigh, the part being afterward covered with a dressing.

<sup>\*</sup> Sciolla. Cron. d. Clin. Med. di Genova, 1892-'93, i, 171-176; also Semaine médical, 1893, No. 21.

<sup>†</sup> Lannois. Lyon médical, 1893, lxxiii, 459-464.

Robillard\* also confirmed the statements of Sciolla concerning the antipyretic action of guaiacol when applied externally.

Cassovice and Sigalea † applied the drug in combination with tincture of iodine (one part of guaiacol to five parts of the tincture of iodine) in the treatment of pleurisy. This was painted over large surfaces of the thorax in the evening. A fall of temperature, profuse perspiration, and an increased flow of urine followed; complete resorption of the pleuritic effusion resulted.

Guinard, ‡ after making numerous experiments concerning the effect of the local application of this drug, concludes that the fall of temperature is due to an effect upon the heat center in the brain produced reflexly through the peripheral nerve terminations, and to a slight degree to the inhalation of the vapor of the drug. The effect is more marked in febrile than in non-febrile conditions.

Stolzenburg,\* who made similar observations with this drug, finds that the fall of temperature lasts five to eight

A chilly sensation or chill is frequently produced and sometimes collapse. The initial dose should never be above two cubic centimetres.

Quite recently Da Costa | reports his experience in the use of this drug. He finds that marked reduction of temperature is produced when guaiacol is simply painted over the skin with or without friction. In a case of typhoid fever the temperature fell from 105.4° F. to 98.6° F. in three hours and a half. The reduction of temperature is rather slow, but is not accompanied by any disturbance of the nervous system; a chill was noted in but one case, There was no increase in debility; no delirium; no depression or sign of collapse. In a case of pneumonia the striking effect of guaiacol upon the temperature was not so manifest as in typhoid fever, though the temperature did fall two degrees. The special advantage of guaiacol is its use in typhoid fever when the cold bath can not be applied. While the reduction of temperature following the application of guaiacol is slower than after the bath, the effect is more permanent. As regards the dose, Da Costa believes that the maximum should not be over fifty drops, and so large an amount should rarely be used. Thirty drops is the average dose. After washing the parts with soap and water the guaiacol is applied and rubbed in slowly.

Our experience with guaiacol is based upon its use in seventeen cases. In all, the skin of the abdomen was washed with soap and water, the parts were dried, and the drug was rubbed in for fifteen minutes and covered. There were eight cases of pneumonia, two cases of typhoid fever, two cases of pulmonary tuberculosis, one case of malarial fever, two cases of influenza, one case of rheumatism, and one case of erysipelas.

pneumonia.

Case II. Pneumonia.—W. F., aged twenty-eight years, admitted February 26, 1894; had a severe chill two days before admission into hospital; also had pain in the chest and fever. On examination, the right lower lobe was found consolidated. Temperature, 103° F., which soon ran up to 105° F. at 4 P. M. Thirty drops of guaiacol were applied, and the temperature fell to 103° F. at 5 P. M., but was again up to 105° at 6 P. M. A bath was given, and the temperature fell to 101° at 8.30 P. M., but was again 104° at 9. P. M. and 105° at 10 P. M. The temperature fell the next morning (February 27th), but at 3 P. M. of this day was 105° F. Thirty drops of guaiacol were applied, and the temperature fell gradually to 101° at 5.15 P. M., but at 7 P. M. was again 103°8° and at 9 P. M. 104° F.

Chilly sensations, profuse perspirations, and great depression and weakness were noted when the temperature had been reduced by means of guaiacol. The bath, which seemed to have reduced the temperature in this case quite as well as guaiacol, did not produce any depression.

Case III. Pneumonia.—W. R., aged thirty-two years, admitted February 27, 1894; had a marked chill two days prio to his admission; also fever, cough, and pain in his chest.

The two upper lobes of the right lung and the upper lobe o the left lung were found consolidated. Temperature at 3 P. M. 104.2° F. Thirty drops of guaiacol were applied, and the temperature gradually fell to 100 6° at 5.30 P. M., but was 106° at 7 P. M. A cold bath was given, and the temperature fell to 102° at 7.30 P. M., but was 104° at 11 P. M. At 3 P.M. on the following day (February 28th) the temperature was 104° F., but was reduced by a bath to 101.4° at 4 P.M. It ran up gradually to 104° again at 11 P. M. At 3 P. M. on the 1st of March the temperature was 104.6°, and at 3.30 104.4°. Thirty drops of guaiacol were applied, and the temperature gradually fell to 100.4° at 6.15 P.M. At 8 A.M. the next morning it was but 102° F. Chilly sensations were noted in this case after the use of guaiacol; also profuse sweating and depression. The guaiacol reduced the temperature more gradually and lower than the bath, but the bath produced less depression.

Case IV. Pneumonia.—M. G., aged thirty-three years, admitted March 7, 1894; had a severe chill on March 5th, followed by high fever. On examination, consolidation of the lower lobe of the right lung was noted. At 10.15 a.m., March 8th, the temperature was 104°. Thirty drops of guaiacol were applied, and the temperature fell gradually to 101° at 12 noon. At 1 p.m. the temperature was again 104°. At 11.45, March

Case I. Pneumonia .- S. C., aged thirty-five years, admitted into hospital February 6, 1894; taken ill on February 2d; had no chill, but felt badly and had fever and suffered with cough and pain in the chest. The examination showed consolidation of upper lobe of left lung. The temperature was 102° F.; at 3 P.M. it rose to 103.6° F.; at 3.30 P.M. to 103.4° F.; thirty drops of guaiacol were applied and the temperature fell gradually to 100.4° F. at 4.30 P.M.; it rose, however, at 5 P.M. to 101° and at 6 P. M. to 104°, when thirty drops of guaiacol were again applied, and the temperature gradually fell to 100° F. at 8 A. M. the next morning (February 7th). After this it never rose above 102° F. until February 11th; at 6.45 P. M. the temperature was 104° F.; thirty drops of guaiacol were again applied and the temperature fell to 100° at 8.30 P.M.; at 10 P. M. it was again 108°, but fell from this time on of its own accord. The application of the guaiacol in this case produced profuse diaphoresis; no chill or chilly sensations were noted. Great exhaustion was experienced by the patient at the time of the fall of temperature. It is interesting to note that the temperature of this patient never became normal, and that he has since developed tuberculosis in the same lung in which he had

Da Costa. Medical News, January 27, 1894.

9th, the temperature was 104°. Thirty drops of guaiacol were applied, and the temperature fell gradually to 102° F. at 1 P. M., but rose to 104.4° at 3 P. M., whereupon a bath was given, and the temperature fell to 101.4° and did not rise again above 103° F. In this case no chilly sensation or depression was noted after the application of guaiacol. Profuse perspiration was, however, produced by the drug.

April 14, 1894.]

Case V. Pneumonia.—J. C., aged thirty-six years, admitted March 9, 1894. Patient had a chill just before entering the hospital. He complained of fever, cough, and pain in his chest.

On March 10th consolidation of the lower lobes of the right and left lung was noted. On this day, at 8 a.m., the temperature was 105°; at 8.30, 104°. Thirty drops of guaiacol were applied, and the temperature fell to 102° at 9.30, but was again 104° at 11 a.m. A bath was given, and the temperature fell to 101·6° at 12 noon, but at 3 p.m. was again 104°, and another bath was given. The temperature fell gradually, and never became high again. The guaiacol did not produce a chill or chilly sensations in this case, but marked depression was noted; no depression was caused by the use of the bath.

Case VI. Pneumonia.-J. F., aged thirty-seven years, admitted March 9th; had had a chill on the 7th of March, which was followed by high fever. On examination, the upper lobe of the right lung was found consolidated. On March 10th, at 10 A.M., the temperature was 104.6°. Thirty drops of guaiacol were applied, and the temperature fell gradually to 101.4° at 12 noon, but arose gradually to 103° at 9 P.M. At 8 A.M., March 12th, the temperature was 104°. Thirty drops of guaiacol were again employed, and the temperature fell to 100° at 11 A.M., but was 103° at 3 P.M. This patient felt a chilly sensation after the use of the guaiacol, but no depression. He perspired profusely. Again, on the 13th of March at 3 P. M., his temperature was 104.4°, and a bath was given which reduced his temperature to 101°. The effect produced by the bath was not so marked or pleasant as that produced by guaiacol, and when, on the 14th, it was again necessary to reduce his temperature, he preferred the guaiacol to the bath. The guaiacol reduced the temperature again from 104° to 101°.

Case VII. Pneumonia.—William M., aged fifty-five, admitted March 10, 1894; had a chill three days before entering hospital, followed by fever and tightness on chest. On examination, the lower and upper lobes of the right lung were found consolidated. At 8 a.m., March 11th, the temperature was 104-2°. Thirty drops of guaiacol were applied, and the temperature fell to 100° at 10 à.m.; it rose to 103° F. at 3 p.m., but after this time fell without the use of any antipyretic. The patient experienced no chill after the application of the guaiacol, but suffered markedly from the profuse diaphoresis produced by the drug.

Case VIII. Pneumonia.—J. D., aged thirty-one years, admitted March 11, 1884. On the morning of admission had a chill followed by fever. Examination on March 12th revealed a consolidation of the apex of the right lung and of the base of the left lung. On this day at 11.30 a. M. the temperature was 103.4°. Thirty drops of guaiacol were applied, and the temperature fell to 102° at 1 p. m., but was again 103° at 2 p. m. On the 13th, at 11 a. m., the temperature was 104°; a bath was given, and the temperature fell to 101° at 11.50 a. m., but rose to 104.6° at 3 p. m. Thirty drops of guaiacol were now applied, and the temperature fell to 101° at 6 p. m., but again rose to 105° at 9 a. m. This temperature was again reduced by a bath. No chill or chilly sensation was noted in this case. After guaiacol had been applied the patient felt weak, and suffered from profuse diaphoresis.

Case IX. Typhoid Fever.—R. S., aged twenty-five years, admitted February 5th; had been previously in good health.

Four or five days before admission to the hospital he had suffered from profuse diarrhea, malaise, and epistaxis. When admitted the patient had profuse diarrhea (typhoid stools) and tympanites; no special pain or tenderness over the abdomen. On the 6th of February, at 10 A. M., the temperature was 103.6° F.; thirty drops of guaiacol were applied and the temperature fell to 101° at 12 M.; it rose gradually and at 6 P. M. was 104.6°, whereupon thirty drops of guaiacol were again applied; the temperature fell gradually to 102° at 9 P. M. and did not rise until 6.45 P. M. the next day, when the thermometer registered 104°; thirty drops of guaiacol were again applied and the temperature fell once more to 101° F. at 8.30 P. M.

At 8 p. m. on the 8th the temperature was 103.6°; a cold bath was given and the temperature fell to 102.8° at 3 p. m., and did not again rise until the 10th, when, at 9.30 a. m., the temperature was 103.6°; thirty drops of gnaiacol were applied at this time and the temperature fell to 100° at 5 p. m., but at 6 p. m. rose to 108°. The application of gnaiacol did not produce any marked chill or chilly sensation in this case, but the profuse perspiration which the remedy caused was very exhausting to the patient. The bath which was applied reduced the temperature as well as the gnaiacol without causing the intense exhaustion.

Case X. Typhoid Fever .- R. L., aged twenty-four years, admitted February 11, 1894. Patient had been ill a week before admission into hospital; he had suffered with profuse diarrhœa, feeling of malaise, headache, and fever. On admission the abdomen was found distended and very tender to the touch; the diarrhea was still profuse. At 1 P. M. the temperature was 104°. Five grains of antipyrine were administered and no reduction of temperature was noted. The temperature was 105° at 4.15 P.M.; thirty drops of guaiacol were applied and the temperature gradually fell to 102° at 6 P.M.; it rose gradually again until 12 at night, reaching 104°. At 12 o'clock noon the next day the temperature was 105 8°; forty drops of guaiacol were applied and the temperature gradually fell to 101.4° at 3 P.M. At 6 P.M. it was again 105°; a bath was given and the temperature fell to 104° at 6 P. M.; at 7 P. M., the temperature still being 104°, ten grains of antipyrine were administered and the temperature fell to 108.4° at 11 P. M.

On the 13th, at 3 P.M., the temperature cose to 105°; forty drops of guaiscol were again applied and the temperature fell gradually to 100°6° at 6 P.M., but rose to 105° again at 8 P.M. A cold bath was next administered and the temperature fell to 102°6° at 11 P.M., but rose to 104°4° on the following morning at 10.30. Forty drops of guaiscol were now applied and the temperature was reduced to 99° at 2 P.M., but at 4.30 P.M. was again 105°.

In this case guaiacol produced a marked chill and great depression and profuse sweating, and the patient became very weak and exhausted. While the bath did not lower the temperature so markedly as the guaiacol, the effect produced was more stimulating and refreshing and no depression was noted.

Case XI. Pulmonary Tuberculosis.—F. O., aged forty-five years, admitted February 2, 1894. Patient has had cough and night sweats for the past five years; has also expectorated blood at times.

On admission, apices of both lungs were found consolidated. On February 3d at 6.15 p.m. the temperature was 103.6° F.; thirty drops of guaiacol were applied and the temperature fell gradually to 99.2° at 9 p.m.; it gradually rose, however, during the night, and at 7.30 a.m. the next morning was 103°. The application of guaiacol occasioned such profuse perspiration, marked depression, and weakness that it was not again applied in this case.

Case XII. Pulmonary Tuberculosis.—G. D., admitted February 15, 1894; patient had been ill some time before admission; suffered with cough, expectoration, and night sweats. On examination the entire right pleural cavity was found to contain fluid; this was removed by aspiration and the apex of right lung was found consolidated.

On the 15th, at 6.30 A.M., the temperature was 104° F.; thirty drops of guaiacol were applied, and at 9 P.M. the temperature had fallen to 101.8°, and at 11 P.M. was again 104°.

On the 16th, at 5 P.M., the temperature was 104°; forty drops of guaiacol were applied. At 6 P. M. the temperature was 103°, and at 7 P. M. 104°. Five grains of antipyrine were administered and the temperature fell to 101.4° at 9 P. M., and did not rise again until 12 noon the following day, when the temperature rose to 104°; with five grains of antipyrine the temperature was again lowered to 101° at 2 p. m., but rose to 104° at 11 P. M. At 3.45 P. M. the same day the temperature was 103.4°. Thirty drops of guaiacol were again applied, but the temperature rose to 104° at 5 P. M. In this case, in which guaiacol was applied on three separate occasions, the temperature upon the first occasion was reduced from 104° to 101.8° and quickly rose again to 104°. In the second and third instances the temperature was not reduced at all, while five grains of antipyrine markedly reduced the temperature. Other trials were made with guaiacol upon the same patient, but in no instance were we able to produce any marked reduction of temperature; marked diaphoresis and depression were, however, noted.

Case XIII. Malarial Fever.—J. H., aged forty-six years, admitted March 3, 1894. Has had a chill every second day for two weeks; suffered with malaise, headache, and pains in the back and loins. Patient had a chill on day of admission; malarial organisms were present in the blood. At 8 P. M. the temperature was 104° F. Fifty drops of guaiacol were applied and the temperature gradually fell to 100·6° at 9 P. M. At 11 P. M. the temperature had again risen to 108°, and five grains of quinine were given at this time and ordered three times daily, and, as the temperature continued to rise to 104°, at 5.15 P. M. fifty drops of guaiacol were again applied and the temperature fell to 101° and did not again rise. The guaiacol did not produce any chilly sensation in this case, but caused profuse diaphoresis and weakness.

Case XIV. Influenza.—E. G., aged thirty-five years, admitted into the hospital March 1, 1894. Patient has had pain in the head and loins and a feeling of malaise for several days. On the day of admission the temperature was 104.6° F. at 9 P. M. Thirty drops of guaiacol were applied, and the temperature gradually fell to 101.4° at 11 P. M. On the second day the temperature had risen to 105.2° at 11.40 A. M. Thirty drops of guaiacol were again applied; the temperature fell to 103° at 1 P. M., but at 3 P. M. had risen to 104.4°; with five grains of antipyrine the temperature was gradually reduced to 101° at 3 A. M. the following morning. The guaiacol applied in this case produced neither a chill nor chilly sensation, but profuse diaphoresis which occasioned great prostration. The temperature was reduced quite as well with the guaiacol as with the acetanilide, and the same prostration and diaphoresis were noted when the antifebrin was employed.

Case XV. Influenza.—M. D., aged thirty-one years, admitted March 8, 1894. Patient had a chill the night before admission; since then has been feeling badly with, pains in his limbs, headache, nausea, and loss of appetite. At 3 P. M. on the 8th the temperature was 104° F.; thirty drops of guaiacol were applied. The temperature fell to 101'6° at 4.80 P. M., but rose gradually to 104° at 6 P. M. Ten grains of antipyrine were

administered, which reduced the temperature to 102° at 9 P. M., and it did not again rise.

No chill, chilly sensation, or depression was noted after the use of guaiacol. The patient felt better after the use of the drug than before it had been applied.

Case XVI. Acute Articular Rheumatism.—W. G., aged thirty-eight years, admitted March 5, 1894. Had severe rheumatic pains in left wrist, knee, and ankle, with swelling of these joints. At 8.15 p. M. ou the day of admission the temperature was 104° F.; thirty drops of guaiacol were applied and the temperature fell gradually to 102° at 9 p. M. This case was subsequently cured with salicylate of sodium.

The guaiacol produced marked perspiration, but no chills or chilly sensations were noted. Marked prostration was, however, noted.

Case XVII. Facial Erysipelas.—G. T., aged thirty-five years, admitted into hospital March 16, 1894. The temperature at 4.45 p. m. of the same day was 104.6° F. Thirty drops of guaiacol were applied. At ten the next morning the temperature had only fallen to 103°. Thirty drops of guaiacol were again applied and the temperature gradually fell to 100° at 1 p. m. The patient had no chill or chilly sensation after the use of guaiacol, but felt better; no weakness or prostration was noted.

From these observations concerning the external application of guaiacol in fever we are justified in concluding:

- 1. That this drug has a powerful antipyretic action, occasioning a reduction of from one to four degrees of temperature in from one to four hours.
- 2. That in all cases this reduction of temperature is accompanied by profuse diaphoresis, which may or may not be accompanied by a chill or chilly sensation.
  - 3. That great exhaustion is frequently produced.
- 4. That the effects may be obtained from comparatively small doses (from thirty to fifty drops), and that great care should therefore be exercised in the use of the

April 14, 1894.]

drug. The drug should be applied but once or twice daily, and the initial dose should not be above thirty drops.

- 5. That the effect produced by guaiacol, though more powerful, is the same as is obtained from most of the other antipyretics of the coal-tar series, and that the same care must therefore be exercised as with the other preparations. Its effect differs from the stimulating cold bath in being depressant.
- 6. That the main indication for its use is in diseases accompanied by high fever in which the cold bath can not be applied. It may therefore be especially useful in typhoid fever as well as in all other diseases accompanied by high fever in which irritability of the stomach prevents the use of other antipyretics.

Note.—Since the foregoing was written an article by Dr. W. S. Thayer on Notes on the Value of Guaiacol Applied Externally as an Antipyretic has appeared (Medical News, March 31, 1894). His results agree essentially with those obtained by us.

## A BRIEF NOTE ON SOME CASES RECENTLY ADMITTED TO THE SURGICAL SERVICE AT THE NEW YORK CANCER HOSPITAL.\*

By CHARLES A. POWERS, M. D., SUBGEON TO THE HOSPITAL.

As a preface to the hasty remarks which I have to make on the topic embodied in the foregoing title it may be well to sketch, in short order, some of the conditions governing the institution.

Patients with real or suspected malignant disease, with neoplasms of any form, applying at the hospital are admitted to the free wards, and are divided into three classes:

- 1. Operable surgical cases.
- 2. Operable gynæcological cases.
- 3. Inoperable or chronic cases.

It is with the first class that I have to do, and the cases to which I shall briefly refer are those of patients who applied directly to the hospital and were admitted during the four months ending with January 31, 1894, to the active surgical wards. Cases of benign tumors are not included, nor are patients with cancer sent by me from my office to the hospital, or those referred directly to me there by physicians or former patients.

The wisdom of admitting on equal terms supposedly malignant and benign tumors is shown by the very considerable number of instances in which a neoplasm considered benign on admission has proved, on removal, to be malignant.

Examinations for admission are made by the house surgeon, and while in general inoperable cases were referred by him to their proper wards, it so happened in some instances that cases deemed operable by him were thought otherwise by the attending surgeon. These latter are included in the following list:

Cases of cancer of the breast and axillary glands, too

extensive to warrant thought of cure, but seeming to demand the relief afforded by a palliative operation, 8.

Cancer of the breast, inoperable, 4.

Cancer of the rectum, too extensive for removal, palliative inguinal colostomy, 1.

Cancer of the tongue and lower jaw, operation palliative, 2.

Cancer of the face, inoperable, 1.

Cancer of the penis and groin, inoperable, 1.

Cancer of the rectum, not advanced, Kraske's operation, 1.

Cancer of face of limited extent, 3.

Total, 21 cases; one post-operative death, septicæmia after excision of tongue and lower jaw.

As has been said, this list does not embrace cases of benign neoplasm nor those sent into my service direct by others or by myself. If we include the inoperable cases which applied and were admitted to the incurable wards or refused admission thereto because of lack of room, we should add 22 cases, making a total of 43.

It has been my custom, of late, to divide operable cases, after operation, into three classes.\*

- 1. Those in which the disease is so limited that it is thought reasonably probable that it is entirely excised and that the patient has a fair prospect of cure.
- 2. Those cases in which the surgeon is doubtful, after removal, whether he has gone beyond the limits of invaded tissue.
- Cases frankly incurable, in which a palliative operation affords a fair prospect of adding to the life and comfort of the patient.

That some such classification would seem both reasonable and desirable is evident when we come to compute, after a term of years, percentages of the radical cure of cancer. Let us take, for example, that common seat, the female breast. It is manifestly unjust to include in the same category a case in which the cancerous lump in the gland was no larger than a walnut, the axillary glands being free from invasion, and one in which the entire breast is a solid mass of cancerous tissue and the glands of the axilla markedly involved. In the first instance, wide excision of the gland and a thorough dissection of the axilla offers the patient a very good chance of permanent cure.

In the second case operation must be judged purely palliative.

As illustrative instances of this division I may be allowed to cite the following cases recently under my care at the Cancer Hospital:

Case I. First Stage.—Mrs. Y., a lady of seventy years, was referred to me, in January, by her family physician on Long Island.

Two months previously she had noticed a small lump in the right breast. Examination revealed a hard nodule of the size of a small pullet's egg, just above and without the nipple. Noth-

March 26, 1891.

<sup>\*</sup> Read before the Medical Society of the County of New York,

<sup>\*</sup> It is needless to say that no sharp lines can be drawn in any such division. One estimates an individual case as best he can.

<sup>†</sup> These palliative operations are to be recommended whenever we feel that the patients can thereby be rendered more comfortable, due estimate being made of mortality risk.

ing felt in the axilla. Operation: Excision of the entire breast, pectoralis fascia, and axillary contents. A few slightly enlarged glands found in the axilla. Primary union under one dressing.

The pathologist, Dr. E. K. Dunham, reported the breast nodule carcinoma, the axillary glands hyperplastic. Prognosis fairly good.

Case II. Second Stage.—Mrs. X., a woman of fifty-eight years, was referred to me by her physician in Massachusetts, in February of this year. Fifteen months ago she first noticed a small, hard lump at the upper outer quadrant of the right breast. This she showed to her physician, who called it "enlarged milk veins." It slowly increased in size and became painful.

Examination revealed a firm mass of the size of a small mandarin orange in the outer half of the breast, freely movable on the deeper tissues. Skin and nipple normal, nothing felt in the axilla. Operation, February, 1894: Excision of breast and axillary contents. A half dozen enlarged glands were found in the axilla, all within reach of investigation being removed. Primary union; the patient went home on the eleventh day. Pathological report: "Carcinoma of breast and of the axillary glands. There is a good zone of healthy tissue on all sides of the tumor." Prognosis dubious, as one can not assume that all glandular involvement was removed.

Case III. Third Stage.—Mrs. Z., a woman of sixty-five years of age, was brought to the hospital by her physician in December last. Fifteen months previously she had noticed a lump in the left breast. This had slowly but steadily increased in size, its growth being watched with interest and without alarm by the patient and her physician. When admitted the breast was a solid mass of evidently cancerous tissue, lightly adherent to the chest wall.

The skin was reddened and adherent, the nipple retracted.

A mass of the size of a pigeon's egg was felt in the anterior axilla.

Operation: Removal of the breast, pectoralis fascia, the axillary glands, and a part of the pectoralis major. Even after extensive dissection it was evident that all involved tissue could not be removed. Undisturbed healing.

Pathological report: "Carcinoma of breast, glands, and a part of the pectoralis muscle." Prognosis, recurrence certain.

If, now, we refer to the table of cases to which reference has been made, we see that seventeen, or eighty-one per cent., would fall in the class of inoperable or thirdstage operable cases, only nineteen per cent. affording to the surgeon any prospect whatever of a radical cure. And if we add the inoperable cases admitted to the chronic wards or refused for lack of room, we should have of the forty-three cases but nine per cent.which could be placed in the first stage. It may be thought unfair to add these latter cases, as the knowledge that the Cancer Hospital provides accommodation for a number of incurables leads many such to be sent to it for shelter; but I am sure that the contention that the vast majority of operable cancer cases reach the surgeon too late to warrant expectation of cure is one that will be shared by all who have to do with active surgical work.

I have purposely refrained from speaking of the therapy of these cases or making any allusion to ultimate results. I am quite content at this time to call your attention, as has been done so many times before, to the fact that if we are to cure cancer we must attack it very early, while the disease is yet essentially local.

#### MIDDLE-EAR OPERATIONS.

By GORHAM BACON, M. D.

Operations on the middle ear, consisting in removal of the drumhead, wholly or in part, excision of one or of all the ossicles in cases of both chronic purulent and chronic catarrhal otitis media, have been performed frequently during the past seven or eight years by many otologists in this country and abroad, the results being studied with much interest. We are gradually arriving at some definite conclusions.

In regard to the removal of the remains of the drumhead and of carious ossicles in cases of chronic purulent ottis media, where other methods have been tried and have failed to effect a cure, I believe that most surgeons are agreed as to the propriety of recommending such an operation. If after the use of the middle-ear syringe, of cleansing and antiseptic solutions, and of astringents, we fail to cure the discharge, there is no reason why the usual surgical treatment adopted for other carious cavities should not be practiced here, in order to effect proper drainage. This operation can be performed in such cases in a few individuals without general anæsthesia, by means of the local application of cocaine. In children and in adults, as a general rule, it will be useless to attempt such an operation without first giving ether.

Schwartze, in his Deutsche Chirurgie, advised removal of the drumhead with extraction of the malleus and incus in cases of chronic purulent inflammation of the middle ear with caries of the ossicles, and in cases of cholesteatoma of the middle ear. In this class of cases we have the best chance of curing the discharge by an operation, and frequently the hearing distance will likewise be much improved. In cases of long-standing suppuration, however, attended with more or less extensive caries of the walls of the middle ear and antrum, it will be necessary to go further than this operation in order to reach the seat of the disease. To accomplish this we must do a "Stacke operation "-viz., displace the auricle forward and remove a portion of the upper wall of the external meatus-or we must cut down upon the antrum from behind the auricle, and in this way remove any cheesy matter and scrape with curettes all the carious bone. It has been my practice to do the latter operation, and in some instances it is necessary to keep the patients under observation for a long time before ultimate recovery is assured. It is highly important to attend most carefully to the patient's general health. Tonics, cod-liver oil, and a nourishing diet should be prescribed. Tuberculosis, syphilis, and scrofula are important factors in many cases of chronic purulent otitis media.

It is not to this class of patients that the writer wishes to direct attention, but to those patients suffering from chronic catarrhal otitis media, the so-called sclerotic variety. In such, various operations have been proposed and practiced from time to time—such as excision of a piece of the drum membrane, which was first performed in a scientific manner by Himly and Sir Astley Cooper. These surgeons were encouraged at first by the favorable results which they obtained, but finally abandoned the

operation, as the artificial openings generally closed and the former degree of deafness returned. Gruber published a paper on myringodectomy in 1861. Other operations have been division of the tensor tympani muscle and division of the folds of the drumhead. Wreden recommended the excision of a portion of the handle of the malleus, so as to cut off some of the blood supply, and in this way prevent the reforming of the cicatricial tissue. Incisions have also been made with cauterization of the edges of the wound, so as to maintain a permanent opening.

Simrock advised making an opening in the membrana tympani by means of the application of a drop of sulphuric acid on a probe. The galvano-cautery has also been used for this purpose.

Of late years the operation of excision of the membrana tympani and of one or more of the ossicles, first advocated by Kessel and afterward by Schwartze, has been revived and performed by many surgeons in this country and abroad for the relief of deafness, tinnitus, or vertigo, with various results by different observers.

The latest operation to receive the attention of the profession has been stapedectomy. At the annual meeting of the American Otological Society held July, 1892, Blake read a paper on Middle-ear Operations, in which he advised the removal of the stapes in cases of chronic dry catarrh, and said: "My own experience in this matter includes a series of experiments in various cases, beginning with the observations having reference to the diagnostic value of high musical tones, extending up to the present time and including operations in the following sequence:

"1. Excision of the posterior segment of the membrana tympani, allowing the sound waves to fall directly upon the stapes.

"2. Formation of a flap from the posterior segment of the membrana tympani and attachment of it to the descending process of the incus, for the purpose of transmitting the vibrations of the membrane directly to that bone.

"3. Division of the incudo-stapedal articulation through a small triangular opening in the membrana tympani.

"4. Attachment of a flap from the posterior segment of the membrana tympani to the head of the stapes, the incus being either wanting or removed.

"5. Division of the incudo-stapedal articulation in cases of existing perforation of the membrana tympani, division of the stapedius muscle and of mucous folds or adhesions.

"6. Removal of the stapes itself."

Blake's conclusions were as follows: "Mobilization of the stapes, including stapedo-tenotomy and division of adhesions, are of value in cases the result of suppurative disease, where the mobility of the ossicle may be maintained either by occasional after-treatment or automatically, by making it the point of touch of an artificial membrane; and that the same procedure—surgical mobilization—is of comparatively little value in the chronic nonsuppurative disease of the middle ear, either when the attempt is made to secure also a permanent opening in the membrana tympani or to connect the stapes with the membrana tympani either by flap or cicatrix; and therefore of the surgical operations proposed for the improvement of hearing

and the relief of tinnitus in severe cases of chronic nonsuppurative disease of the middle ear, the disarciculation and removal of the stapes, although it seems the more heroic procedure, is one likely to be of more lasting benefit than the removal of the incus, or malleus and incus, or than merely tentative efforts at mobilization."

Dr. F. L. Jack read a paper at the same meeting of the American Otological Society on Remarkable Improvement in Hearing by Removal of the Stapes. Jack's investigations were carried on at the Massachusetts Charitable Eye and Ear Infirmary at the same time with those of Dr. Blake, but independently. Most of the cases he reported were patients suffering from a chronic suppurative inflammation of the middle ear, although some of the patients operated on had a chronic catarrhal otitis media. In the latter class of cases Jack found some improvement follow the operation of removal of the stapes, but his most brilliant results were obtained in the cases of chronic suppuration.

In the discussion that followed the reading of these papers, Roosa said that "two years ago, in Berlin, Professor Lucae, who has probably performed more operations on the ossicles than any other, told him that in nonsuppurative inflammation of the middle ear he had abandoned the operation of removal of the ossicles, as so many cases were made worse and it was so difficult to make a prognosis."

Blake, subsequent to the reading of his paper before the American Otological Society, published several papers in the Archives of Otology, in which he has reported his results in cases of removal of the stapes; and in vol. xxii, No. 4, 1893, he sums up as follows: "The operation of the removal of the stapes does not answer the purpose which might be hoped from it in cases of chronic nonsuppurative disease of the middle ear. In all the cases of nonsuppurative disease in which the stapes was extracted entire the hearing was definitely and practically improved in one only." Blake obtained better results in some of the suppurative cases, but says that "it does not at all follow that the same, or at least sufficiently satisfactory results, could not have been obtained by the minor operations effecting a mobilization of the stapes or of the ossicular chain as a whole, and consequently maintaining that mobile condition by artificial means."

My own observations include a number of cases operated on, most of them being cases of excision of the drumhead and malleus, or drumhead, malleus, and incus, leaving the stapes in situ.

My results agree with those of Blake, that in patients suffering with chronic nonsuppurative disease, the operation of stapedectomy is not advisable. We are too apt in this class of cases to find the foot plate of the stapes united by bony ankylosis, and when trying to extract the stapes we simply break off the crura.

Bezold has reported a case of removal of the stapes in the disease of the middle ear, either when the attempt is made to secure also a permanent opening in the membrana tympani or to connect the stapes with the membrana tympani either by flap or cicatrix; and therefore of the surgical operations proposed for the improvement of hearing was done under cocaine, and was not painful. At the

moment of removal the patient sank on the other side with a sigh and became pale. Excessive giddiness lasted three days. Bezold concludes by saying that "it seems important to publish this case as soon as possible, to warn others against unfavorable results."

In excision of the drumhead and of one or more of the ossicles, I have had fairly satisfactory results in only four cases. In these, the hearing for the voice was considerably improved in two cases, and but slightly improved in two cases.

I can not agree with those surgeons who assert that the operation of removal of the ossicles, even if it is not productive of benefit, will at least not make matters worse, for I have in mind one case in which I operated, and which seemed to be an ideal case for such an operation, the maleus and incus being bound down by adhesions. Not only was there no improvement in the hearing to speak of, but after the operation a distressing tinnitus persisted.

I have under observation a neurasthenic patient who had the malleus, incus, and entire membrana tympani removed by a surgeon in another city, and who has been under my care since then. She was told that the hearing would not be made any worse by the operation, even if no improvement followed. Such was not the case, for she had a severe otitis media as the result of the operation, and the hearing has been decidedly worse since then. Dr. B. A. Randall, at a meeting of the American Otological Society in 1892, reported a case where suppuration, mastoid empyema, and burrowing abscess of the neck followed excision of the membrane and malleus for catarrhal deafness.

Others have been reported where unfavorable results have followed the operation, so that we should bear these cases in mind when advising a patient as to the propriety of removal of the ossicles.

In the light of my own experience, and in that of others both here and abroad, I think that we should not resort to excision of the membrana tympani and ossicles in cases of chronic dry catarrh until we have exhausted all other methods of treatment at our command. Before deciding as to whether removal of one or more ossicles is advisable in a certain case, we should perform under cocaine what Blake has called an "exploratory tympanotomy." By making an incision in the drumhead and opening the tympanic cavity, we can note as to whether this operation increases the hearing distance, and the effect, if any, on the tinnitus or possible vertigo. We can then apply cocaine to the middle ear, and examine more carefully as to whether the ossicles are bound down by adhesions. These adhesions can then be divided as well as the tensor tympani and the results observed, so that we can decide more clearly and with better judgment as to the advisability of a further operation-viz., removal of the membrana tympani and of one or more ossicles.

In some cases, however, it will be necessary to give an anæsthetic before doing an "exploratory tympanotomy."

Howard University, Washington.—The annual commencement exercises of the medical, dental, and pharmaceutical departments were held on Wednesday evening, the 11th inst.

# THE DOCTRINE OF SIGNATURES, AND SOME OF ITS MODERN ASPECTS.\*

WITH A REFERENCE TO DR. WILLIAM A. HAMMOND.

By J. S. LEONHARDT, M. D., LINCOLN, NEB.

THE sixteenth century of our era marks a notable and important epoch in the evolution of human progress. Human thought, that had groped about in the weary hours of a mental night over a thousand years long, now rejoiced in the full dawn of an intellectual day. Great schools of learning at Antwerp, Venice, Rome, Bokhara, and elsewhere were reviving the spirit of the Augustan age. In striking contrast with this enthusiastic restoration of literature, art, and most of the sciences, stands the art of healing; medicine did not seem to have any part in the general resurrection. Aside from Linacre in England, Vesalius in Belgium, Falloppius and Eustachius in Italy, Paré in France, and Servetus in Spain, each surrounded by an insignificant number of disciples, medicine had not yet emerged from the cell and keep of the priest and magician. A strange and tenacious fancy that had existed since the twilight of history was now in the high noon of its popularity. I allude to the doctrine of signatures, which completely dominated the medical thought of the day and which was most ardently promulgated and cleverly defended by Paracelsus, Crollius, Porta, and Böhme, who first raised it to the dignity of a theory.

The doctrine of signatures embraced two departments -the celestial and the terrestrial. Ancient Egyptian mythology, with its seven mystical cows, and the anthropomorphic ideas of the latter-day Greeks, fitted conveniently into the then prevalent notion of correspondences and similars. The gamut of Greek deities was accordingly made the connecting link between astrology and alchemy by confirming the existence of a double relationship between the planets of the same names and the metals. Amulets of pure gold, usually of a triangular shape, stamped with astrologic and hermetic characters, were worn suspended from the neck in order to protect the wearer from the evil influences of subtile poisons or malignant spirits. The talmudic and cabalistic Jews wore phylacteries in the same manner and for the same purposes. The ancient Egyptians made a similar use of a cruciform emblem, the sacred Q (tau) and a species of scarabæus, emblematic of immortality. Even the great Pericles wore his amulet thus. The anodyne necklace of Dr. Chamberlayne, in such good repute among English mothers and nurses during the

<sup>\*</sup>Those interested in a further examination of this most unique theory, which in its day amounted to almost a philosophy, may consult with profit the following works: Paris, Pharmacologia, New York, 1824; Dublin University Magazine, vols. Ii and Ixviii; Hermann Kopp, Die Alchemie, Heidelberg, 1886; Liebig, Handwörterlanch der Chemie, Braunschweig, 1842; Hermann Kopp, Geschichte der Chemie, Heidelberg, 1844; Ennemoser, History of Magie, London, 1854; Wilkinson, The Ancient Egaptians, New York, 1854; Knight, Ancient Let and Mythology, New York, 1876; Jennings, Rites and Mysteries of the Rosicrucians, London, 1887; Draper, Intellectual Development of Europe, New York, 1876; Proceedings of the Society for Psychical Research, London, etc.

April 14, 1894.]

sixteenth century, was an expression of the same idea. The Bedouin Arab of to-day still wears a metallic charm, while the poor Philippine Islander contents himself with the less attractive but more potent bean of Ignatius. Sometimes these periapts, with their mystical sigils, were steeped in wine, which was then drank-a practice that still survives in the lee-penny of Scotland. Upon special occasions the Hebrew or Greek name of the Deity, Adonai or Tetragrammaton, embellished with triangles and compound comminuted crosses-symbols of truth and Godwere written on pancakes and swallowed for the relief of persons suffering from unruly spirits. This practice still obtains in a modified form among the nomadic Tartars of Asiatic steppes, who, for the purpose of making their prayers more effective, write them on slates, wash them off, and drink the dirty water. A bridegroom in the middle ages, if at all advanced in the education of his time, would not think of repairing to his nuptial couch without wearing his consecrated silver ring, stamped with esoteric figures fitting such an auspicious event. A similar astrologic observance attended the marriage of the ancient Aztec. And to-day every one entitled to wear a shell from Joppa has heard of the wonders Solomon performed with his cabalistic ring. The knight who entered the lists or undertook a perilous journey was doomed in advance to defeat or chagrin unless his steed wore a bridle made of lion's skin, which gave his horse both strength and speed. Scorpions had no terror for him who wore upon his person the sign of Scorpio.

Their earthly materia medica contained every known and accessible object in the three great kingdoms of Nature. They believed that all plants, minerals, and animals, or parts thereof, that were designed for the use of man indicated their particular application by some external or internal peculiarity either of form, color, mark, or resemblance; that these objective qualities corresponded to definite parts of the body, suggested prominent clinical features of some disease, or bore the impression of some alchemistic or astrologic symbol or sign which mystically governed the same. They taught that Nature had so marked these things that man by his reason might determine their several uses to him. They affirmed that this object could not have been effected more perfectly by any other means-"not even by speech, since no language is universal." Those whose education enabled them to read these signatures of Nature and interpret the occult relation existing between the objects that bore them and the cure of disease were dubbed "Nature's principal secretaries." Boyle, the great Earl of Cork, said: "Chymists observe in the Book of Nature that those simples that wear the figure or resemblance (by them termed signatures) of a distempered part are medicinally for that part of that infirmity whose signature they bear." Any substance that could not be so read and translated was pronounced inert or noxious.

Turmeric, Indian saffron, on account of its yellow color, was said to be a specific in jaundice. The capsule of Papaver somniferum was regarded as specially designed for diseases of the head. Agaricus, a cryptogamous fungus, because of its bladderlike pileus, was supposed to be good

for bladder diseases. Cassia fistula, an Oriental tree bearing yellow flowers and legumes about two feet long filled with seeds imbedded in a black pulp, was used in intestinal diseases. Aristolochia, birthwort, probably on account of its indicative etymology, was the remedy for uterine ailments and disorders attending parturition. The seeds of the common gray millet, Lithospermum officinale, on account of their pearly whiteness and marblelike hardness, were supposed to be good in calculous affections. It was asserted and for a long time believed that when these seeds were placed in vinegar they would effervesce, thus establishing their calcareous nature. All spotted or blistered vegetables were considered good for the lungs, since these organs have a mottled and blisterlike appearance. Euphrasia, because of the dazzling brightness of its little white flowers, and for the extra reason that its corolla bears a black spot like the pupil of the eye, was a sovereign remedy in diseases of the eye. Crocus sativus, the famous zahafaran of the Arabs and carcom of the Jews, because of its yellow blossoms and golden tincture, was the remedy, above all others, for forcing out variolous pustules and curing biliousness. A tea made of the stinging nettle, Urtica dioica, was prescribed in urticaria and doubtless other forms of pruritus. Thus also the petals of the "blood-red rose," as well as hematites from Ethiopia and Arabia, were employed in blood diseases. Ginseng, a remedy still very popular in Tartary and China, was regarded as of such value in all forms of mental and physical debility that the respect paid it almost amounted to veneration. In addition to its aphrodisiac power, it was looked upon as a sure eradicator of old age, a drug that contained the "pure spirit of immortality." So rare and valuable was this remedy in these countries in the olden times that it was used only on patients of quality, and then sold for its weight in gold. Strange to say, it was used for the same purposes among the North American Indians. The Iroquois name for it means "a child," and jin-seng in Chinese means "resemblance to a man." Mandrake, when forked, on account of its fanciful likeness to the body, and, when straight, to the phallus, was used as a sexual stimulant and against the curse of barrenness from remotest antiquity. It was a common ingredient of love philters and often invoked in amorous incantations. Students of archæology will recall the effect of Reuben's mandrakes on Rachel.\* Leaves of the kidneywort, from their resemblance to a kidney, explain their use in renal complaints. The modest forget-me-not, because its spike looks something like the end of a scorpion's tail, was considered curative in the sting of that animal. For the same reason the fungus known as Jew's ear, in size and shape much like a human ear, was used in diseases of the ear. All plants bearing stellate flowers were in special demand. Lapis ætites, a hollow ferruginous stone containing a free nucleus. was used since the days of Pliny and Dioscorides; suspended above the uterus, it prevented abortion; suspended beneath it, it facilitated labor. It was supposed that the eagle placed these stones among its eggs when hatching to prevent their decaying. In addition to vegetable remedies in hepatic diseases, they used wolf's liver, or the liver of an ass pounded in honey. Zwelfer extolled the virtue of amulets made of compressed toads as prophylactic against carbuncles, buboes, and the plague. Van Helmont, the eminent Belgian chemist, suffering from a severe fright caused by a toad, did not trust to toad lozenges, but cured himself by taking powdered viper mixed with molasses. Dried deer tears were used in their battle against hysteria, in the treatment of which some of our homeopathic friends of to-day use lacrima filia. Consumptives and asthmatics were treated with prepared lung of fox or wolf. Anæmia yielded to blood of bat, rat, or rhinoceros. We once used sanguis bovinus exsiccatus! Boyle was "radically" cured of an obstinate epistaxis by applying to the skin until it got warm the moss of a dead man's skull. By a more or less logical extension of their system, they were able to displace the legitimate function of cats by substituting their images made of lead. To keep the rot from affecting their sheepfolds, they set up in the pastures artificial sheep skillfully molded in clay. Flies would light on no man who wore any charm of steel. The duelist, wounded by the sword of his adversary, anointed the weapon of his foe with a magic salve instead of applying the unguent to his own perforations. Moles on the face disappeared under the touch of a dead man's hand if it was allowed to remain long enough to get warm

To supply their materia medica all Nature was laid under tribute, from the majestic iceberg to the somber gravevard. Their pharmacies must have exceeded in horror the forbidden chamber of the celebrated Bluebeard, and their "medicine making" during many a Walpurgis night doubtless surpassed in weirdness the famous witches scene in Macbeth. Human bones, fat, blood mixed with triturated carrion, flies, and attar of roses; every organ and every secretion and excretion; different parts of apes, lions, dogs, scorpions, eels, spiders, serpents-in fact, every indigenous animal and many that were foreign-all these things, singly and in endless combinations, were their weapons against disease. And this vile stuff was used solely because of a mystic relation supposed to exist between it and disease in its various manifestations. And this incongruous belief not only permeated every phase of their social fabric, but actually was the pet of regal patronage and everywhere the curled darling of prosperity.

That Hahnemann obtained his ideas of homeopathy from the residuary of the ancient estate of alchemy and the doctrine of signatures can hardly be questioned in the light of history. His theory of infinitesimals was used long before him by alchemists, who taught that the least conceivable quantity of their royal elixirs was sufficient to transmute the baser metals into silver and gold. Many of the nasty things then used are still employed by homeopathists, and, unless Hahnemann was the victim of heterophemy, similia clearly betrays its lowly origin in the doctrine of signatures. In evidence of this may be cited such remedies as crotalus horridus, lachesis, bufo, carbunculus, fel suillum, fel tarantula, pyogen; ovi membrani, to induce menstruation always at the full of the moon; loimine, pest virus; sal cerebri, salt secreted from the scalp of a gentle-

man; seriaca Barlowii, made from a silk handkerchief that had been swallowed by a cow, in whose stomach it was found after three years, during which time she never had a calf (inference, ad libitum); verruca menstrua,\* menstrual blood from a woman who had warts; and so on till nausea ensues. Quite recently I noticed in a medical periodical that plants bearing blue flowers were brain sedatives; those having red flowers excited nerve action, increased congestion, and acted specifically on the hæmatopoietic system; and those having yellow flowers were particularly good in liver troubles.†

During the last few years it has been quite a popular medical fad to administer the juice of certain animal organs for the relief or cure of disease affecting similar organs in the human being. This idea is nothing more and nothing less, in my opinion, than the same old malady of signatures and correspondences in a modern exacerbation. Is it not a strange irony of history to see the sepulchered vagaries of a dead past again rehabilitated by members of enlightened communities in this brilliant age? The doctrine of signatures in its entirety is so completely hidden under the dust and grime of centuries that it is difficult now to even collate its literature; yet the spirit that gave this grotesque empiricism a name in history not only survives in our modern museums, schools of medicine, and credulous laymen, but, when animated by the genius of Paracelsus, defiantly flaunts its offal-stained banner in the very peristyles of our scientific schools. The revival of ancient faiths and mysticism, together with a tacit acceptance of mediæval pseudo-science and philosophy, is a remarkable part of present history. Belief in mascots, charms, magic rings, ghosts, the power to communicate with those who have returned to unconscious dust, prophecy, incantations, philters, elixirs of life, animal magnetism, stellar influences, lucky days, the doctrine of signatures-all these and a hundred other inanities show an extraordinary trend of thought in the closing years of such a century as this has

The origin of Dr. Hammond's animal-extract idea, therefore, it seems to me, is not enveloped in the impenetrable darkness one would infer from reading his contributions on the subject. The pregnant past has brought forth other men who practiced the theory of that one German physician of whom Dr. Hammond remembers reading about some forty years ago, whatever length of time that may mean. Dr. Hammond is afflicted with philosophic atavism, the pathognomonic symptoms of which are none the less conspicuous for his having masked them in terms of modern scholasticism or verbal neoplasms of his own. His dexterous defense of these antiquated notions, while supporting his pet selection of them-the truth of which he sought to establish by means of physical demonstrations-and his evasive answers to my criticisms, compels a final notice of his diatribe in the New York Medical Journal of November 18, 1893.

<sup>\*</sup> Swan. A Catalogue of High Potencies, New York.

<sup>†</sup> Medical Review, St. Louis, quoting The Medical World, Philadelphia.

As to the length of time he had used the sphygmographs of Marey and Pond, he admits that he was a little extravagant with the truth, but adds, with much indifference, "But what does it matter?" and commends to my consideration an alleged legal maxim. Physiological research would have but little scientific value conducted by one thus careless of the element of time; this may not have been true when Dr. Hammond filled the chair of physiology in the medical department of the University of Maryland in 1860, but it is now. While I am digesting the Latin quotation assigned me, I would call his attention to the fact that common law recognizes such a thing as gross carelessness and criminal ignorance. I commend to his prayerful attention the interview between Pantagruel and the Limosin.\*

In the sphygmogram taken from Brondel (an author of whom I know about as little as Dr. Hammond does of Dr. Dudgeon) we have another delightful instance of his "lumping-off" process. The reader is left to guess at the age and physical condition of the subject preceding the hypodermic injection of an exceedingly liberal dose of pilocarpine. We infer that the pure alkaloid was used, but he may have meant any one of its six or seven salts. We are also wholly in the dark as to the object of that injection, whether therapeutic or experimental, and as to the time element in the case. If the tracing was taken soon after the injection was given, at the time when flushing of the skin, fullness of the head, and redness of the face and neck occur, then it was taken during the stage of the drug's primary action, when it really does stimulate the heart + Add to this slight stimulation of the heart a decided lessening of the peripheral resistance, and you have in the primary physiological effect of pilocarpus all the requirements of a first class, quickly-acting cardiac stimulant. If the drug were never urged beyond this initial effect, we should have a heart tonic that would compare very favorably with atropine and trinitrin. Now, then, if the instrument with which the Brondel tracings were made moved the recording surface with equal speed in both instances, the most casual examination will show that the heart beat about one tenth more rapidly and the pulse waves were about twice as ample after the use of pilocarpine. If time and distance amount to anything in matters of this kind, and the primary effect of pilocarpus is taken into account, the cause of the "excessive" verticality of the second tracing as compared with the first becomes obvious, especially when made with an instrument of the Marey type. As I have said in a former article, the recording needle in this class of sphygmographs always describes the arc of a circle whose radius is equal to the length of the lever producing it. In most of these instruments the slide moves toward the center of this circle. Therefore, if the slide moves at all, the arc traced will depart from its normal curve in a degree determined entirely by the speed of the slide and the time required for the lever to reach its greatest altitude. He who uses a Dudgeon sphygmograph does not have to contend with

these variations, because the recording needle in this instrument is made to move in a perpendicular and straight line. Dr. Hammond asserts that nothing is more absurd than to compare the results obtained by one sphygmograph with those obtained by another. Dr. Baumgarten does not seem to think so.\* But "What does it matter?" the valiant champion of cardine will doubtless reply; "in regard to the sphygmograph, I have never put much confidence in it." Dr. Hammond seems to forget that in a former paper he sought to confirm his statements regarding the heart-tonic properties of cardine by means of this very instrument, and said it did very clearly. Now that it has ceased to answer his purpose, he quotes it as being untrustworthy.

In regard to my own sphygmogram, of which Dr. Hammond speaks in an exceedingly facetious manner, he is more amusing than correct. He should remember, if possible, that when the subject breathes regularly during the taking of a sphygmogram the tracing will show a respiratory curve, if the instrument used is sensitive enough to be influenced by respiration. The depressed portion of the pulse waves in my tracing corresponds with the act of inspiration. If he will measure and compare the several curves he will find that the variation is in strict accord with that of a typically normal tracing, in which the up strokes are nearer together in inspiration by about 0.06 second. Another reference to the monumental work on physiology by Landois and Stirling + will discover two sphygmograms—one made by Dudgeon's and the other by Marey's sphygmograph—both of normal pulses under equal pressures. My personal tracing is as nearly like the one made by Dudgeon's instrument as can be; the other, taken with Marey's instrument and also termed normal, does not bear the slightest resemblance to the alleged normal sphygmogram in Dr. Hammond's first article on cardine. As to the comparative ability of the two instruments to duplicate what actually occurs in the circulation, let the reader compare the two tracings with the hæmautographic curve shown in the same work; let him also notice that the learned authors still continue to use Dudgeon's instrument for the elucidation of physiological events, even if Broadbent does not trust it. My heart is not affected with any of the pathological conditions mentioned by Dr. Hammond, since there is no evidence of irritability, intermittency, excessively low or high tension, or abnormal speed, one or more of which conditions are always present in any form of cardiac disease. I call my personal tracing normal, and again challenge Dr. Hammond to prove the contrary by any rule of sphygmography or process of reasoning whatever.

The reader of Dr. Hammond's articles on animal extracts will have noticed another fact that concerns cardine just a little; it is in the nature of a "control experiment," and proves cerebrine more powerfully cardiac than cardine itself. In from five to ten minutes, or even less, after an injection of five minims of cerebrine, the pulse became fuller and stronger, and increased about twenty beats to the minute. So potent is this brain extract that a single five-minim injection will project its influence through a

<sup>\*</sup> The Works of Rabelais, Book II, chap. vi.

<sup>†</sup> Potter. Materia Medica, Pharmacy, and Therapeutics, fourth edition, Philadelphia, p. 319.

<sup>\*</sup> Reference Handbook of the Medical Sciences, vol. vi, p. 87.

<sup>+</sup> Landois and Stirling. A Text-book of Physiology, pp. 119, 120.

space of several days. In about ten minutes after a fiveminim injection of cardine the pulse increased seventeen beats to the minute, while the dynamic inertia of the extract began to lessen in about eight hours. Another peculiarity must have arrested the reader's attention: I refer to Dr. Hammond's overweening modesty. His reference to "sciolists who rush in with heavy foot where angels should tread lightly" is a delicately worded warning with a commercial margin to all who might attempt to manufacture these extracts. His yielding priority of the idea to an unknown German physician, after remarking that the two systems (?) do not admit of comparison, is self-sacrifice personified. For him to say that the isolated observations made in the last two or three years by German and French collaborators, while in accord, to some extent, with his own, lacked system and were barren of definite results, is deliciously exclusive.

Since Dr. Hammond has been kind enough to diagnosticate my multiform affliction, it would be ungrateful in me not to offer some recognition of his service. If Dr. Hammond is "a victim of heterophemy," he is also afflicted with word-blindness; both of these symptoms are regarded as significant indications of primary mental deterioration. I shall not be so cruel as to refer him to some specialist in mental diseases, but will simply ask him to review the treatment (with a view to its personal application) he advised in the case of a certain "literary gentleman of distinction, who spoke with a good deal of volubility, but constantly used the wrong expressions," who, when he wished to say that "he had visited Europe for the benefit of his health," said, "I went to Elope for the bequest of my hedge." \*

# A CONSERVATIVE TREATMENT FOR GONORRHŒA.

WITH REPORT OF TWENTY CASES.

By H. ELLIOTT BATES, M. D.,

POUGHKEEP-IE, N. Y.

The ancient and time honored statement that the more numerous the agents and methods put forward for the treatment of a diseased condition, the greater the probability that that condition is imperfectly understood and imperfectly treated, seems to apply with special force to that inflammation of the urethral mucous membrane known as gonorrhea.

Drug after drug has been said to be a specific. Different methods of treatment—abortive, methodical, expectant, by irrigation, injection, electricity, and so on through the entire range of therapeutic resource—have been discovered, published in the various journals, received a trial, and given more or less satisfaction or disappointment. Meanwhile the victim of this well-intended experimentation goes as often to the drug store or charlatan as to the regular practitioner.

The writer of this article would feel some hesitation in adding to the subject were it not for the fact that, after

\* Hammond. Diseases of the Nervous System, New York, 1890, pp. 180, 181.

what he believes to have been a fair trial, results have been attained which will justify the presentation of the method of treatment, conservative as it may claim to be, before the profession.

The twenty cases here reported have not been selected, but taken as they were put down upon the case-book.

The conservative treatment herein presented is based upon the indications and principles of treatment of any inflamed mucous membrane.

Catarrhal inflammation of mucous membranes may be acute, subacute, or chronic.

Congestion, dryness of the surface, subsequent mucopurulent or purulent discharge, desquamation of superficial epithelial cells, mucoid discharge, and recovery of the normal tone, or passage into a chronic state, is the clinical history of such conditions, be the inflammation that of bronchi, stomach, or urethra.

Simple non-specific urethritis, like bronchitis, runs a short course, with mild symptoms and brief duration.

The specific form of urethritis is contagious, but resembles in its course, symptoms, and results the simple form, with this difference, that it is virulent, obstinate, and prone to leave sequelæ. Nevertheless, if left severely alone, it will often result in complete recovery.

It is true that the past history of many strictures contains an attack of gonorrhœa which is said to have caused the stricture, but the writer is forced to believe from his experience that the stricture is often due to the treatment given the gonorrhœa, particularly to the strong injections, rather than to the influence of the disease itself. For the writer has yet to see a case of stricture which followed a simple, uncomplicated attack of specific urethritis unless strong injections have been employed.

That a complicated attack may and does produce stricture, independent of powerful injections, is proved by Case III of the table in this paper.

We do not seek to abort an attack of bronchitis any more than we attempt to check secretion in its primary stage by strong astringents. Why should we seek to do it in gonorrhea?

In the experience of the writer specific urethritis has a stage of incubation averaging four days; an acute stage, averaging fourteen or sixteen days; and a subacute stage, averaging fifteen days, ending in recovery after a total average duration of thirty-one days.

The indications for treatment are those for the inflammation of any mucous membrane:

- To relieve irritation, minimize the congestion, and subdue the inflammation.
- \* 2. To allow the acute stage to subside and correct the tendency to catarrhal flux by mild astringents.
- To prevent development of the chronic stage and sequelæ by removing any causes operating to produce them.

To attempt to abort the disease seems unscientific, irrational, and contrary to indications or experience.

To check or stop purulent discharge is impossible. Agents are employed of a strength sufficient to destroy not only pathological products but normal tissue as well.

If left to its natural course, the inflammation not added to, the purulent discharge changes to a muco-purulent or mucous oozing.

Then, and not until then, may injections be expected to do only good, and these should be extremely mild.

Then, if the discharge still lingers, it is due to patches of diseased tissue which injections will not and can not reach, but which the steel sound will soon dissipate, with prompt improvement.

Agents like oil of sandalwood, copaiba, or cubebs irritate the stomach and kidneys and are plainly contraindicated. The writer has never employed them. The experience gained by him while in the veneral department of Chambers Street Hospital, where an almost infinite variety of cases receive corresponding treatment, led him to adopt the following method of treatment, the results of which he believes will compare favorably with any yet given:

The patient is ordered to procure and wear a suspensory bandage until discharged cured. Indulgence in tea, coffee, stimulants, suggestive conversation, literature, pictures, and the like, as well as any active exercise, is prohibited. The diet is simple and curtailed, the bowels are kept open, and milk with Vichy water taken ad libitum, also Londonderry lithia water. Unsweetened lemonade and the following mixture, to render the urine alkaline, limit the ardor urine, and prevent chordee, is all the treatment given in the acute stage:

Ŗ.	Potassii acetatis, { Potassii citratis, }	i.	
	Potassii citratis,	J,	
	Sodii bromidi 3	i;	
	Ext. hyoseyami fl 3 s	ss.;	
	Spts. ætheris nit 3	ss.;	
	Syr. aurantiiq. s. ad 3	j. M.	

Of this two teaspoonfuls are taken several times through the day and evening.

The glans penis is wrapped in cotton and the foreskin drawn forward over it.

The bromide of sodium, with now and then a supposi- nal, September 2, 1893.

tory of opium, aconite, and belladonna, usually will prevent severe chordee.

This treatment is maintained until the discharge changes from thick, yellow, and purulent to thin, bluish white or colorless, and without traces of pus or blood.

Up to this time the patient is not allowed to use any injection whatever.

Second Stage.—For three days, morning and evening, the patient injects a small quantity of a solution of hydrogen peroxide diluted with water. At the end of three days the following is given:

Ŗ	Zinc sulphate gr. xij;
	Boric acid 3 ss.;
	Colorless hydrastis 3 vj;
	Rose-water ad \( \frac{7}{2} \) vj. M.

To be used morning and evening.

In the majority of cases no further treatment is required.

If the discharge lingers, the sound is passed several times, and the results are entirely satisfactory.

The collected twenty cases will show some quite satisfactory results.

- 1. No stricture ever followed treatment,
- 2. Average duration, thirty-one days.
- 3. Complications were seldom met with.
- 4. Chordee occurred in but four cases; never severe.
- 5. The cases of simple urethritis received no injections.
- Epididymitis occurred in two cases. That it did not prove more frequent is probably due to the early use of the suspensory bandage.
- 7. The same may be said in regard to the enlargement of the inguinal glands.
- 8. The sound was employed in all cases in which the attack was the second, with prompt success.
  - 9. Gonococci were present in all severe cases.
  - 10. Gonococci were absent in all mild cases.

Case III was reported in the New York Medical Journal, September 2, 1893.

THE

# NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by D. Appleton & Co. Edited by FRANK P. FOSTER, M. D.

### NEW YORK, SATURDAY, APRIL 14, 1894.

#### GUAIACOL.

In a recent discussion before a society of one of our larger American cities some twenty experiments with guaiacol in phthisis, pneumonia, tertian ague, typhoid fever, rheumatic fever, and influenza were reported. The dose was about thirty drops, rubbed upon the skin. In every case the temperature had come down from 104° F. or thereabouts to the neighbor hood of 100° within a few hours after the application, and remained down for several hours. In every case, as nearly as the writer can remember the report, there was profuse sweating as the temperature descended. The trouble with the method, however, was that most, if not all, the patients suffered from severe depression of the bodily powers during the fall of temperature, in many cases extremely disquieting to the sufferer. During the discussion of the report other experiences from private practice were related in which the prostration following similar use of the drug had been extremely alarming.

The president of the society being of an amiable disposition, and, although a specialist, not one of those repressive anxiousfor strictly-parliamentary-limitation autocrats who make modern society meetings often so intolerably dry to the seeker after clinical aid, the discussion took in the whole subject of temperature reduction in fever. The prevailing sentiment of the meeting seemed to be that reasonable temperatures, say not higher than 103°, had in most cases very little disturbing effect either on the patient's comfort or on the outcome of the disease, and could be sufficiently controlled by absolutely safe remedies, such as diuretics, aperients, and tepid-water spongings. Such elevations of temperature correspond to that overproduction of heat which results from the natural efforts of the tissues to destroy morbific material-the law of life being that all increase of destructive tissue-change is accompanied by increase of heat. So long as this material continues to irritate the tissues the fever must continue, its issue in most cases being in the triumph of the tissues. To check this natural process forcibly without removing the offending matter is an unwise and injurious proceeding on the part of the therapeutist. The only sensible method is to remove the offending matter from the body or, if this can not be done, to strengthen the tissues in their struggle, avoiding all depressing drugs.

In hyperpyrexia, however, where the temperature stays above 104° for days, hurting the heart-muscle, or where the nervous system of the patient is greatly disturbed and the secretions and excretions are checked, we have to do, not with

the natural heat-production of the internal contest, but probably with derangement by the hot blood of the nerve centers which regulate the production of heat and its escape from the body. In these cases active interference is demanded. Cool sponging or bathing, and in extreme cases the free use of icewater and ice to the surface of the body, are to be preferred to the use of depressing drugs. Occasionally the modern febricides may be used for temporary benefit. Here, along with acetanilide and antipyrine, guaiacol may be used, but with great caution until the patient's reaction to them is ascertained. Guaiacol might be tried in smaller doses than those reportedsay, less than thirty drops. The remedy which makes the patient stronger and more comfortable, improving the secretions and excretions, and giving sleep, is in every case to be preferred to those which, while they lower the temperature, cause prostration, or at least fail to add to the general well-being of the patient. In family practice, especially, all drugs which might by their depressing effects alarm the patient's friends must, as a rule, be avoided.

Morphine was mentioned as a valuable temperature-reducer when the nervous system is fagged out. Careful, regular feeding is, of course, essential to the patient's recovery

#### RELAPSES OF TYPHOID FEVER.

DR. HUGH M. STEWART, of Guy's Hospital, London, contributes an article on this subject to the March number of the Practitioner, founded in great part on the clinical histories of fifty cases observed in the hospital. He thinks that so-called relapses are genuine second attacks; that they are due to re-infection (infection in a fresh part of the intestine, always at a lower situation and usually in the large intestine) from the patient's own lesions; that constipation is an important predisposing cause of relapse; that relapses occur at a certain definite period-on the average, after an apyretic interval of a little less than six days for first relapses and of a little over thirteen days for second relapses; that relapses are rarely fatal; and that they heighten the patient's immunity from subsequent attacks. While, as has been said, he regards constipation as an important predisposing cause of relapses, he intimates that it ought not on that account to be treated, for the reasons that the prognosis in cases of relapse is good, that the occurrence of a relapse probably confers a higher degree of immunity than a single primary attack, and that treatment of constipation may excite a dangerous degree of peristalsis. Intestinal perforation is far less common in a relapse than in an original attack, partly because the infection is less profound, owing to the partial immunity occasioned by the initial attack, and partly because the large intestine, where the lesions of the relapse are prone to be found, is thicker-walled than the small intestine. Relapses run their course more rapidly than original attacks, as regards both lesions and symptoms, and this fact gives rise to the false appearance of all the lesions being of the same duration at the necropsy.

#### MINOR PARAGRAPHS.

#### SOLANUM CAROLINENSE.

This southern plant, popularly known as poison potato, ground-potato, horse-nettle, and tread-soft, has been made the subject of study by Mr. J. U. Lloyd, who gives an account of it in the April number of the American Journal of Pharmacy. It appears that the plant is reputed poisonous, perhaps because animals of all kinds refuse to eat it; that the negroes of the South have long used it as a domestic remedy for convulsions and as an aphrodisiac; and that it was brought to the attention of the medical profession in 1889 by Dr. J. L. Napier, of Blenheim, S. C., in a paper read before the Medical Society of South Carolina. Dr. Napier found the root and the berries efficient in checking convulsive attacks, especially those connected with the menstrual period, also in epilepsy, puerperal and hysterical convulsions, and traumatic tetanus. He used a whisky-andwater preparation, but its strength is not specified by Mr. Lloyd. Dr. Napier states that the plant is a very active diuretic, besides being antispasmodic and anodyne. A syrup made from it has a local reputation in Georgia as a remedy for cough. Mr. Lloyd has obtained from the root an alkaloid to which he 'gives the name of solnine, to distinguish it from solanine, with which he thinks it is not identical, so far as can be inferred from what is now known, especially from the crystallization of solnine, of which an excellent illustration accompanies the article. It is to be hoped that therapeutical experiments with this new alkaloid will soon lead to more precise information as to its medicinal properties than we now possess.

#### TERATOLOGIA.

Tms is the title of a quarterly publication, the work of Dr. J. W. Ballantyne, of Edinburgh, devoted to teratology and antenatal pathology. The first number, dated April, 1894, has reached us. It contains considerable matter of scientific and historical interest.

#### AMERICAN ACHIEVEMENTS IN SURGERY.

In the April number of the Forum Dr. George F. Shrady writes most graphically of the leading achievements of American surgeons. The community needs to be reminded once in a while of what natives have done creditably.

# SOME FOREIGN IMPRESSIONS OF THE CONDITIONS OF MEDICAL PRACTICE IN AMERICA.

During the last week two things have come to our knowledge that show curious phases of the notion largely entertained by Europeans that they can come to the United States and enforce among us such regulations as they see fit or abrogate at their pleasure those that we have established. The first is a letter written by a megalocephalic Berlin doctor to the dean of one of our city medical schools in which he says: "Kindly let me know whether the Diploma of Dr. of Medicine of a German University or the certificate as Physician granted by the Government of one of the German States, entitles to the Practice of Medicine (as a registered Physician) in the State of New York. Although I think that it is a matter of course, that German Diplomas are registered there as medical qualifications, because German Doctors are, as you will know, the best in the world and as medical education in the United States of America is not recognized anywhere in Germany, I ask this question anyway to prove that German Diplomas are worshiped and recognised everywhere in the U.S. of America." The other thing was the retort made by one Dobroczynski, on the occa-

sion of his being convicted for the second time of practicing dentistry illegally, to the judge, who had reminded him of his previous conviction. It was this: "In the old country, when a man pays a fine for such an offense as this the fine pays his license, and he can go ahead. I thought it was the same in this country."

#### ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 10, 1894:

DISEASES.	Week end	ing Apr. 3.	Week ending Apr. 10.		
	Cases.	Deaths.	Cases.	Deaths.	
Typhus	0	0	0	0	
Typhoid fever	8	3	3	4	
Scarlet fever	158	15	143	20	
Cerebro-spinal meningitis	0	-0	0	()	
Measles	318	24	278	21	
Diphtheria	224	56	160	49	
Small-pox	33	5	10	7	

The American Medical Association.—Dr. H. A. Hare, of Philadelphia, and Dr. W. H. Washburn, Secretary, of No. 803 Grand Avenue, Milwaukee, request us to announce that the officers of the Section in Practice for the meeting of the association in San Francisco will be glad to receive the titles of any papers which gentlemen desire to read at that meeting. They add that a large number of papers have already been promised for the meeting by members of the profession on the Pacific slope, and that it is earnestly desired that an equal number of contributions should come from eastern portions of the country.

Newspaper Anatomy.—One of the city newspapers lately gave an account of an amputation "about half-way between the knee and the thigh."

The Middleton Goldsmith Lecture of the New York Pathological Society will be delivered by Professor William H. Welch, of Baltimore, on Saturday, April 28th, in the hall of the New York Academy of Medicine, on the subject of Mixed and Secondary Infections.

Changes of Address.—Dr. Edward B. Heckel, to No. 524 Penn Avenue, Pittsburgh, Pa.; Dr. Charles Schram, to No. 1074 Madison Avenue.

The Death of Dr. Charles Corey, of Brooklyn, is announced as having taken place on Wednesday, the 4th inst., somewhat suddenly, as the result of pneumonia. Dr. Corey was a graduate of the Medical Department of Dartmouth College, of the class of 1856, and was in the sixty-fourth year of his age. He was an alienist of considerable local renown.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 1 to April 7, 1804:

The following named officers are detailed to represent the Medical Department of the Army as delegates to the Association of Military Surgeons of the United States, to meet in Washington, May 1, 1894: Forwood, William H., Lieutenant Colonel and Deputy Surgeon General; O'Reilly, Robert M., Major and Surgeon; Corson, Joseph K., Major and Surgeon; Reed, Walter, Major and Surgeon; Phillips, John L., Captain and Assistant Surgeon; and Edie, G. L., Captain and Assistant Surgeon.

Carter, Edward C., Captain and Assistant Surgeon, will proceed at once to Fort Spokane, Washington, and report the commanding officer for temporary duty.

CLEARY, PETER J. A., Major and Surgeon, will be relieved from duty at Fort McPherson, Georgia, by the commanding officer of that post, on the receipt by him of this order, and will report in person to the commanding officer at Fort Custer, Montana for duty at that post.

HEIZMANN, CHARLES L., Major and Surgeon, is granted leave of absence for twenty-one days, to take effect on or about April 14, 1894.

KIEFFER, CHARLES F., First Lieutenant and Assistant Surgeon, having reported at Headquarters, Department of Dakota, is assigned to temporary duty at St. Paul, Minn., and will report to the Medical Director of the department for instructions.

MUNSON, EDWARD L., First Lieutenant and Assistant Surgeon, will proceed without delay to Camp Merritt, Montana, and report to the commanding officer for temporary duty at that post.

SNYDER, HENRY D., First Lieutenant and Assistant Surgeon, is relieved from duty at Fort Reno, Oklahoma Territory, and ordered to Fort Du Chesne, Utah, for duty at that post, relieving Robinson, Samuel Q., Captain and Assistant Surgeon. Captain Robinson, on being relieved by Lieutenant Snyder, will report in person to the commanding officer at Davids Island, New York, for duty at that post.

#### Society Meetings for the Coming Week:

Mondar, April 16th: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

Tuberay, April 17th: Medical Society of the State of California (first day—San José); New York Academy of Medicine (Section in General Medicine); New York Obstetrical Society (private); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Kings and Westchester, N. Y.; Baltimore Academy of Medicine.

Wednesday, April 18th: Medical Association of Georgia (first day—Atlanta); Medical Society of the State of California (second day); New York Academy of Medicine (Section in Public Health and Hygiene); Harlem Medical Association of the City of New York; Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society; Windham, Conn., County Medical Society (annual—Plainfield); Middlesex, Mass., South District Medical Society (annual, Waltham).

THURSDAY, April 19th: Medical Association of the State of Alabama (first day—Birmingham); Medical Association of Georgia (second day); Medical Society of the State of California (third day); New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Mass., Society for Medical Improvement (private); Tolland, Conn., County Medical Society (annual).

FRIDAY, April 20th: Medical Association of Georgia (third day); Medical Association of the State of Alabama (second day); New York Academy of Medicine (Section in Orthopædic Surgery); Baltimore Clinical Society; Chicago Gynæcological Society.

SATURDAY, April 21st: Medical Association of the State of Alabama (third day); Clinical Society of the New York Post-graduate Medical School and Hospital.

#### Answers to Correspondents:

No. 424.—Male nurses not drawn from a training school are employed at the Roosevelt Hospital, and all the large general hospitals have men as orderlies. By making early application in person you might obtain a temporary appointment.

# Proceedings of Societies.

#### NEW YORK ACADEMY OF MEDICINE.

Meeting of February 15, 1894.

The President, Dr. D. B. St. John Roosa, in the Chair.

Scurvy in Children.—Dr. W. P. NORTHEUP read a paper with this title. (To be published.)

Scorbutic Pseudo-paralysis.—Dr. Henry Ling Taylor read a paper on this subject. He said that this condition was a peculiar and prominent symptom of scurvy in children. The patient upon whose case the study was based had been brought to the author for some form of paralysis. The child, eleven months and a half old, had been fed exclusively upon a special brand of condensed milk. The first local symptom noticed had been weakness in sitting up, and then there had been absolute inability to hold the body erect. Tender swellings next appeared on the right thigh. The gums were spongy and one of the eyes was black. The patient had lost both appetite and flesh. At no time had the digestion failed or the bowels been out of order. The rectal temperature was 102.5° F. The skin was covered with a papular eruption. The breath was very fœtid. The patient made no attempt to move the legs. The knee reflexes were normal. Pressure elicited pain over the limbs and over the first and second lumbar vertebræ. The spine was rigid. There were no symptoms of rickets. Scorbutus was diagnosticated, and the patient was put upon the use of Pasteurized milk, orange juice, and beef juice. Improvement began at once. The only drug used was phosphate of sodium as a laxative. The cure was complete in a very short time. There was no doubt that condensed milk did considerable harm when employed exclusively as a diet for young children. The children of the rich were much more likely to have scorbutus than those of the lower classes, for the reason that in the lowly household the child was taken to the table and allowed to have whatever there was upon it, while in the wealthy family the baby was fed 'upon something prepared especially for it. When a child failed to sit up at a proper time, or when it had been sitting and then could not do so, an investigation should be made with scorbutus in mind.

It must be remembered that pseudo-paralyses were among the most striking symptoms of this disease and should be looked carefully into. The author thought from the pathological findings in Dr. Northrup's case that a toxicity of the blood might be assumed. It was also thought that some of the obscure cases of bowing of the spine might be scorbutic, and that it would be well to bear this in mind when examining for rhachitic paralyses.

Dr. FLOYD M. CRANDALL read letters on the subject from Dr. Louis Starr, of Philadelphia, Dr. Rotch, of Boston, and Dr. Forchheimer, of Cincinnati.

Dr. STARR had seen thirteen cases of scurvy in children. In the main, the symptoms were like those described, with the exception that the mouth condition was not present unless there were teeth to produce irritation.

Dr. Roton had had twenty cases, and he was sure that many more had come under his notice in which a diagnosis had not been made. He thought that scurvy could be classed under the same head as the other hæmorrhagic diseases.

Dr. Forchheimer had seen seven typical cases. He thought that the condition of scurvy was brought about by some chemical change in the blood at present unknown.

Dr. J. Lewis Smith thought that many mistakes had been made in diagnosticating scorbhtus as rickets. It was a fact that scurvy of the mouth did not occur where the teeth were absent, as in old people where the teeth had fallen out or in young infants before the cruption of teeth. It was thought possible that there might be an association between rickets and scorbutus; in rickets the teeth were slow to appear, and this might account for the absence of the mouth symptom. Scorbutus was a disease of malnutrition, and was frequently found in children that had been fed exclusively upon milk for the first year of life.

Dr. A. Jacobi thought that the disease was more prevalent at certain times than at others, as when infectious diseases were rife. More cases had occurred in the first half of March, 1892, when the weather was particularly moist and disagreeable, than at any other time. The disease was not confined to the poorer classes, and was found most frequently where children were fed exclusively upon sterilized milk. This sterilization of milk at the expense of its chemical composition, rendering it innutritious, had been the cause of many deaths. The speaker thought that the symptoms of spongy gums could not be relied upon alone to mark scurvy, for if the teeth were absent the symptom would not appear. Some thought that the term scurvy ought to cover the ground for this condition, but might it not be only a symptom of a morbid state of the bloodvessels? Ulcerative stomatitis or gingivitis ought not to be mistaken for scorbutus. In the treatment of scurvy a mixed diet was relied upon-fruit, beef juice, milk, cereals, and phosphorus. The speaker related a case in which he thought an exhausting diarrhœa had caused, or been the exciting cause of,

Dr. L. EMMETT HOLT said that there was no doubt that scurvy was a dietetic disease. The greater number of cases that had come under his notice had been caused by an exclusive diet of Mellin's food. Cases of scurvy were rare in institutions for children, where sterilized milk was usually used, but not to the exclusion of everything else.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Eighty-eighth Annual Meeting, held in Albany, on Tuesday, Wednesday, and Thursday, February 6, 7, and 8, 1894.

The President, Dr. HERMAN BENDELL, of Albany, in the Chair.

(Concluded from page 346.)

The Inch-and-a-Half Incision and Week-and-a-Half Confinement in Appendicitis.—Dr. Robert T. Morris read a paper with this title, and stated that we had recently learned four principal things relative to appendicitis, and he now asked the members of the profession to accept a fifth point: First. We had learned that appendicitis was of such common occurrence that every general practitioner had many cases in his clientèle. Second. It was now generally known that multitudinous forms of abdominal inflammation were symptomatic of appendicitis. Third. Statistics showed that a late operation did not give much encouragement. Fourth. It was known that an early operation or an operation in the interval between attacks was attended with trifling mortality (with none at all in his experience), but that there was danger of ventral hernia resulting from the operation if a long incision was made.

The fifth point was this: We did not need to make a long incision in appendicitis cases that were operated upon at the outset of the inflammation, or in interval cases, as a rule; and there would be no hernias and no permanent scars if the surgeon would accept as standard the author's abdominal incision, which was an inch and a half in length, the divided structures

of the abdominal wall being united separately with fine catgut afterward. The author buried the stump of the appendix with Lembert sutures. The abdominal scar disappeared entirely, so that at the end of a few months it could not be seen. His death rate had been nothing at all in cases without pus, and physicians upon whom he depended for cases were now ashamed to have him find pus in the cases to which they called him. He did not know just where to look for danger in any of the cases operated upon at the time of his choice, but called the attention of members of the society to one danger in the use of carbonate of sodium for reversing peristalsis of the bowel. A note was at present going the rounds of the press to the effect that carbonate of sodium was useful in reversing peristalsis, but the author, in experimenting with rabbits, had accidentally discovered that carbonate of sodium on touching the ileum regularly produced intussusception in less than forty-five seconds. The mechanism of the intussusception consisted in spasm of a belt of circular muscular fibers of the ileum, and this portion was then quickly invaginated by the peristaltic action of the longitudinal muscular fibers. The author now used chloride of sodium for reversing peristalsis in all of his operations.

He stated that there was strong opposition to his plan of removing an infected appendix just as soon as it was discovered, but this opposition must fade away as soon as physicians generally could benefit from his experience, which was to the effect that appendicitis was an infectious exudative inflammation which did not disappear on the disappearance of the symptoms. He had removed a large number of appendices from patients who felt perfectly well but who could not obtain life insurance, or who feared recurrence, having had a previous attack of appendicitis. In all these cases he had found destructive processes in progress. Sometimes there was slowly progressing necrosis of the lymphoid tissue of the appendix; sometimes he had found tuberculosis or carcinoma insidiously beginning at the seat of the old inflammation; sometimes adventitious bands set snares for the bowel; and he had discovered that proliferating endarteritis, which must eventually lead to gangrene of the appendix, was common in very mild chronic cases. He had found proliferating endarteritis producing slow occlusion of the arteries of the appendix in three mild chronic cases in succession.

Surgeons were laughed at occasionally because they found normal appendices at an operation for supposed appendicitis, but he did not believe that proper examination had been made of the specimens. He had removed two or three appendices which were apparently perfectly normal, but the patients' symptoms had all stopped after the operation, and when cultures of bacteria and microscopic sections had been made from these specimens, it was found that they had been dangerously infected. The mucosa and adenoid tissue were undergoing destruction by the colon bacillus.

When his inch-and-a-half abdominal incision was employed in the removal of infected appendices, patients left the hospital at the end of a week and a half. If an incision two inches long was made, the patient would not be ready to leave until fourteen days after the operation, and if the incision was from two and a half to four inches long, eighteen days would be required for repair. Consequently he had adopted as a standard the inch-and-a-half incision and week-and-a-half confinement plan, which left no hernia and an evanescent scar.

By operating immediately in acute cases, he did not mean on the following day, but on the following hour. Physicians who did not accept this plan must lose a few patients that they did not expect to lose, and they must let very many patients suffer tediously and unnecessarily; but there would not be much further opposition, because physicians were only too glad to do the very best thing as soon as they had learned what it was. The insurance companies would not insure a patient who had ever had appendicitis and whose appendix still remained, if they were to note the character of the adventitious peritoneal bands which formed in these cases, and if they observed the persistence of appendicitis and of supplementary diseases in the appendices of patients who were thought to be quite well.

Appendicitis: The Connection between its Symptomatology and the Gross Anatomy of the Appendix .- Dr. Joseph D. Bryant, of New York, based his paper upon extensive pathological investigations. He had found that the fibrous tissue involved in the appendix was rarely the primary seat of the disease—only three times in a hundred and twenty six cases, The pain of the disease depended much upon its surroundings. the connective tissue involvement showing a different pain from the peritoneal. The pain was also modified by the size, situation, and mobility of the appendix. In forty per cent. of sixtysix cases seen by the speaker, the appendix had been freely movable, with a mesentery of varying dimensions. Sudden severe pain in the region of the organ was usually the first prominent symptom of the disease. The direction of the appendix was a matter of little importance, except in cases in which it was far from its usual location, especially if it dipped into the pelvis. The average length was three inches and a quarter for women, and three inches and a half for men. The pain was either direct or reflex, and might be referred to the seat of any of the spinal nerves implicated in the inflammatory process. The reflex pain was due to the influence of the abdominal sympathetic ganglia in the process. Tenderness on pressure, as a symptom, might be local or general, severe or mild, and varied with the location of the appendix, a dull tenderness indicating that the organ was located behind the colon, an acute tenderness that it was within the area of the peritonæum. A diffused general tenderness had little practical bearing upon the location of the appendix. Tension was another sign of importance, and might be limited to the area supplied by the nerve of the region of tension. Other points of importance in making a diagnosis were the presence of a tumor and its size, firmness, mobility, etc. A tumor was usually discoverable from the first to the eighth day of the attack, and most frequently on the third, fifth, or sixth. The conclusions which the author drew from his investigations were: 1. The location, size, and direction of the appendix have an important bearing upon the inflammation which it suffers. 2. The varying locations of the appendix and cæcum cause definite statements as to their location and position to be misleading.

Dr. H. MYNTER, of Buffalo, appreciated the importance of the anatomical points which had been elucidated by Dr. Bryant. The relations of the appendix to its mesentery were especially significant. If the mesentery was of considerable dimensions, an inflammatory proce-s would result in a local perityphlitic abscess. If the appendix was quite free in the peritoneal cavity, without any considerable mesentery, the inflammatory process would be severe in character, probably perforative. He presented specimens from two such cases, both of them fatal after operation. A wrong impression was derived from the glowing statistics of certain surgeons who did not appear to have any fatal cases, or at least did not report them. In his experience the severer forms of appendicitis were followed almost invariably by death, when operated upon, and if the New York surgeons were able to cure them he would be very glad to learn how they did it.

Dr. H. DURAND, of Syracuse, narrated a case which was not seen by him until perforation had taken place. The patient, a young man, was in a very bad condition, and was operated upon at night among very bad surroundings. Notwithstanding

the unpromising outlook, recovery was prompt and almost uneventful, showing that even desperate cases were not always hopeless.

Dr. Willy Meyer, of New York, knew of no New York surgeon who could boast of a clean record in operations for perforative appendicitis. Surgeons and physicians in that city certainly had enjoyed exceptional advantages in the study of this disease, owing to the abundance of material and the readiness and facility with which the physician could secure the aid of the surgeon when an operation was required. This had been very helpful in educating both the physician and the surgeon, and such advantages were necessarily wanting in a great degree in small cities and the country, where the means of communication were less satisfactory than in the metropolis. It was scarcely necessary to say that if a case was not seen until perforation had taken place the successful issue of an operation was hardly to be expected.

Dr. ROBERT T. MORRIS, of New York, did not entirely approve of the method of palpating the appendix which had been advocated, as the necessary manipulation might precipitate an acute attack of appendicitis. Dr. Bryant's statistics in regard to the length of the appendix were based mainly upon examinations made after death, and it must be remembered that the conditions at that time differed from those which existed before death. Peroxide of hydrogen had been recommended by one of the speakers for application to the peritonæum in cases of general peritonitis. Warm saline solutions were preferable when that condition existed, while the peroxide was to be used as an application to suppurating surfaces. Drainage by means of wicking should be employed in suppurative appendicitis. The results obtained by New York surgeons were better than those obtained by surgeons in other cities, because they saw their patients earlier in the history of the disease.

Dr. MYNTER wished to know whether successful results had been obtained by the last speaker after operations in cases in which gangrene and suppuration had been present.

Dr. Morris replied that in the severer cases death would undoubtedly follow operation, but he had operated in several cases of even desperate character in which recovery had taken place.

Dr. Edebohls stated that the conditions in chronic appendicitis were precisely the ones in which he had been able to palpate the appendix successfully. He had operated in a number of cases in which he had been able to verify the diagnosis made prior to operation. Instead of irrigating the abdominal cavity, he preferred to wipe away all offending material with dry, soft cloths. As to the cases in which perforation was present, one was sometimes disappointed by recovery, while in simple cases in which the conditions seemed favorable for recovery the patients died.

Dr. A. Vanderveer, of Albany, quite agreed to the statement that the conditions for operating with rural surgeons were often less favorable than with those who lived in the large cities, and many hours might be consumed before the rural surgeon could reach his case. In acute perforative appendicitis a fatal result was frequently inevitable, even though one operated immediately after the accident occurred.

Dr. Bryant was impressed with the fact that no condition in the entire field of surgery called for more careful judgment than perforative appendicitis with suppuration. In his experience it was the rule that all such cases would terminate fatally.

Intestinal Perforation in Strangulated Hernia,—Dr. W. B. De Garmo, of New York, speaking on this subject stated that it was not unusual in opening the hernial sac to find congestion, gangrene, and perforation of the intestine. The first question, after releasing the strictured bowel, was whether it

should be returned or removed. The free use of hot water upon the injured organ would enable one to decide that it could with safety be returned. Shock would be diminished by the influence of the hot water and clots and ecchymoses upon the bowel would be removed. The intestine should be drawn out and carefully inspected until healthy structures were reached, all adhesions being separated. It was inadvisable to tap the distended bowel even with a fine hypodermic needle. Lacerations and perforations of the gut might be due to taxis or force in separating adhesions. In either condition extravasation of the intestinal contents was to be expected, and was, of course, a source of danger. If the intestinal wounds were carefully sutured, the sutures might be passed with the faces without injury. The treatment of the seriously injured bowel would consist in resection, the making of an artificial anus, or fæcal fistula. The last of these was preferred by some surgeons, and was less objectionable than an artificial anus. If resection was required, the end-to-end suture was preferable to lateral anastomosis. Murphy's button was available for this operation, also the method which had been recommended by Maunsell.

Recent Methods of Gastrostomy for Stricture of the Esophagus.—Dr. Willy Meyer, of New York, remarked that this condition had formerly been one of the most troublesome which the surgeon was called upon to treat, as the patient was not generally seen until very late in the history of the disease. Recent methods and treatment offered great improvement over those formerly used. It was now unnecessary that a patient should die of starvation. The operation of Fenger was the one which had formerly been employed, but it was unsatisfactory on account of leakage at the side of the wound, and was now practically abandoned.

Von Hacker's operation was an improvement upon Fenger's. The incision was made along the outer border of the left rectus muscle, the stomach was drawn forward and attached to the wound, and after two days the stomach was incised.

Habn's incision was similar to that used by Fenger, but in addition there was a transverse incision which prevented the danger from leakage.

In Witzel's operation, after the stomach had been incised a tube was introduced into the œsophagus, covered with a fold of the stomach, and the fold secured by sutures. The speaker had had several successful operations by this method.

In the Szabanijew-Frank operation an oblique incision was made over the stomach, the latter brought forward, secured, and incised, and an osophageal tube secured in the wound. In general, success by any method would be much better if the operation was performed early, before the patient suffered with inantition.

Some Cases of Brain Surgery.—Dr. H. Mynter, of Buffalo, narrated several cases in which operations upon the brain had been performed by him with greater or less loss of brain substance. Only sterilized water should be used for irrigating wounds of this character.

The Action of Scopolamine on the Eye.—Dr. Thomas R. Poolex, of New York, called attention to this new mydriatic, isomeric with cocaine, possessing all the good effects of atropine without any of its bad ones. It was said to retard the action of atropine when both were used. It had been asserted that it could be used for a long time in a solution equivalent to a one-per cent. solution of atropine without disturbing the stomach, but the speaker was doubtful of the correctness of this statement. In iritis and scleritis it was useful in cases in which atropine was not tolerated, also in glaucoma, and it did not increase the intra-ocular pressure. The salt used was the hydrochloride, and a solution of one fifth of one per cent. was five times as efficient as a solution of atropine of equal strength. In

determining the anomalies of refraction it would cause complete paralysis of accommodation in from ten to fifteen minutes, and the mydriasis would continue from twenty-four to forty-eight hours. There were defects in visual acuteness after recovery from its immediate effect. A toxic effect had been reported in three cases. In the treatment of ulcer of the cornea it had given good results. The present indications were that it was a valuable addition to the available list of mydriatics.

Urethral Caruncle,-Dr. E. N. Liell, of New York, included under this term the vascular growths about the meatus urethræ of soft and spongy texture in women. They were irregular in outline, were of granular appearance, and varied in dimensions from those of a pin's head to those of a small marble. They were composed principally of very vascular hypertrophied papillæ, with abundant nerve supply, and were generally sessile. A single one might be present, or there might be quite a group of them. They were to be found not only along the borders of the meatus, but upon the wall of the urethra itself, and especially in middle-aged married women. Their ætiology was obscure, but they were usually associated with some other morbid conditions of the genitals. They seemed to cause frequency of micturition, and were the source of severe pain and tenesmus. They were prone to return after removal, especially if the removal had been incomplete; hence their removal by dissection was preferable to that by torsion. The operation wound should be systematically treated with a strong solution of nitrate of silver until their eradication was assured.

Uræmic Hemiplegia, -Dr. R. W. Wilcox, of New York, stated that this condition was probably due to ædema of the brain with serous effusion. The symptoms were vertigo, gastric and cardiac disturbance, cedema of the face, etc. The urine was usually albuminous before hemiplegia occurred. If hyaline casts were found in the urine, the condition of contracted kidney was probably present; there might be albuminuric retinitis. Lancereaux had shown that the œdema of the brain might be transferred from one side to the other, with a corresponding change in the hemiplegia. The superficial reflexes were impaired, and the temperature was elevated. Hæmorrhage and softening of the brain might result. The tendon reflexes were sometimes normal and sometimes exaggerated. The hemiplegia usually disappeared after a time, but it might recur. The prognosis was grave if the renal involvement was considerable. The treatment consisted in venesection and the use of drastic purgatives, diuretics, and heart stimulants.

Dr. E. D. Fisher, of New York, thought it was very difficult to distinguish uramic hemiplegia from syphilitic disease of the cerebral blood-vessels. In some cases an autopsy had shown that the serous effusion referred to was the real cause of the trouble. It was doubtful whether uramia per se was ever the cause of hemiplegia.

Dr. W. W. Seymour, of Troy, thought the importance of determining the volume of urea in cases of this character was very great. The fluctuations of this constituent of the urine were considerable. The determination of the urea was in many cases of greater significance than the determination of the volume of albumin.

The Barber's Shop as a Source of Contagion.—Dr. George T. Jackson, of New York, called attention to the great importance of this subject as a matter of personal hygiene. There was great difficulty in disinfecting some of the instruments used by barbers, especially the hair-clipper. Ringworm of the scalp, syphilis, alopecia areata, and numerous other annoying diseases were in many instances directly traceable to the barber's shop. The finger-nails of the barber, the towels used, and the headrest of the chair were also sources of infection. In France and Germany stringent rules had been adopted to prevent the

spreading of disease by such means. This paper was presented in the hope of arousing professional opinion to the importance of the subject.

Dr. F. C. Curts, of Albany, called attention to the fact that it was not a very long time since the barber had been one of our fraternity. We criticised the practice of the midwife, and said it was important than the barber should receive similar attention. Probably the milder varieties of disease mentioned were communicated much more frequently than the severer ones. It was time that public attention was called to the importance of the subject.

Dr. McCracken, of West Troy, had been able to trace one hundred and twenty-six cases of ringworm of the scalp, in a public institution under his care, to the use of a single hair-clipper. The disease had ceased to appear after the objectionable instrument was disposed of. Thus, the statement of the reader of the paper was abundantly verified.

The Treatment of Glycosuria. - Dr. W. B. VANDERPOEL, of New York, read a paper upon this subject. The climate, he said, should be suited to the patient's condition, also his clothes, exercise, and diet. Early in the disease, sugar, starch, and the carbohydrates in general should be avoided, while at a later stage a mixed diet was preferable. If fats were given early in the disease, emaciation would be avoided; in the later stages they should be withheld. It was difficult to find a good substitute for wheat bread. Pavy's flour furnished the best substitute at present. The medicinal treatment might include the use of opium, bromides, lithium, arsenic, the coal-tar derivatives, ergot, Carlsbad and Vichy salts, iodoform, and lactic acid. Jambul and pilocarpine were useful if not given in too large doses. Oxygen should be given freely. In some cases transfusion of blood was indicated. The animal extracts had been found efficient. Diabetic coma was sometimes avoided by a judicious combination of carbohydrates with albuminoids. Life might be prolonged and the patient made comfortable if the disease was not cured, by careful study of all the condi-

Dr. A. II. Buckmaster, of New York, read a paper with this title. He said that the occurrence of hæmorrhage after cœliotomy was frequent. Operators but rarely reported their cases, and many patients who had died on account of hæmorrhage were classed under the head of deaths from peritonitis. The author explained this in the following manner: In many of these cases only an incomplete autopsy was made and no blood was found in the pelvic cavity. An incipient peritonitis was found, and this was given as a satisfactory cause of death. In these cases hæmorrhage had been feared and the foot of the bed elevated so that the blood gravitated under the diaphragm. Attention was called to the danger of allowing such statistics as were commonly published to be accepted by the courts as what

Hæmorrhage after Cœliotomy; its Place in Statistics,-

might be expected of the well-educated pelvic surgeon.

In addition to the well-known causes of hæmorrhage, the speaker dwelt on a cause to which he had first called the attention of the profession. Since then Dr. Polk and Dr. Coe had confirmed his observations. The cause alluded to occurred in the use of the Trendelenburg posture. After the hips had been elevated for some time, the blood pressure in the pelvis was much diminished. When the hips were lowered, the pressure was greatly increased and vessels would bleed readily which before had shown no evidence of loss of blood.

The writer narrated a case of hæmorrhage after laparotomy, and presented a carefully prepared pulse, temperature, and respiration chart.

With so many uncontrollable causes of hæmorrhage outside of the pelvis, where they could be noted immediately, it was

not surprising that so many cases of hæmorrhage existed in the pelvis, where the only signs were those revealed by the pulse and the drainage-tube, when this latter means was available.

# Book Notices.

An American Text-book of the Diseases of Children. Including special chapters on Essential Surgical Subjects; Diseases of the Eye, Ear, Nose, and Throat; Diseases of the Skin; and on the Diet, Hygiene, and General Management of Children. By American Teachers. Edited by Louis Staer, M. D., Physician to the Children's Hospital, etc., Philadelphia. Assisted by Thompson S. Westcott, M. D., Attending Physician to the Dispensary for Diseases of Children, Hospital of the University of Pennsylvania. Philadelphia: W. B. Saunders, 1894. Pp. xiv-1190. [Price, \$7.]

Tms book is the joint product of sixty-three contributors, and embraces many well-known names. The purpose has been, the editor states in the preface, "to present to the profession a working text-book which shall be closely limited to, while completely covering, the field of pædiatrics." From a careful examination of the book it would appear that he has fallen short of his ideal. A good deal of matter has been introduced which pertains more to general medicine and surgery than to pædiatrics, and many subjects belonging exclusively to early life have been passed over with very brief notice, and some of them omitted altogether. Thus we find an article of twenty pages upon Asiatic cholera, an excellent one, but to our mind out of place in such a text-book; again, fifteen pages are given to the subject of vesical calculus; and twenty-two pages to tracheotomy. We find, on the other hand, the whole subject of pneumonias of all varieties occupying but fifteen pages, chronic hydrocephalus dismissed in one page, and tubercular meningitis filling four pages and a half. The subject of stomach-washing is barely alluded to, and then merely in a casual manner. Pseudodiphtheria is given no place whatever. These examples will suffice to illustrate the point that the space of the book has not been well divided among the different contributors.

The first thirty-six pages are given to the clinical investigation of disease and the general management of children, and
are by the senior editor. This is essentially a reprint from the
author's book upon The Diseases of the Digestive Organs, with
some minor omissions. In this we find the following surprising
statements: "At birth the length [of the child] is about sixteen
inches. . . . The growth is quickest during the first week of
life. . . . In the first year there is an increase of from five to
six inches and a half." These statements are at variance with
those of every writer known to us. Twenty inches is universally recognized as the average length of a full-term child both
in Europe and in America. It is equally true that the majority
of infants do not grow during the first week, and, further, that
the average gain in length during the first year is from six to
nine inches.

The general directions given for the examination of sick children are excellent. The statements on the subject of infant feeding are temperate and sensible, and will appeal to most readers as exceedingly good. The space given to feeding in the second and third years is too small; this important subject should have been given a full discussion.

The second chapter, upon the chemistry of milk and artificial foods, by Albert Leeds, Ph. D., is an innovation and an exceedingly good one. Too little knowledge exists upon this subject.

The third chapter, upon exercise and massage, is a curiosity. We wonder how the editor could have admitted such an article to his book. In it we are told that "the homunculus (!), when fully able to cruise about the room or garden, should do so, clambering up and tumbling down. So shall there come growing consciousness of capacities and limitations, so learn to save the imperilled head by use of hands, and gleefully secure and inspect covered objects."

The diseases incident to the newly born are treated by Dr. E. P. Davis, of Philadelphia. These have been given altogether too little space. In the chapter on birth palsies, Erb's paralysis is not even mentioned.

The best group of articles in the book are those upon the general diseases. The subject of tuberculosis is treated by Osler in his usual thorough, incisive, and exact manner. The chapters on hereditary syphilis, by Chapin, typhoid fever and influenza, by Earle, and diphtheria, by Dillon Brown, are all excelent.

The writer upon scarlet fever states positively that this is a microbic disease, a question which we believe has not yet been settled. Too much stress appears to be laid upon the observations of Edington, whose work has not been confirmed by subsequent investigations. Very few evidences of original observation are seen in this article. The temperature charts are copied from Ashby, and most of the treatment is quoted from J. Lewis Smith.

In the article on diphtheria strong emphasis is very properly laid upon the local treatment, and very little stress is put on the subject of internal medication—a point in which we can agree with the writer. The author excludes from the term "diphtheria" the cases in which the Loeffler bacilli are absent, although no special discussion of pseudo-diphtheria is given. There is no adequate description of diphtheritic paralysis.

Most of the blood diseases are exceedingly well treated. The sections on diseases of the digestive organs are disappointing. The dyspepsia described is that of older children, but not of infancy. The classification adopted for the diarrhœal diseases is "Acute and Chronic Intestinal Indigestion," "Acute, Subacute, and Chronic Milk Infection." This classification seems to us of rather doubtful propriety.

In the section on diseases of the nervous system, the articles by Peterson upon abscess, tumors of the brain, and cerebral palsies, are all excellent. Too much space, we think, has been given to rare nervous affections—e. g., eight pages to tumors of the spinal cord; six pages to Raynaud's disease; and six pages to acromegaly, more than that devoted to tubercular meningitis.

Under the head of pulmonary diseases, the articles by Pepper on pneumonia are disappointing; that on pleurisy, by Koplik, is full and accurate and an excellent presentation of the subject. Crandall's article upon the heart is worthy of special mention.

Many articles in the book give evidence of comparatively little original observation or research. The colored plates, almost without exception, are poorly executed, and several are so bad as to be positive caricatures—e. g., that of the hæmorrhages in the newly born, on page 74, and the plate on tinea favosa, on page 1092. The reproductions from photographs are most of them excellent—e. g., those showing the operation of intubation, the plates of the various micro-organisms, that of psoriasis, and that of syphilitic teeth.

The printer's work has been well done: the book is remarkably free from typographical errors, and, best of all, it is furnished with a good index.

While the book has many points of excellence, it can not be said by an impartial critic to be, as the preface states, "thor-

oughly abreast with the rapid advance which is constantly made in this branch of our profession."

Treatment of the Diseases of the Stomach and Intestincs. By Dr. Albert Mathieu, Physician to the Paris Hospitals. New York: William Wood & Co., 1894. Pp. viii-294.

As the author truly states, the increase in our knowledge of the chemistry of gastric digestion, as well as the advances made in our knowledge of self-intoxication of intestinal origin, has materially changed the views entertained by the profession in regard to the pathology of gastro-intestinal diseases. He has accordingly endeavored to show clearly in what measure these new ideas have modified the indications for treatment, and, by setting forth the objects that the therapeutist has to attain, he indicates the means at his disposal to insure their accomplishment. He holds that the study of the affections of these two portions of the digestive apparatus can not be separated, because the pyloric and ileo-cæcal valves are anatomical boundaries, rather than barriers in the domain of normal and morbid physiology.

The consideration of the subject is divided into three parts. In the first the technique of diagnosis is explained. More stress, it seems, should have been laid on the symptom of indicanuria indicating the degree of intestinal indigestion; but as a rule the methods of examining the contents of the stomach, bladder, and intestine, and the clinical significance of the results of the examinations, are satisfactorily described.

The second part consists of general considerations on diet. Mathieu calls attention to the uselessness of administering peptones, because their composition is too complex and variable, while it has never been shown that artificially prepared peptones are susceptible of absorption and assimilation. Extracts of meat he also considers as without alimentary value. Milk is the most desirable food in most gastropathies, and the author confirms the favorable reports regarding the value of meat powder. Alcohol, in the form of rum or brandy, may be given but red wine, on account of its acidity, should be interdicted. Hot drinks should be substituted for cold fluids.

The third part of the volume is devoted to the treatment of the principal forms of dyspepsia and of the most common symptoms of gastro-intestinal diseases; in this category are included hyperchlorhydria, nervo-motor dyspepsia, gastrectasia, gastralgia, vomiting, disorders of appetite, constipation, diarrhosa, gastric and intestinal hamorrhage, and acute indigestion.

The fourth part treats of the diseases of the stomach and intestine. The therapeutic indications are well considered, and the suggestions in the volume are likely to prove useful to all physicians.

Transactions of the Royal Academy of Medicine in Ireland.— Vol. XI. Edited by William Thomson, M. A., F. R. C. S., General Secretary; Surgeon to the Richmond Hospital, Dublin. Dublin: Fannin & Co., 1893. Pp. xxxix-518.

This volume contains the papers read before the various sections of the academy during the session of 1892-'93, as well as a list of the members, the rules, and the reports.

The professional papers have been carefully prepared, and treat of interesting conditions. Dr. J. O'Carroll, in a paper on Saturnine Encephalopathy, suggests that there is a direct influence of lead on the smaller cerebral vessels and the neuroglia surrounding them. Mr. J. B. Story reports five cases of glaucoma in persons between the ages of thirteen and thirty five. Mr. J. B. Coleman and Dr. J. O'Carroll report a case of myelosyringosis. Dr. John Knott has a note on the necessity of diet in cases of pin-swallowing. Dr. J. Knox Denham urges the erection of special hospitals for the treatment of pulmonary consumption. Dr. J. Knott describes four cases of subjective

ozaena in males. Dr. W. Beatty reports a case of myxordema successfully treated by injections of extract of sheep's thyreoid. Mr. J. Burgess gives the history of a fatal case of septicaemia following the extraction of a molar tooth. Dr. W. R. Dawson, in a paper on The Diagnostic Value of the Diazo-reaction, concludes that it does not afford positive proof of the existence of typhoid fever. Sir William Stokes commends the advantages of Esthlander's operation in a paper on that subject. Mr. Thornley Stoker, in a paper on The Operative Treatment of Trifacial Meuralgia, advises neurectomy of the fifth nerve as the best surgical procedure. Dr. C. B. Ball reports twelve cases of laparo-colotomy for rectal cancer. Dr. Kendal Franks furnishes an interesting paper on movable kidney. Lack of space forbids an enumeration of all the papers in this volume, that well maintains the excellent standard of its predecessors.

Venereal Memoranda. A Manual for the Student and Practitioner. By P. A. Morrow, A. M., M. D., Clinical Professor of Venereal Diseases in the University of the City of New York, etc. New York: William Wood & Co., 1894. Pp. iv-332.

In this, the second, edition of his little manual, the author has taken the opportunity to include the latest advances made in our knowledge of veneral diseases during the eight years that have elapsed since the work first appeared.

In the additions that have been made in reference to the microbian theories of the atiology of venercal diseases and to recent therapeusis the author has not lost sight of that brevity associated with accuracy that characterized the former edition.

We believe that the book is very useful.

#### BOOKS, ETC., RECEIVED.

A Practical Treatise on the Diseases of the Hair and Scalp. By George Thomas Jackson, M. D., Professor of Dermatology, Woman's Medical College, New York Infirmary, etc. New, Revised, and Enlarged Edition. New York: E. B. Treat, 1894. Pp. 21 to 414. [Price, \$2.75.]

Aero-therapeutics, or the Treatment of Lung Diseases by Climate, being the Lumleian Lectures for 1893, delivered before the Royal College of Physicians, with an Address on the High Altitudes of Colorado. By Charles Theodore Williams, M. A., M. D. Oxon, F. R. C. P., Senior Physician to the Hospital for Consumption and Diseases of the Chest, Brompton, etc. London and New York: Macmillan & Co., 1894. Pp. xii-187. [Price, §2.]

Methods of Pathological Histology. By C. von Kahlden, Assistant Professor of Pathology in the University of Freiburg. Translated and edited by H. Morley Fletcher, M. A., M. D. Cantab., M. R. C. P., Casualty Physician to St. Bartholomew's Hospital, etc. With an Introduction by G. Sims Woodhead, M. D., Director of the Laboratories of the Conjoint Board of the Royal Colleges of Physicians (Lond.) and Surgeons (Eng.). London and New York: Macmillan & Co., 1894. Pp. xi-171. [Price, \$1.40.]

The Human Element in Sex. Being a Medical Inquiry into the Relation of Sexual Physiology to Christian Morality. By Dr. Elizabeth Blackwell. New Edition. London: J. & A. Churchill, 1894. Pp. 76. [Price, 2s. 6d.]

The Johns Hopkins Hospital Reports. Report on Typhoid Fever. Vol. LV. No. 1. 1894.

Notes on Naval Hospitals, Medical Schools, and Training School for Nurses, with a Sketch of Hospital History. By J. D. Gatewood, M.D., Passed Assistant Surgeon, United States Navy.

The Transactions of the Third Annual Meeting of the Asso-

ciation of Military Surgeons of the National Guard of the United States. Held at Rush Medical College on August 8th, and at the United States Government Building, Jackson Park, Chicago, August 9 and 10, 1893.

Memorial by the Managers of the New York State Reformatory at Elmira, relating to the recent Investigation by the State Board of Charities, 1894.

The Difference between Certain Wounds inflicted by the Projectiles of Large and Small Caliber Hand Weapons. By Captain Louis La Garde. [Reprinted from the International Medical Magazine.]

A Bacteriological Study of Four Hundred Cases of Inflammation of the Throat, occurring in Diphtheria and Scarlet Fever, with Especial Reference to Pathogenesis. By John Lovett Morse, M.D. [Reprinted from the Medical and Surgical Reports of Boston City Hospital.]

A Few Things that may Add to the Convenience of Railroad Surgeons, with an Article on the Bloodless Amputation at the Hip Joint at One Sitting and with One Needle. By Stewart Leroy McCurdy, M. D., Dennison, Ohio. [Reprinted from the Railroay Age and Northwestern Railroader.]

The Treatment and Cure of Chancre with Peroxide of Hydrogen. By Willard Parker Worster, M.D. [Reprinted from the Journal of Cutaneous and Genito-urinary Diseases.]

Laparo-hysterotomy: its Indications and Technique. By N. Senn, M. D., Chicago. [Reprinted from the American Journal of the Medical Sciences.]

Tuberculosis in Relation to Animal Industry and Public Health. By James Law, 1894. [Bulletin 65.]

# Miscellany.

The Proteids of the Thyreoid Gland.—In the March number of the Journal of Physiology there is an article by Dr. Frederick Gourlay in which he gives an account of his experiments in the form of answers to questions, largely as follows:

"Does the thyreoid contain peptone? As clinical experience has shown that thyreoid feeding in cases of myxcedema is as efficacious as injection of thyreoid juice subcutaneously, it is evident that the active principle is not destroyed by the process of digestion; therefore it was not a priori improbable that a peptone or proteose would possibly be obtainable from the fresh thyreoid. But no peptone is present in the fresh thyreoid."

"Does the thyreoid contain proteoses? The answer to this question is also a negative one. The method adopted was Devoto's."

"Does the thyreoid secrete mucin? Mucin is a glucoside, a compound of a proteid and a carbohydrate (animal gum), and by boiling with dilute sulphuric acid it yields a reducing sugar. Nucleo albumin, which is apt to be mistaken for mucin, does not do this. Two lobes of the thyreoid of an ox were scraped down, the capsule and trabeculæ of connective tissue being removed as much as possible. The pulp was then boiled with dilute sulphuric acid in a flask for two hours and a half and filtered. The filtrate was neutralized with alkali, and boiled with Fehling's solution. No reduction occurred. Ia another experiment similarly performed, the final filtrate was neutralized, boiled with crystals of sodium sulphate, and filtered to remove proteid matter. The filtrate, on being tested with Fehling's solution, gave no reduction even after long boiling. The colloid material in the alveoli of the organ is therefore not mucin.

"Is nucleo-albumin obtainable from the thyreoid? Two methods of preparing this substance were adopted.

"(1) Wooldridge's method. The finely divided organ was extracted for about twenty-four hours with a large quantity of distilled water. The extract was poured off, and to it weak acetic acid was added. After twenty-four hours a flocculent precipitate separated out and fell to the bottom of the vessel. This was washed by decantation, and finally collected on a filter. It was subjected to gastric digestion, and after some days a residue was left which was soluble in dilute alkali and reprecipitated on adding acetic acid. It was, moreover, rich in phosphorus. In other words, the residue consisted of nuclein. By Wooldridge's method, therefore, nucleo-albumin is obtainable from the thyreoid, The yield, however, by this method is not large, and sometimes the liquid became cloudy on adding the acetic acid, little or no precipitate falling subsequently. If, as I believe and hope to show, the nucleo albumin is in part derived from the colloid matter of the gland, this fact agrees well with what is stated in the text-books to characterize the colloid matter and distinguish it from mucin-namely, the fact that it is not readily precipitable by acetic acid.

"(2) Halliburton's method. Some thyreoids were cut up very small and ground in a mortar with about an equal quantity of sodium chloride. A small quantity of distilled water was added and the whole thoroughly mixed. The resulting mass was exceedingly viscid. This was then poured into a large volume of distilled water. The pieces of tissue fell to the bottom of the vessel, and a large precipitate of whitish flakes took place all through the water. These formed cohesive strings which floated up to the surface of the water, where they formed a thick scum. On subjecting this to gastric digestion, the residue was again found to consist of nuclein.

"Nucleo-albumin can, therefore, be obtained from the thyreoid by both the methods adopted, but more readily by Halliburton's sodium-chloride method than by Wooldridge's aceticacid method.

" Does the thyreoid nucleo-albumin cause intravascular coagulation? Wooldridge, Halliburton, Pekelharing, and others have abundantly demonstrated that nucleo-albumins obtained from various cellular organs produce intravascular thrombosis when injected into the circulation. It therefore became necessary to test this question with the nucleo-albumin of the thyreoid. The experiments were performed on rabbits. . . . The animal being anæsthetized with ether, and the jugular vein exposed, one hundred and fifty cubic centimetres of a solution of thyreoid nucleo-albumin (prepared by the sodium chloride method and dissolved in a dilute solution of sodium carbonate) were injected. This did not cause the death of the animal; it was therefore killed by asphyxia, and the blood was found still fluid, and clotted in the usual manner on removal from the body. This single negative result was not regarded as conclusive, as one does occasionally obtain inactive preparations even from the thymus. It was, moreover, performed on a white rabbit, and white rabbits appear to be least affected by such injections. It was therefore repeated, and it was found that some preparations caused slight, and others very extensive, intravascular coagulation. In all, six experiments were performed, the animal being in every case anæsthetized with ether."

"What is the source of the thyreoid nucleo-albumin? As nucleo-sibumin is obtainable from a great many organs which are composed chiefly of cells, it becomes a question whether the nucleo-albumin of the thyreoid is derived from the cells lining the aciai or from the colloid contents of the aciai.

"It was here that the recently introduced microchemical method of Lilienfeld and Monti came to my assistance. This

method has for its object the microscopic localization of phosphorus in the tissues. Stated briefly, it consists in taking sections or teased portions of fresh tissues, soaking them in a solution of ammonium molybdate and subsequently reducing in a twenty-per-cent. solution of pyrogallic acid in water, or better in ether. The sections are then dehydrated, cleared, and mounted in Canada balsam in the usual way. The resulting coloration, yellow, brown, or black according to its intensity, indicates the presence of phosphorus. As a slight modification I found it advantageous, previous to transferring the sections to the ethereal pyrogallol solution, to wash them for a few seconds in a vessel of ether to which about a tenth of its bulk of water had been added. I have also found that fixing the tissues by a half-per-cent, solution of osmic acid does not interfere with the subsequent treatment by Lilienfeld's method. This also prevents the shrinkage, seen in alcohol-hardened sections, which also I sometimes used.

"Before proceeding to apply this method to the thyreoid, I made, with Professor Halliburton's assistance, a number of preliminary experiments with other tissues. In the case of the thymus the cells were stained a brown color, the nuclei a deeper tint; the corpuscles of Hassall were more deeply pigmented than the rest, and the muscular coats of the small vessels stood out very prominently. In the case of cartilage, we confirmed the observation of Lilienfeld and Monti that the matrix remains uncolored, the protoplasm of the cells is brown, and the nuclei dark brown to black. In the case of the umbilical cord, the contrast between the unstained mucinoid matrix and the connective-tissue cells is very well brought out. In the thyreoid the staining is just about equally intense in the cells and in the colloid matter they encircle and presumably excrete. Both are dark-yellow or brown. In the cells themselves there is little or no differentiation to be noticed between nuclei and cell-protoplasm. This does not appear to be due to lecithin, for the process is equally effective in alcohol-hardened specimens."

"To sum up, the microscopic method of localizing phosphorus demonstrates that the nucleo-albumin obtained originates in large measure from the colloid matter of the acini, and is not merely a product obtained from the cellular constituents of the organ."

" Do these experiments throw any light on the question, To what does thyrooid juice owe its curative effect in myxadema? This difficult question can only be answered at present in a very tentative manner. It has been demonstrated that the colloid matter in the interior of the vesicles ultimately finds its way via the lymphatics into the blood stream. This internal secretion is absent in the diseases variously known as sporadic cretinism, cachexia strumipriva, and myxœdema; and, having adduced evidence that the colloid matter consists of or contains a nucleo-albumin, it is not altogether improbable that the nucleoalbumin is the active principle the deprivation of which causes the disease, and the administration of which cures it. If this is so the ultimate fate of the nucleo albumin must still remain a question that requires an answer. It is not possible at present to say whether it is used as such for the nourishment by the tissues or whether it is first broken up and its nuclein liberated. Moreover, the material which constitutes the active principle of the thyreoid is not destroyed by the gastric juice, and nucleoalbumin fulfills this condition, in so far at least as its nuclein part is concerned. The question might be more definitely answered if nuclein were actually tried in the treatment of myxedema; and, further, it would have to be shown whether or not thyreoid nuclein differs in this respect from nuclein prepared from other sources. I have not myself had the opportunity of testing the matter, having only yet had one case of the disease under my own care which was cured by thyreoid feeding. To

this I may add that, testing the diffusibility of the thyreoid juice by means of parchment-paper dialysers, I found a distinct amount of proteid matter in the dialysate after twenty-four hours. Whether this has any bearing on its rapidity of absorption in the alimentary canal, one would not like to state definitely, seeing that evidence has recently accumulated to show that absorption is a very different process from physical diffusion.

" Does the thyreoid contain a ferment which dissolves mucin? The term myxodema was originally given to that disease because it was believed that its chief feature was a swelling of the subcutaneous and other connective tissues, due to accumulation of its mucinoid stroma. It has, however, since been shown that the disordered metabolism that follows cessation of the thyreoid's functions goes deeper than that, and that excess of mucin is by no means a constant accompaniment of the disease. Moreover, in those cases where there is more mucin than normal, the slight increase can be accounted for by the fact that in all young connective tissues there is a smaller proportion of the fibrous and a larger proportion of the interfibrous material than in the fully formed tissue. Nevertheless it was thought advisable to try whether the thyreoid juice does contain a ferment that dissolves mucin, especially as the hypothesis of a ferment has been worked to explain the curative value of thyreoid treatment.

"White and Davies have prepared from the thyreoid a material which has curative value, and the method of preparation was that used for preparing ferments from other organs. An extract of thyreoid was made with equal parts of glycerin and water. The filtered fluid was then acidulated with phosphoric acid and calcium hydrate added until an alkaline reaction was obtained. The resulting precipitate was filtered off as quickly as possible, washed, and dried over sulphuric acid. The white powder so obtained is the curative agent in question. The fact that this has been used with clinical success does not, however, as Mr. White admits, prove the ferment hypothesis. Having prepared the substance by this method, I obtained a supply of mucin from umbilical cords. The mucin was extracted by means of dilute baryta water, and then precipitated by acetic acid from this solution. This was subjected in test-tubes kept at the temperature of the body to the action of fresh thyreoid juice, and in other cases to that of the supposed ferment preparation. But the results obtained were wholly negative. no case was any change observable in the mucin or in its solubilities."

The general results of the experiments are summarized as follows:

"1. The thyreoid does not contain or yield any peptone or proteose.

"2. Its secretion is not mucin, as it yields no reducing sugar on treatment with dilute mineral acid.

"3. The only proteid that can be obtained in any quantity from it is a nucleo albumin.

"4. This is derived, at any rate partly, from the so-called colloid matter in the acini, as the microchemical method of Lilienfeld and Monti for the localization of phosphorus shows that it contains phosphorus.

"5. Experiments which had for their object the finding of a ferment in the thyreoid that dissolves mucin led to negative results; and it is suggested with all reserve that the nucleo-albumin is the material to which the thyreoid treatment of myxocdema owes its usefulness.

"6, Thyreoid nucleo-albumin causes intravascular coagulation."

Hysterical Facial Neuralgia.—At a recent meeting of the Société médicale des hôpitaux, reported in the Mercredi médical

for March 7th, M. Gilles de la Tourette remarked that the best-known form of bysteria was the paroxysmal convulsive attack, and that had for a long time obscured all other forms. He reminded his hearers that in 1891 he had described a form of hysterical paroxysm characterized by pain in the course of the trigeminus nerve closely simulating tic douloureux, with which it had been confounded up to that time. The paroxysm was preceded by an aura, and ended in a special derangement of mind and the passing of an abundance of clear urine. The speaker then presented a patient, a man fifty-four years old, who was affected with this derangement. He had hemi anæsthesia on the left side, and on the right side of the face there was a hyperesthetic hysterogenous zone irritation of which gave rise to the paroxysmal phenomena that he had described.

A Case of Death from Nitrous-oxide Anæsthesia,-Mr. John Adams lately read a paper before the new Society of Anæsthetists, of London, in which he gave an account of a death under the influence of nitrous oxide. The paper is published in the Lancet for March 24th. It seems that the patient, who appeared to be in good health, visited a dentist about an hour after a light luncheon. After waiting half an hour, he was admitted to the operating room, where he said that he wished to have a second right upper molar extracted while he was anæsthetized with gas. There was nothing tight about his neck, and there was nothing in his appearance to lead to the supposition that he was not a fit subject for the anæsthetic. He had a small, receding jaw and a short, thick neck, but there was no abnormal swelling of any kind which prevented his closing his mouth, as a published report had stated. An ordinary prop, attached to a strong fishing line, was placed between the upper and lower central incisors. After he had taken three or four inspirations of nitrous-oxide gas he took off the face-piece and said he felt nervous, but at the patient's own request the author went on with the administration. The man's breathing was shallow but regular, and when he had taken about two thirds of the usual quantity of gas the tooth was extracted quickly and without any difficulty. The breathing at once grew irregular and the man became more cyanosed, his muscles were rigid, and after three or four respirations he ceased to breathe, but there did not seem to be imminent danger. As the breathing was not continued, the prop was removed at once, the patient was transferred to the floor, and artificial respiration was begun within thirty seconds after the extraction, the tongue being pulled forward. The heart was beating regularly but not strongly, the body remained rigid, and there was no inspiratory effort. In about two minutes after the extraction of the tooth two or three expirations took place, showing, says the author, that there was no considerable obstruction in the larynx. Nitrite of amyl was applied to the nose and mouth, but the author judges that it could not have affected the patient, inasmuch as no inspirations took place. A subcutaneous injection of ether was given in the præcordial region, as the action of the heart had now become feeble. These measures having failed, tracheotomy was performed within three minutes of the discontinuance of the administration of the gas. The tracheal wound was kept open, and when artificial respiration was resumed about an ounce of mucus was forced out, only slightly blood-stained. Although air could be heard passing in and out of the opening in the trachea, there was no voluntary respiratory effort from first to last. The patient had now become still more cyanosed, and the heart was no longer to be heard beating. Artificial respiration was continued for twenty minutes longer, although with little hope of success. Micturition had taken place after the beginning of the administration of the gas, and the author remarks that he

has not infrequently noticed this occurrence when cyanosis has been well marked, also in children. At the necropsy, performed at the request of the coroner, the body was found to be that of a man about twenty-six years old, muscular and well nourished. The face, neck, and back were deeply cyanosed. On removing the skull-cap, venous engorgement was visible on the surface of the cerebral hemispheres, but nothing abnormal was noticed in the substance of the brain. On opening the chest, the veins were seen to be everywhere full of dark fluid blood. All the internal organs were healthy. The pericardium contained a normal amount of fluid. The heart was normal and the valves were competent. All the cavities of the heart were empty, except that there was a small quantity of fluid blood in the right ventricle. There were no clots. The lungs were engorged with dark fluid blood and were nearly destitute of air. On opening the bronchi, the mucous membrane was found dark-colored and engorged, and a quantity of thick mucus was revealed in all the larger bronchi. The trachea also was engorged, but contained less mucus. The larynx showed no swelling and very little engorgement, and contained no appreciable quantity of mucus. There was no foreign body or any abnormal substance. The tonsils showed chronic enlargement, but they did not meet. The stomach contained a small

The author states that he has administered nitrous-oxide gas to over forty thousand patients during the last twenty years, and has never before had a fatal case. It seems to him that the patient died from asphyxia, and he thinks that the mucous membrane of the throat, larynx, and bronchi was perhaps peculiarly insensitive, for during the whole time of the administration of the gas, and subsequently, there was no coughing or symptom of irritation, as is often the case when a quantity of mucus gets into the air-passages. As regards the quality of the gas, two patients had immediately before had it given to them from the same receptacle, without the slightest unusual symptoms, and it was used on the following day with good results.

quantity of undigested food, with a good deal of ropy mucus.

The œsophagus was normal. The liver, kidneys, and spleen

were dark-colored with venous engorgement, but showed no

signs of disease. The bladder was empty.

**Diuretin and Diuretics.**—The *Hospital* for March 3d publishes a paper by Sir Benjamin Ward Richardson, M. D., F. R. S., in which he says:

"My first observations were made, if I may so say, casually -that is, I began to prescribe diuretin in small, increasing, and large doses in cases where a diuretic was supposed to be required, without special reference to cause. The first few administrations gave color to the idea that diuretin possesses the general powers claimed for it; but I soon found great variability in regard to its action, and was led to the conclusion to which Dr. H. A. Hare had arrived, that the greatest care must be taken in observation, in order that other agencies affecting the excretion of urine should not interfere with the correctness of the observer. It also seemed to me that in some instances symptoms followed the administration of the drug which were of a general kind, such as headache, depression, a little fever, somnolency, or slight delirium, symptoms which were not actually dangerous or alarming in degree, but which were inconvenient and which called for cessation of the administration, at least temporarily.

"I never witnessed, however, the symptoms of vomiting and diarrhea which some have observed as after effects, and I considered that there was no direct evidence of cumulative action such as is observed from digitalis. Altogether, I looked upon diuretin as being a diuretic under some circumstances, but as

one rather uncertain in its effects. In order, therefore, to watch those effects in a more systematic way, I noted them carefully in one or two particular cases where other diuretics had been prescribed.

"A man, sixty-two years of age, came under my care in hospital on July 9, 1892. He weighed two hundred and ten pounds and stood six feet two inches in height. He had been a night watchman and had remained at his occupation almost up to the date of his admission. He complained of great pain in his right side, and, on careful examination, was found to have a considerable effusion in the right pleural cavity, with probably some ascites. It was observed that he suffered from shortness of breath, especially at night, and a day or two after admission eighty-eight fluidounces of a clear serous fluid was removed from the chest by aspiration. The removal gave immediate relief, but the fluid soon reaccumulated, and three weeks later a hundred and twenty-four ounces were drawn off. Fluid also was collecting in the abdomen, and, to be brief, between August 17, 1892, and May 20, 1893, when the patient was discharged to go to a home, he had been tapped seven times in the thorax, fourteen times in the abdomen, and twice -by Southey's tubes-in the lower limbs, by which operations six hundred and thirty-two ounces were drawn off from the chest, three thousand and eighty-nine ounces from the abdomen, and two hundred and seventy-two from the lower limbs-in all, twenty-four gallons, three quarts, one pint, and thirteen fluidounces. He was greatly relieved each time by the removal of fluid, and, as his heart was natural, our diagnosis was chronic nephritis, with cirrhosis or chronic contraction of the kidneys. There was never any febrile state, but, on the contrary, a slightly subnormal temperature as a rule. He took his food well, and up to his discharge was in good spirits.

"As may be expected we did our best in this case to promote action of the kidney. There was no regular appearance of albumin in the urine, but the amount of urine secreted was at all times diminished, often to an extreme degree, so that some days fourteen ounces was the most passed, during which the reaccumulation of fluid in the abdomen and chest was rapidly increased, as if these cavities became supplementary receptacles for the water that ought to have passed off through its natural channel. In the course of general treatment the patient was, of course, judiciously limited as to the amount of watery fluids which he imbibed, and I think I may say every reasonable form of diuretic was administered to him without giving him any relief and without increasing in the least degree the quantity of the excretion. The case thus became one singularly good for testing the value of diuretin as a diuretic, and on March 17, 1893, diuretin was administered in five-grain doses, which were continued for three days without striking effect. The dose was then gradually increased to ten grains with such good action that after administration three times in the twenty-four hours seventy-five ounces of urine were discharged. Free diuresis was maintained for several days, when it gradually failed, with the appearance of symptoms which forbade the continuance of the drug. There was headache, considerable depression, undue somnolency, and a rise of temperature-symptoms which passed away within twenty-four hours on the discontinuance of the remedy. After the lapse of a few days, the amount of urine having become greatly diminished, I represcribed the diuretin in ten grain doses without any definite action, but with recurrence of the objectionable general symp-

"In this instance diuretin failed to sustain free diuretic action and induced systemic symptoms similar to those which follow the administration of soda salicylate and sometimes salicylic acid, but without the deafness or noises in the head which occasionally follow the action of these drugs when they are carried to a toxic degree.

"The action of the diuretin in the case given was, I should assume, on the renal epithelium, leading in the end to obstruction, with an after effect on the nervous system produced either by the salt itself or by retention of urea, or a combination of both effects. That the action was not cumulative is shown by the fact that the symptoms quickly ceased when the substance causing them was withdrawn."

The Merritt H. Cash Prize. - The secretary of the Medical Society of the State of New York, Dr. F. C. Curtis, has issued a circular stating that the Medical Society of the State of New York offers a prize of one bundred dollars, payable from the Merritt H. Cash Prize Fund, for the best original essay on any medical or surgical subject. The conditions are: That the competitor shall reside in the State of New York and shall be a member of a county medical society; that the essay shall be either printed or type-written; that each essay shall be designated by a motto on the title-page and accompanied by a sealed paper bearing the same motto and inclosing the name of its author, in order that the name of the successful author alone may be ascertained; and that all essays shall be sent to the chairman of the committee on prize essays prior to January 1st, next. The committee consists of Dr. Franklin Townsend, Jr., 2 Park Place, Albany; Dr. A. Walter Suiter, Herkimer; and Dr. Charles Stover, Amsterdam. Secretaries of county medical societies are requested to communicate this to the members of their societies.

Salacetol.—The Nouveaux remèdes for March 8th contains the following résumé of an article by MM. Bourget and L. Barbey, published in the Therapeutische Monatshefte for December, 1893: Salacetol—

OH.

## COO.CHaCO.CHa

is obtained by heating monochloracetone with salicylate of sodium. It crystallizes in alcohol or ligroin in the form of scales or brilliant needles. It is slightly soluble in hot or cold water, and dissolves in hot alcohol, ether, carbon sulphide, chloroform, benzol, ligroin, etc. It has a slightly bitter taste, and melts at 160° F. Shaken up with an alkaline liquid, for example, a 0·6-per-cent. solution of caustic soda, it is dissolved and saponified—that is, it becomes split up into its component parts.

It is known that under the influence of intestinal alkalinity salol is split up into salicylic acid and phenol. Salicylic acid combines with alkaline substances (salicylate of sodium or potassium) and gives compounds which are destitute of any antiseptic action; in its nascent state, and before it is combined with alkalies, it is supposed to be a very energetic antiseptic. As for phenol, which is very poisonous, it gives the sulphocarbolates of sodium or potassium, which are not poisonous at all. This combination is due to the action of the liver, and perhaps also to that of the intestinal mucus; it does not occur except where there is a sufficient quantity of alkaline sulphides. Salacetol, therefore, should always be administered simultaneously with a certain quantity of sulphate of sodium. The latter may also be employed as an antidote to phenol. In this respect salacetol is superior to salol, as the former becomes split up in the intestine into salicylic acid and acetol. The latter is eliminated by the urine in the form of acetone, or oxidizes in its elements without injury to the organism, and without exacting from the liver such an amount of work as to irritate or overtax it. Salacetol passes through the stomach almost unchanged, without undergoing the least modification. Passing

into the intestine, it becomes split up into acetol and salicylic acid. The latter is rapidly resorbed, the urine showing traces of salicylic acid in a quarter of an hour after the administration of fifteen grains of salacetol. Castor oil accelerates the resorption of salacetol. When it is given in the form of a powder, in a dose of thirty grains, from eight to nine grains of salicylic acid are found in the urine twenty-four hours afterward, but if it is given dissolved in four hundred and fifty grains of castor oil, at the end of twenty-four hours from twelve to thirteen grains are found. The causes for this more rapid resorption are, on the one hand, the slightly irritating action of castor oil, which gives rise to a more abundant secretion of the intestinal juice, consequently splitting up the salacetol in a more energetic manner, and, on the other hand, the intestinal peristalsis is rendered more active. Dilatation of the stomach does not influence the resorption of salacetol in any way. This resorption depending upon the intestinal alkalinity, it is easy to understand that it would be retarded by the pouring of a large quantity of acid gastric juice into the intestine. In this event, the intestinal juice, before coming in contact with salacetol, would necessarily have previously neutralized this gastric juice

The cutaneous absorption of salacetol depends upon the substance in which it is incorporated. Salacetolized vaseline is not absorbed at all, while salicylic acid may be found in the urine from three to four hours after friction with salacetolized lard. Salacetolized lard with ten per cent. of oil of turpentine, and a solution of salacetol and chloroform in which lard and a small quantity of lanolin have been incorporated, are also completely resorbed.

Salacetol is an excellent antiseptic for the intestinal cavity. Given for two days in doses of from thirty to forty-five grains, dissolved in from three hundred to four hundred and fifty grains of castor oil, it has produced good results in cholerate diarrhea. The intestine is disinfected as early as the third day. If the diarrhea continues, the same dose is repeated. At the beginning of the third day salacetol alone is prescribed in daily doses of from thirty to forty-five grains. Children can take a grain and a half of salacetol for each year of their age.

In acute articular rheumatism the administration of thirty grains is followed in two or three hours by a falling of the temperature and lessening of the pain. If this dose is repeated from two to four times a day, the temperature becomes normal, and convalescence sets in as early as on the fourth or fifth day. The following ointment is recommended by MM. Bourget and Barbey for diseased joints: Salicylic acid, oil of turpentine, and lanolin, each, a hundred and fifty grains; lard, fifteen hundred grains. Salacetol also is prescribed in doses of fifteen grains, given morning and evening. They have obtained excellent results with this treatment. Muscular and chronic rheumatism have also been treated successfully with salacetol, and favorable results have been observed in cases of biliary lithiasis from the use of this medicament dissolved in castor oil. In these cases thirty grains of salacetol, dissolved in almond oil or (especially in winter) in cod-liver oil, were given every day for three or four weeks. On the whole, salacetol may replace with advantage all other salicylized preparations, and its employment is especially recommended for children.

The American Medical Association.—The committee of arrangements has issued a circular announcing that the rates have been reduced to sixty dollars for a round-trip ticket from the Missouri River points to San Francisco, and that the same reduction will be made between the Missouri River and Chicago and between Chicago and the Atlantic points, practically making the round trip a single fare.

## Rectures and Addresses.

### LECTURES ON THE DIAGNOSIS OF ABDOMINAL TUMORS.

BY WILLIAM OSLER, M. D., PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY.

LECTURE IV .- TUMORS OF THE GALL BLADDER.\*

THE gall bladder may be dilated or its walls infiltrated with a new growth. In a large proportion of all cases these conditions are associated with gallstones. Of six cases in which the gall bladder presented either tumor or enlargement, three were due to gallstones, one to compression of the common duct by malignant disease, and in two the walls were infiltrated with cancer.

(a) DILATED GALL BLADDER.—The organ may form a small, firm, rounded projection beneath the edge of the liver, a pyriform tumor of varying size and freely movable, in exceptional cases a very large tumor reaching to the pelvis, or, indeed, as in a case reported by Tait, a huge cyst occupying the greater part of the abdominal cavity. The usual causes of dilatation are blocking the ducts with calculi and compression of them by new growths. The greatest dilatation is associated with obstruction of the cystic duct. Permanent blocking of the common duct does not necessarily lead to very great distention of the gall bladder. The contents of the dilated organ may be a clear mucoid fluid when the obstruction is in the cystic duct and very prolonged; bile most frequently when the obstruction is in the common duct; pus or a puriform bile-stained fluid when suppuration has occurred, and an albuminous or bloody fluid in cancer of the walls. I will first read to you the cases in which the gall bladder formed a prominent tumor. Two of these were associated with gallstones and one with obstruction of the common duct by cancer. The diagnosis, which seemed perfectly clear, was confirmed in one case by operation and in another by autopsy. But before I do so let me call your attention to two monographs, the most important contributions to the literature of cholelithiasis which have been made for some years. Professor Naunyn's work, Klinik der Cholelithiasis, deals particularly with ætiology and symptomatology, while that of Professor Riedel, Erfahrungen über die Gallensteinkrankheit, mit und ohne Icterus, is of very special value to workers in clinical medicine, and illustrates in an interesting way the close interdependence of medicine and surgery. His careful study of an extensive series of cases upon which he had operated enlarges in certain directions our knowledge of the symptomatology of gallstones, more particularly of the cases without jaundice.

Case XXXVI. Gall Bladder forming a Visible Tumor; Operation; Recovery.-Elizabeth D., Lonaconing, Alleghany County, Md., aged sixty-two years, seen with Dr. Kelly. She had been married thirty-eight years; had six children; three miscarriages; labors non-instrumental, but tedious.

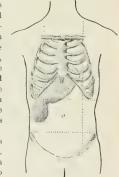

\* Delivered December 6th.

Family history good. Has always been well until the present trouble. In December, 1891, she fell against the curbstone and struck the right side. At the time she felt very little pain, but remarked that she had had a great "shaking up." Some time in January, she does not know exactly when, she noticed a lump in the abdomen which changed in position as she moved in bed. It has not, she says, got any larger since January. Five weeks ago she one night became jaundiced. She is positive that the skin was clear one day and the next morning pretty deeply jaundiced. The stools were clay-colored, and remain so. Since then the bowels have been at times loose, sometimes three or four in a day. The urine became highcolored; the skin has been itchy, and the pulse rate very slow. She has lost somewhat in weight; she has had no chills, no fever, and no sweating.

Present Condition .- Large, well-nourished woman; the skin of an orange-green color; tongue clean; pulse, 32; temperature normal. The abdomen is enlarged and flabby. On the right side, midway between the costal margin and Poupart's ligament, there is to be seen a hemispherical prominence, which moves up and down with respiration. On palpation the abdomen is everywhere soft, not painful. The liver can be felt in the epigastric, right umbilical, and right hypochondriac regions, firm and resistant, and in the middle line the margin can be felt about two fingers' breadth above the navel. In the right parasternal line a distinct notch can be felt, the separation probably between the right and left lobes. In the nipple line the edge reaches to the level of the navel and in the anterior axillary line nearly to the level of the anterior superior spine. The prominent mass which is seen with such distinct-

ness can be felt a hand's breadth below the liver margin; it is smooth, rounded, resistant, and as the fingers are pushed beneath it there is the impression of a globular body. It can be freely moved from side to side, and changes in position as she turns to the left. The dotted line in the diagram indicates the position when she rolled over on the left side; the fundus of the gall bladder then almost reaches the middle line.

The surface of the liver is smooth. There are no nodules. On deep inspiration the spleen can not be felt; there are no glandular enlargements. There Fig. 30,-Showing the position of is a systolic murmur at the apex of the heart, but the sounds are

the gall bladder in Case XXXVI.

clear at the base. The stools are clay-colored; the urine contains much bile pigment.

November 7th .- This morning Dr. Kelly made an incision fifteen centimetres long over the tumor. On opening the peritoneal cavity the liver looked of a dark greenish-brown color. Projecting beneath the edge of the right lobe for a distance of about five centimetres was the rounded end of a dilated gall bladder. The liver substance above it was considerably atrophied. There were no adhesions. The chief bulk of the dilatation was beneath the liver, and the dilatation was much greater than indicated by the portion which could be felt projecting beyond the edge. One hundred and fifty cubic centimetres of turbid, grayish pus were removed with the aspirator. Calculi could be felt in the cystic duct and at the first portion of the common duct. After aspiration the gall bladder was carefully stitched to the external wound and incised and a large gall stone removed weighing thirty-eight grammes. The stone occupied the cystic duct and projected into the common duct.

The points of interest in connection with this case are, in the first place, the easy diagnosis of dilated gall bladder on account of the position and character of the tumor. It seemed most likely, too, that the dilatation and the jaundice were due to gallstones, though she had never had attacks of biliary colic. In all probability the cystic duct was blocked by the large stone as early as December, when she fell against the curbstone; she is positive that the lump on the right side has been present ever since that time. The sudden onset of the jaundice five weeks ago was connected doubtless either with the moving of the stone into the common duct or the extension of inflammation from the cystic duct to it; most probably the former.

A second point of great interest in the case is the existence of an empyema of the gall bladder without chills or fever. In all probability the suppurative process was confined to the gall bladder and had not extended to the general bile passages, associated with which, so far as I know, there is invariably fever of a septic type.

The patient did very well. Much bile-stained material escaped from the wound, the jaundice became distinctly lighter, and bile appeared in the fæces. By the 14th of November the skin was much less yellow, the urine lighter in color, and the itching of the skin had entirely ceased. She improved rapidly, sat up by November 21st, and was discharged on December 14, 1892.

Case XXXVII. Attacks of Gallstone Colic; Tumor of Gall Bladder.—Miss S., aged about forty-eight years, seen with Dr. Ames, June 16, 1893, complaining of swelling and pain in the abdomen. Patient has been delicate from childhood, and has been for years a chronic invalid.

When about ten years of age she had a severe illness and for some time could take no nourishment without severe abdominal pain. Dr. Buckler thought that it was possibly ulceration of the stomach. When twenty years of age she had a similar illness-evidently protracted, painful dyspepsia. When thirty-five years old she had a severe attack of liver colic, in which she changed color and was slightly jaundiced. She has had since that time many attacks of pain, particularly at night, after a very trying or exhausting day. At forty-three the menopause began, following which she had a nervous breakdown and went to Italy, and for a couple of years she had a great deal of intestinal trouble. After returning, on September 6th of last year, she had a very severe attack of colic and was extremely weak. These attacks of colic have occurred throughout the winter and the last one she had was only a few weeks ago.

Present Condition.—Small-framed woman, looks ill, very anæmic and sallow; no definite jaundice; no special emaciation. Pulse 92; tension a little increased.

Abdomen flat, natural-looking. Palpation is everywhere negative until one reaches the liver region. Here inside the nipple line there is a definite rounded projection, the outlines of which can be readily determined, particularly below and to the left. It projects as a somewhat conical mass and is rounded at the right border. It is a little painful on deep pressure. The fingers can not be inserted definitely beneath it, but on either side the edge of the liver is distinct; as she draws a

deep breath the fingers seem to pass over a prominence into a depression on the surface of the liver just at the level of the

costal margin. During the attacks the projection, as she calls it, forms a prominent tumor which can be seen beneath the skin and is then exquisitely sensitive. The liver duliness extends to the upper border of the sixth rib. The right kidney is distinctly palpable and descends below the edge of the liver, from which it can be readily separated.

At a subsequent examination the tumor was not nearly so large, and she insists that it is extremely variable in size. Whenever the colic is severe the tumor becomes very much more prominent, a point confirmed repeatedly by Dr. Ames. She is excessively anamic, and though anxious for an operation, it was thought best to nost

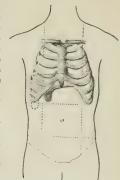

Fig. 31.—Showing the position of the gall bladder and outline of the right kidney.

tion, it was thought best to postpone it until the condition of her blood was more satisfactory.

Additional Note - The tumor mass in the epigastrium developed considerably and became very much firmer, reaching almost to the level of the navel. The patient herself said that it had undergone a change, and she had a good deal of pain at intervals. She was very urgent that an operation should be performed, and, as her general condition seemed fairly good, Dr. Tiffany, on January 9th, made an exploratory incision. The gall bladder projected between two and three inches below the margin of the liver. A coil of the small intestine, and also the transverse colon, were firmly adherent to it, and over its surface there was a definite vascular membrane. There were numerous adhesions between the upper surface of the liver and the diaphragm. The gall bladder felt firm, and at its fundus there was a nodular mass. When it was opened a bile-stained mucus exuded and the whole organ appeared filled with a semisolid, friable, grayish-yellow mass. Fragments removed with a curette, particularly the scrapings of the wall, had a grayishwhite appearance, and looked like a new growth. On microscopical examination they consisted of large, irregular cells, many of which were in a state of fatty degeneration.

After doing well for three or four days the patient began to complain very much of pain in the lower part of the abdomen. There was no swelling, and until the evening of the 14th there was no fever. On the 15th the pulse was more rapid, and she seemed very much weaker. She was worried about not having had an action of the bowels, and was a good deal exhausted in an attempt to get them relieved. About one o'clock she became feebler, gradually sank into a condition of unconsciousness, and died about 5.30 in the afternoon.

Autopsy, Jan. 16.—The wound of the skin and the incision in the gall bladder had both united well. After turning back the skin flaps, the intestines were found to cover the gall bladder everywhere, except at a small area just below the liver margin in the nipple line. The portion of the right lobe of the liver adjacent to it was considerably elongated, and consisted of a grayish-white atrophic tissue. The stomach was distended and the duodenum was pushed forward and much dilated with gas. It was opened in situ, and its posterior wall found to be in close contact with the gall bladder. The bile papilla, which was in the transverse portion of the duodenum, was not oc-

cluded. After dissecting off the duodenum the tumor beneath it was seen to be the greatly distended gall bladder, somewhat larger than a closed fist. It was deeply placed, lifted the head of the pancreas and the duodenum, as already mentioned, and was in contact with the right side of the vertebral column. It was readily and freely lifted from its bed, and then was seen to project about eight centimetres below the liver margin. The transverse colon was adherent to it, and just at the point of their union there was a nodule of new growth of the size of an English walnut. On incising the gall bladder, a small quantity of turbid bile exuded, but the entire viscus was occupied by a globular new growth, which was everywhere free, except at the upper wall, where it was densely adherent and had grown into the substance of the right lobe. It did not extend to the neck of the gall bladder, and the orifice of the cystic duct was free.

On section, the mass consisted of a fresh, grayish neoplasm, on its surface much bile-stained. There were six or eight small black, irregular gallstones. There were no secondary nodules in the liver. The common duct was free. The stomach and intestines looked normal. There was a small cyst of the left parovarium, which was united to the rectum by old, firm adhesions.

Case XXXVIII, Enlarged Gall Bladder; Jaundice; Cancer of the Head of the Pancreas .- Mr. M., aged fifty-one years, seen April 26, 1893, with Dr. W. W. Johnston. The patient is a large man, very active in business, and with an excellent family and personal history. He had a slight attack of jaundice during the civil war. Has not been a heavy drinker. Was well and strong until toward the end of last year. He had a mental shock and worry in October which distressed and disturbed him a good deal, and he had dyspepsia on one or two occasions before Christmas. Early in January he had a very severe attack with vomiting, and then began to lose in weight and had uneasy sensations in the epigastric region, but no sharp, acute pain. About the middle of January he noticed that he was yellow in color, and the jaundice, increasing in intensity, has been permanent. The stools have been clay-colored; the urine very much bile-tinged. He has had no itching, nor has the pulse ever been slow. He has lost progressively in weight, thinks as much as forty or fifty pounds, and has become very weak, though he has kept up and about and until two weeks ago has attended to his business.

Present Condition.—Intense olive-green jaundice; moderate emaciation; pulse, 82; fair volume; moderate tension; vessel not sclerosed.

Abdomen prominent, and percussion and palpation demonstrate the existence of moderate ascites, which, Dr. Johnston says, has not materially changed for several weeks. On palpation, no pain, nothing abnormal to be felt until toward the right costal margin, below which the liver extends for about an inch and a half in the parasternal line. In the anterior axillary line, about two inches in front of the cartilage of the tenth rib, there is a firm, rounded, nodular body the size of the top of a lemon, which is attached to the liver and projects definitely beyond its edge. It feels like a distended gall bladder, but it is unusually hard, firm, and inelastic, and it is not movable from side to side. On deep inspiration, the surface of the liver above it can be felt to be distinctly depressed. In the parasternal line the edge of the liver is irregular, and there appear to be one or two nodules. In the middle line, on deep inspiration, the surface of the left lobe also appears rough and irregular. The spleen is not palpable. The stomach does not appear to be dilated. Examination of the thoracic organs is negative.

Patient died May 7, 1893. The autopsy showed cancer of the pancreas, with secondary nodules in the liver. The gall bladder was greatly distended and projected beyond the edge

of the liver, and formed the tumor which had been so plainly to be felt during life, measured about six inches in length and about three inches in diameter, and was full of a light-greenish fluid. The walls were not indurated.

In the diagnosis of the tumor caused by dilatation of the gall bladder there are details to which I may here refer. The patient should be recumbent, in a perfectly easy posture, with the abdominal walls as much relaxed as possible. Sometimes, as in Case XXXVI, a prominent tumor is at once visible, descending with inspiration, or there may be a swelling of considerable size in the right half of the abdomen. More frequently, however, inspection is negative, and the facts must be elicited by careful palpation. The facility with which this procedure can be carried out depends upon the degree of rigidity of the abdominal walls, and a thorough examination may be impossible without anæsthetizing the patient. Bimanual palpation is the most satisfactory. Sitting by the side of the patient, the left hand beneath the lower ribs, with the right upon the abdomen, a little below the costal margin in the nipple line, gentle palpation with the pads of the fingers is first made during quiet breathing. The patient is then asked to draw a deep breath, and gentle but firm palpation is repeated, the fingers of the right hand following the receding abdominal walls. The anterior edge of a normal liver can in this way be readily felt, and any marked projection of the gall bladder detected. On the whole, I think you will find it more satisfactory to use the fingers of the right hand for palpation, but it is possible also to use the thumb of the left hand in the method described by Glénard, his procédé du pouce. The left hand grasps the right flank with the fingers behind. With the thumb, which is then free, the edge and surface of the anterior part of the right lobe of the liver can be readily felt, as the organ descends during inspiration. The facility with which this procedure can be carried out depends somewhat upon the length and mobility of the thumb.

Situation and General Characters.-The position varies with the size of the tumor and the existence of enlargement of the liver. Moderately distended in a liver of normal size, the gall bladder may be felt projecting beneath the costal margin opposite the end of the tenth costal cartilage. It is superficial, appearing to lie immediately beneath the abdominal wall. The long axis may be parallel with the nipple line. More frequently, however, the direction is somewhat to the left, as indicated by Fig. 31. The tumor is usually to the right of the parasternal line, but it may be directly in or even to the right of the nipple line, while in other instances it may be chiefly to the left of the parasternal line. The fingers may be placed directly beneath it, and the sensation given is that of a smooth, rounded body, larger at the lower end than above-that is, pearshaped. While the outlines below are usually readily defined, toward the liver they are obscure, and no definite edge can be felt above the tumor. This is a point of importance in the differentiation of floating kidney. Sometimes the tumor appears to be turned forward on its axis, like a gourd, and a groove may be felt separating it from the liver. As a rule, palpation is not accompanied with much pain. The sensation conveyed to the finger is usually that of a tense, firm, elastic body. This is not always the case, for an enlarged gall bladder may be extremely flabby and soft, and is then difficult to feel. On the other hand, it is to be remembered that in long-standing cases of cholelithiasis there may be complete calcification of the walls of the gall bladder, forming a tumor of stony consistence. The size of the tumor projecting beyond the liver margin is some measure of the degree of distention of the gall bladder, particularly when the dilatation is due to plugging of the cystic duct. When the common duct is obstructed there may be great dilatation of the gall bladder and ducts with only a slight tumor projecting beyond the costal margin. I have reported a case, operated upon by the late Dr. Agnew, in which the fundus of the gall bladder projected only 2.5 centimetres, but on lifting up the liver it was seen that the distention was chiefly beneath the margin, and eighteen ounces of bile were removed by aspiration. While these statements hold for moderate dilatation of the gall bladder, you must remember that there are instances on record in which the tumor is exceptionally large, extending to the pelvis, occupying the entire right side, or even filling the abdominal cavity like a large ovarian cyst.

You will have noticed in the reading of the report of Case XXXVI that the tumor was extremely mobile and that the patient herself noticed its variability, and, projecting as it did so plainly, the alterations in position could be seen. The mobility during respiration is also well marked and it may be seen to descend with inspiration. On palpation the tumor may be moved freely from side to side. On the deepest inspiration, however, it can not be grasped and held in position as is possible with an extremely mobile kidney.

Nature of the Contents.—In a doubtful case of tumor projecting below the right costal border aspiration may be practiced, using a fine needle and exercising caution that the bowel does not lie between the tumor and the abdominal wall. The contents of a dilated gall bladder are either clear mucus, which is most common in prolonged obstruction of the cystic duct; bile, when the common duct is blocked, though when occluded for a prolonged period the entire bile passages, including the gall bladder, may be filled with a thin mucus. Pus is met with frequently, usually general symptoms indicating that suppuration has occurred; and, lastly, blood may be present in cases of neoplasm of the gall bladder. In acute phlegmonous inflammation due to calculus, the gall bladder may contain a dirty, brownish-red, ill-smelling fluid.

From growths at the pylorus and in the colon, which may occupy a similar position, the gall-bladder tumor is, as a rule, readily distinguished, both by the differences in the symptoms, and particularly by the systematic local examination, using also the inflation of the stomach and intestine. To two conditions I would, however, call your attention. In stout persons, and when the abdominal walls are unusually tense, movable kidney on the right side may be mistaken for an enlarged gall bladder. Only, however, when the kidney is very movable does it descend so low and so far to the left that this mistake could

occur. It does sometimes, however, emerge beneath the liver margin as a rounded tumor in a most deceptive manner. With the patient recumbent and the kidney in its natural position, no tumor is evident; but on change of position (turning to left) or on deep inspiration it then appears. A movable kidney on the deepest inspiration, with the fingers placed above it, can be held down and prevented from returning during the expiratory movement. A gall bladder tumor rises and falls with the respiratory movements, and can not be held down during expiration. Again, above the rounded surface of the kidney, the sharp margin of the liver may be felt with great distinctness, whereas in gall bladder tumor the upper limit is not to be defined, and there is no sharp edge above it.

An interesting anatomical condition of the liver which you must learn to recognize has been referred to—particularly by Professor Riedel—namely, a tongue-shaped process of the anterior margin. A knowledge of its existence may save you from error. I show you here the outline as given by him in one of his cases (Fig. 33). He believes that this extension is seen particularly in women whose livers have suffered from the effects of lacing, but it is directly caused by traction, the gradually distending gall bladder elongating the anterior margin. In twelve of the cases upon which Riedel operated this tongue-

like process was present; in nine instances the gall bladder was palpable either at the median or under margin of the process. In Case XXXVIII I believe this process is present. It is not always, however, associated with dilated gall bladder, and I have seen very curious elongations of the anterior margin of the right lobe in perfectly normal livers, and in several instances of the posterior margin of the left lobe. It is important to recognize the existence of this process as it may form a very definite mass in the right flank. A very interesting instance of it was re-

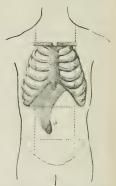

Fig. 32.—The tongue-shaped extension of the anterior margin of the right lobe, with the gall bladder projecting below it. (Riedel.)

ferred to me by Dr. Weir Mitchell two years ago. An extremely nervous woman, aged about fifty-six years, had had for several years symptoms of neurasthenia, pains in the abdomen, and ill-defined manifestations, for which she had sought relief in many quarters. In his note to me Dr. Mitchell stated that there was a tumor of doubtful nature in the right flank. I saw the patient with her relative, Dr. Tilghman. The only interest in the case is in the examination of the abdomen. Just beneath the right costal margin, extending toward the anterior superior spine, was an elongated mass with very ill-defined borders. The fingers could not be inserted beneath it, nor was there a definite edge palpable. It was tender on pressure, not movable in a lateral direction, but with the fingers deep in the flank

behind it could be tilted forward. It did not seem to be continuous with the liver, the dullness of which terminated just below the costal margin. It descended somewhat with the respiratory movements. The right kidney was not palpable. Altogether I was puzzled by the condition, and could not give a positive opinion as to the nature of the trouble. She had a good deal of abdominal pain and distress, most of which I thought was associated with nervous dyspepsia. As there had been some uterine trouble I suggested that the pelvic organs should be examined. Subsequently, she came under the care of my colleague, Dr. Kelly, who at once discovered the tumor in the abdomen and, with the advantage pertaining to surgery, he very quickly determined by laparotomy the nature of the tumor-namely, an elongation from the right lobe of the liver. He writes: "There was no visceral trouble, excepting the enormously elongated thinned-out lobe of the liver, which extended down on the right side at least four inches below the normal position, and seemed to be an elongation of the anterior margin. The gall bladder was not enlarged." \*

(b) Cases with Ill-defined Nodular Tumor at Liver Edge, supposed to be Gall Bladder.—While the presence of a well defined tumor is of the utmost importance in the diagnosis of gall bladder disease, there are cases in which we have to be content with less positive evidence. A special value of Professor Riedel's work in relation to the diagnosis of gallstones lies in a somewhat startling revision of accepted data regarding the cardinal symptoms of this disease. Thus, ten of the fifty cases upon which he operated had never had colic; only fourteen presented a definite tumor, and a majority had never had jaundice.

The following cases are of interest from the fact that a small nodular tumor was felt in both, not very clearly defined; in one the history of severe and protracted attacks of colic seemed clearly to indicate the presence of gallstones, while in the other case the condition was more doubtful.

Case XXXIX. Severe Attacks of Colic for Five Years; Nodular Tumor at Edge of Liver; Operation with Removal of Three Hundred Gallstones.—August W., aged forty-two years, seen April 28, 1893. Sent by Dr. Salzer.

Patient is a large-framed, well-built man; has always enjoyed excellent health, with the exception of malaria twelve or thirteen years ago. Has always had a very good appetite and has been a heavy eater. He has not been a dyspeptic, but has been troubled at times with constipation, but until the onset of his present illness he always regarded himself as a very healthy man.

He comes complaining of attacks of severe and protracted pain in the abdomen, which began five years ago. While walking in the garden one evening he had severe colicky pains, like cramps, which lasted throughout the greater part of the night; he was not jaundiced and the attack was regarded as one of simple colic. Six months afterward he had a second and more severe attack, which came on suddenly in the same way. Sub-

sequently the attacks became more frequent, and he had at least six or seven in the second year, and they have gradually increased until be has been rarely a month or six weeks without pain. He has only once had vomiting with the pains, and never brought up any blood; has never had diarrhea, most frequently has been constipated. The pain begins as a rule in the upper abdomen, radiates to the back, and sometimes is very diffuse throughout the back and sides. Its duration varies extremely; thus, the day before yesterday he had a severe attack; yesterday he was free from pain. In a bad attack he is quite incapacitated, and can not straighten himself to walk. He never has had bloody urine after the attacks, and never has passed gravel. The early part of this winter the colic was very severe and he lost considerably in weight. I could get no history of jaundice from the patient or from his wife, but Dr. Salzer informs me that at least twice icterus followed the attacks of severe pain.

Present Condition.—Face is flushed; color good; venules of cheeks a little dilated; conjunctive not stained.

Abdomen is full; panniculus well preserved; on palpation everywhere soft. In nipple line, three fingers' breadth below costal margin, he winces on pressure, and here is to be felt an irregularity at the edge of the liver. In middle line the edge is indefinite; in parasternal line the liver can be felt about two fingers' breadth below margin, and there is an ill-defined, rounded, somewhat nodular mass in this situation, which moves with respiration. It is sensitive on deep pressure. Liver dullness begins at the seventh rib and extends to the costal margin in parasternal, and a finger's breadth below in nipple line.

The edge of the spleen is not palpable, but dullness extends from the eighth to the eleventh ribs in midaxillary line.

The stomach is not dilated; thoracic organs negative.

The diagnosis of gallstones was made and he was advised to

have an operation.

May 4th.—Dr. Halsted opened the abdomen and explored the gall bladder. It was found that the irregular mass at the edge of the liver was due to a marked projection of the anterior border. It was not to the left of the notch of the gall bladder and did not form a definite tonguelike extension, but was rather an irregular projection of the border. There were numerous adhesions between the under surface of the liver and the colon. The gall bladder did not look enlarged. It was laid open and found to contain a clear mucoid fluid and about three hundred gallstones of various sizes, chiefly very small, but one at the orifice of the cystic duct was the size of a small cherry. The patient reacted well from the operation, had no fever, and made a satisfactory recovery.

In the following case, led astray by a nodular prominence at the edge of the liver, I thought the condition was possibly gallstones in the common duct; but unfortunately the exploratory laparotomy did not give us any definite information.

Case XL. Enlarged Liver; Nodular Tumor at Margin; thought to be the Fundus of Gall Bladder.—Henry L., ag.d thirty-three years, traveler for a spirit house, was admitted November 1, 1892, complaining of jaundice.

Father died at sixty years of paralysis; mother and seven brothers and sisters living and well.

Patient has always been well and strong. The only serious disease was diphtheria at his fifteenth year. Patient has been a pretty steady drinker, chiefly of beer; has had gonorrhea, and was under treatment many years ago for syphilis, the constitutional symptoms of which were very slight. He has never had hæmorrhoids.

<sup>\*</sup>Those interested in the subject may consult with advantage Hertz's recent work, Abnormitation in der Lage und Form der Bauchargame bei dem erwachsenen Weibe, eine Folge des Schnuren und Hampbauchus.

He has not been feeling very well for a year or more, and has been depressed in spirits owing to domestic troubles. He has been at work until a month ago. The present illness began two months ago, when he noticed that he was gradually getting yellow. There were no pains at the outset; no colic; nor had he nausea or vomiting. The appetite was good; the bowels were regular, and he did not feel badly enough to stop work for more than a month after the jaundice appeared. He had at times a sense of weight and dragging in the liver region, but never any pain. He has lost gradually about twenty pounds in weight within the past few months.

Present Condition.—Patient is a well-built, spare man; not specially emaciated; skin and conjunctive of a tolerably intense lyellow color. The temperature is normal; pulse 64, full, reguar; tension a little increased and the vessel wall slightly thickened. Thorax is barrel-shaped; resonance everywhere clear; no adventitious sounds. The heart beat is in the normal position; the sounds are clear, and the second, at the aortic cartilage, is decidedly accentuated.

Abdomen is enlarged, particularly in the upper zone, and is prominent in the right hypochondriac region. On palpation the whole of the right hypochondriac and epigastric, and part of the umbilical regions are occupied by a firm, resistant mass, corresponding to an enlarged liver. The lower border extends to within about three centimetres of the umbilicus and passes under the right costal margin at the junction of the eighth and ninth costal cartilages. The flatness begins at the sixth rib in the nipple line. The surface is, as a rule, smooth, though toward the navel slight irregularities are felt. The edge is not very well defined. A little within the nipple line, at about five centimetres to the right of the navel, there is felt on deep palpation a little projection, rounded, somewhat nodular, and which appears to be attached to the liver border. It is not movable, and is in the position and extremely suggestive of the tip of the gall bladder projecting beneath the liver margin. The edge of the spleen was just palpable on deep inspiration. The splenic flatness began in the eighth interspace. The stomach was not dilated and the gastric juice contained free hydrochloric acid.

The urine was bile-stained, clear, acid, 1 025, contained a trace of albumin and a few hyaline and granular casts.

The patient remained in hospital three weeks. The jaundice varied considerably in intensity, and the complexion got at times very much clearer. The stools were clay-colored, and at no time were of such tint as to indicate that at any rate much bile passed into the intestine.

During his stay in the bospital the patient gained a couple of pounds in weight, his appetite was good, and he was always able to be up and about.

The nature of the trouble did not seem at all clear. The patient's habits, the length of time the liver had been enlarged, the size of the organ, without ascites, favored the view that he had a form of hypertrophic cirrhosis, to which even the intensity of the jaundice was not opposed. The question of syphilis was also discussed. The stools, however, had rather the character of a definitely obstructive jaundice, and at times he was intensely yellow. There seemed a possibility that the common duct was obstructed, and, though he had not the intermittent fever and chills so common in the impaction of a gallstone in this part, yet the jaundice was variable, and the nodular mass at the edge of the liver was suggestive, to say the least, of enlargement of the gall bladder. He wished for an operation to determine the nature of the trouble, and agreed to return for an exploratory laparotomy.

January 2, 1893.—Patient came back to-day in practically the same condition; but he has gained a couple of pounds in

weight. There is no change in the liver, and the nodular enlargement can still be felt. The skin is deeply jaundiced, the stools clay-colored, and the urine very dark.

6th.—This morning Dr. Halsted did an exploratory laparotomy. An incision was made about three inches below the costal margin, just above the border of the liver and following its curve. When the peritonaum was opened there appeared to view, covering the entire surface of the liver, a smooth structure, covered by peritonæum, looking like omental tissue, containing vessels and fatty tissue. It was adherent to, but could be moved like a skin upon the surface of the organ. The nature of it was doubtful. There were numerous adhesions between the edge of the liver and the transverse colon, which had to be separated, and the lower surface of the liver was united by adhesions to the adjacent parts. In the separation of the adhesions there was a good deal of bleeding, and the vessels had to be tied. The gall bladder was not found, and it was impossible under the circumstances to make a satisfactory dissection of the gastro-hepatic omentum. Nothing abnormal was felt about the head of the pancreas, and no stone could be felt in the duct. The edge of the liver itself was irregular, and at a little distance from the margin there was a distinct indentation or groove. The nodular mass which we felt so repeatedly was, in all probability, a projecting portion of this ledgelike edge. The membranous fold already mentioned was loosely adherent to the surface of the liver, and, when lifted up, there were numerous bleeding points which had to be touched with the Paquelin cautery. The surface was somewhat irregular, roughened, of an intensely bluish, almost plum color, and looked like an organ in a state of hypertrophic cirrhosis.

It did not seem possible to be able to determine precisely the nature of the remarkable fold of membrane covering the liver. It covered the left lobe and extended up as far as could be felt. It seemed more like a large properitoneal membrane covering the liver. It was outside of the liver capsule, which was not itself thickened.

I heard from this patient last on November 6, 1893. His jaundice had all disappeared, and the stools and urine are natural. He had improved a good deal, but the dropsy had been very much worse, and he had been tapped twelve times.

(c) Cancer of the Gall Bladder.—New growths of the gall bladder, which are not very uncommon, have of late attracted much attention, particularly in their relation to gallstones. The diagnosis is in some cases easy, in others extremely difficult, and if the patient has had attacks of gallstone colic, and presents a rounded tumor mass below the edge of the liver, the condition is very naturally regarded as simple dilatation of the gall bladder. The following cases, which have been under observation, illustrate certain points in the diagnosis:

Case XI.1.—Persistent Jaundice with Emaciation and Ascites; Nodular Tumor at Edge of Right Lobe.—Magdalen II., aged fifty-two years, admitted to Ward G on October 18, 1892, complaining of swelling of the abdomen and legs.

Her father died of tuberculosis. No history of cancerous disease in the family.

The patient has always been very healthy, was married at twenty-two; had one child. She has been troubled for many years with constipation. She has never had attacks of colic.

The present illness, dating from about the middle of June, began with vomiting, after which she became yellow and had itching of the skin. The jaundice has never entirely disappeared. The legs became swollen about the end of August, and the abdomen six weeks ago. There has been pain in the back,

so that she always has to lie on the side; otherwise she has not had much distress. The stools have been yellow. She has had but little vomiting. There has been progressive loss of weight, and she has beeome very weak.

Present Condition.—Patient is much emaciated, and has an intense olive green jaundice. There is general anasarca. The abdomen is extremely distended, and the lower zone of the thorax is expanded. Without going into details foreign to the main point, it may be said that she had all the signs of obstructive jaundice, and an ascites which required frequent tapping. The immediate interest of the case was in the condition of the liver. After tapping, the liver was distinctly palpable, and in the parasternal line the rounded edge could be felt about two fingerbreadths from the costal margin. Passing toward the flank, in the anterior axillary line, a prominent nodular mass was reached, and here the liver margin was nearly seven centimetres below the costal margin. The mass felt about the size of a walnut, was prominent, not umbilicated. No other masses could be felt, but the edge of the liver in the parasternal line was somewhat irregular.

Remarks.—This illustrates a group of cases of obstructive jaundice the precise cause of which is often difficult to determine. The persistent icterus and the loss of weight suggest a new growth, but whether in the stomach, the pancreas, or the liver itself is almost impossible to say. A test breakfast shows free hydrochloric acid, and she has not had much vomiting since admission to hospital. The stools are grayish yellow, not fatty and not suggestive of pancreatic disease. The nodular body at the right border is the main objective point in the local examination, and the question discussed between Dr. Thayer and myself before the class has been whether this is a secondary nodular growth or the projecting end of a firm, hard, cancerous gall bladder. To my touch it rather resembles the former, feeling as though the finger could be passed all around the liver tissue at its base. Supposing it to be secondary cancer of the liver, the organ is not nearly so large as is common in this condition in the space of five or six months. On the other hand, in primary cancer of the gall passages the liver is often not much enlarged, and the jaundice, as in this case, is intense from the outset. A point in favor of this view is the absence of evident signs of disease of the stomach, pancreas, or intestines.

Patient died November 16, 1892. The above comments were written before the patient's death. The autopsy showed a primary carcinoma of the gall bladder, the end of which was the nodular body which we had been able to feel so definitely on palpation. The walls of the organ were greatly thickened, and it contained nearly one hundred small gallstones. There was great induration and thickening about the common bile duct, the head of the pancreas, and in the gastro-hepatic omentum. The common duct passed through this indurated tissue and was almost occluded. The liver weighed only fifteen hundred grammes and presented numerous medium-sized cancerous nodules throughout its substance.

Case XLII. Cancer of the Gall Bladder; Jaundire; Progressive Emaciation.—E. S., aged fifty-four years, admitted to Ward G on January 25, 1893, complaining of pain in the abdomen and soreness in the back. There is nothing of any moment in the family history. She has been married; has had six children; four miscarriages. She has never had uterine trouble; no serious illness until the present attack.

More than a year ago she had pains in the back, sometimes quite severe, and accompanied with high-colored urine. After several of these attacks she had passed small calculi in the urine. She has had none of these attacks and has not passed a stone for about a year. She has been failing in health for the

past few months, has had indigestion, belching, and occasional attacks of vomiting, and has lost a good deal in weight. About five weeks ago she noticed change of color in the skin and that she was getting yellow, and for about the same time she has had a dull aching pain on the right side of the abdomen. The urine has been high-colored, and the stools, which formerly were very dark, were light-gray in color.

The patient is a medium-sized woman; face thin, but the body and limbs still well nourished. There is moderate jaundice.

Abdomen full; panniculus well retained. On palpation, it is soft, nowhere painful except at a point about five centimetres below the costal margin in the nipple line. Here there is a firm mass which extends to the left to within six centimetres of the umbilicus, and at this border the fingers can be placed directly beneath it. Below it reaches to the transverse nave line, and is here rounded, and the fingers can not be placed so well beneath it as to the left. To the right the margins are not very clearly defined, but it extends nearly to the tip of the tenth rib. Above, it can not be separated from the liver margin. It feels like a rounded mass, larger than a lemon, is extremely resistant, hard, and, though it has the situation of the gall bladder, it scarcely conveys the impression of the rounded, pear-shaped outline of that organ. The right kidney can not be felt. The liver dullness is not present in the midsternal line, just three centimetres and a half in the parasternal and five centimetres in the nipple line. The mass above described, though directly continuous with the liver, presents a flat tympany on percussion. Deep pressure from behind in the right flank presses the tumor mass forward.

The spleen is not enlarged, stomach not dilated, and the pelvis is clear. The urine is very dark in color, 1'016, pale; bile
pigments present; no sugar; a few granular casts. The stools
are clay-colored and very offensive. Repeated examinations
showed no essential change in the condition of the tumor mass.
The jaundice became very much more intense, though the general symptoms were somewhat ameliorated. She took her
food better, and had much less pain.

The case was regarded as tumor of the gall bladder associated with gallstones, and probably malignant disease. The patient's condition was so satisfactory that it was thought advisable to have an exploratory operation to determine if anything could be done.

February 8th.—This morning Dr. Halsted made an exploratory operation. The mass above described was in the situation already referred to—between the transverse colon and the under surface of the liver, to which it was firmly attached. The adhesions to the colon were so tight that it was not thought advisable to attempt to separate them. The tumor mass was firm solid, and grayish white in color, passed beneath the surface of the liver, and occupied the position of the gall bladder. The liver itself was not enlarged, but the edge could readily be felt about six centimetres above the lower border of the tumor mass.

The jaundice persisted; she got progressively emaciated; the wound healed. Her friends took her home on March 2d, where she subsequently died.

Carcinoma of the gall bladder is not very easy to recognize, but there are certain suggestive features in suspected cases. The disease is most common in women—two thirds of the cases collected by Musser. In seven eighths of the cases the cancer has been associated with gallstones, so that a history of colic or of previous jaundice should be sought for. Rapid emaciation, with or without jaundice,

and the development of a cachexia within three or four months, speak for cancer; simple hydrops vesicæ may persist for months without impairment of the general health. Chills and fever are, as a rule, against neoplasm. So long as the disease is confined to the gall bladder jaundice is not present, but when it extends to the common duct the icterus is intense and persistent. Ascites may be caused by the propagation of the disease to the peritonæum by pressure of secondary masses on the vena portæ, by extension to the gastro-hepatic omentum, as in Case XLI, and occasionally is due to thrombosis of the portal veins.

The local features are variable and uncertain. In the cases I have narrated the walls of the gall bladder were infiltrated, but the cancer may be at the outlet, causing obstruction with great dilatation and a tumor resembling in all respects that produced by any other occlusion of the cystic duct. When the fundus is involved the tumor is harder, more resistant, not so movable as in simple hydrops, and the growth may be very rapid. The liver is not usually much enlarged, even when secondary nodules are present. Aspiration of the tumor gives most important indications. A clear mucoid fluid favors gallstones; turbid, albuminous contents suggest neoplasm, as does also blood or a blood-stained fluid. Fragments of the new growth may be found in the material aspirated. Pure bile is rather in favor of gallstones, and indicates that the cystic duct is not involved.

But taking all the circumstances, general and local, into consideration, you may not be able to reach a conclusion, in which case remember that the hazard of an exploratory operation is slight, and that by far the most frequent cause of tumor in the region of the gall bladder is cholelithiasis.

# Original Communications.

# ON TUBERCULAR AND SUPPURATIVE PERITONITIS.\*

BY CARL BECK, M.D., NEW YORK.

It is only within a few years that surgery has become a rival of internal medicine in the field of the different forms of peritonitis—just as the kidney was regarded to be the domain of internal medicine only until Gustav Simon, by performing the first successful nephrectomy, showed this to be an error—while before treatment of the different forms of peritonitis seemed forever to be condemned to consist of opium or calomel and the ice bag or the flaxseed poultice.

It is a characteristic sign of our period that now the physician and the surgeon are in entire accord in these cases, and are mutually dependent one on the other.

The first step in that direction was undertaken when in this country the indications for and the limits of the

\* Read in part before the Surgical Section of the Academy of Medicine, November 13, 1893. Conclusions read in absentia before the Eleventh International Medical Congress, Rome, March 30, 1894.

operation for appendicitis were outlined. The gratifying results which are obtained in this affection have shown that this direction was the right one.

But not alone this—they encouraged surgeons to approach the surgical treatment of peritonitis, heretofore a noli me tangere for the scalpel.

We are not, however, so far advanced as the statistics of Stühlen show,\* where in seventy-eight cases of suppurative peritonitis fifty recoveries are reported.

These apparently splendid results have to be taken cum grano salis. There can be no doubt that the author knows of fifty successful cases, but he did not know of many hundreds of fatal cases besides the twenty-eight which he published. It is quite natural that brilliant cases are made known, while the fatal ones, with few exceptions, are passed over; therefore only such statistics can be valued scientifically where all the cases of their kind are reported together. So far as my knowledge goes, these postulates in reference to suppurative general peritonitis have been fulfilled only by Miculicz,† Krönlein, † and Körte.\*\*

These reports are much less favorable, but if the fact is considered that a cure obtained in even one desperate case, which was formerly thought to be impossible, it is a victory; they certainly present a new phase in the history of surgery.

Statistics, of course, will appear in a different light if the cases are selected, or if such cases are only operated which seem to give a better prognosis than others. But what we demand is that a series of operations inclusive of those without any prospects should be reported as well.

Experience has shown that recovery has taken place even when the surgeon proceeded to the operation without the slightest hope, and where the pulse has not been perceptible, and, vice versa, cases ended fatally where the prospects were comparatively good.

As a patient suffering from general suppurative peritonitis has, indeed, nothing to lose, he should be operated upon at all hazards. The permission of the patient can be obtained almost always on account of his great suffering and his cognizance of the unfavorable outcome.

The trouble in getting the permission comes—at least this is my experience—in such cases, from the objection of the attending physicians, and not from the patient or his friends. Consultation and consideration usually consume most valuable time.

Laparotomy always enables us to evacuate the pus from the many pockets and crevices of the abdominal cavity, and to destroy adhesions, which follow the inflammatory process and are generally a great impediment to the thorough evacuation of the pus. But even in the most complicated or extensive cases we would only leave a trifle, thereby at least reducing the quantity of the dangerous germs consid-

<sup>\*</sup> Stühlen. Drainage des Peritonäum bei Peritonitis. Strassburger Kbnik. 1890.

<sup>†</sup> Miculicz, one recovery among fourteen cases. (Paper read at the Eighth Congress of the German Surgical Society at Berlin.)

<sup>‡</sup> Krönlein, two recoveries among seven cases.

<sup>\*</sup> Körte, Chirurgische Mitcheilungen von Bruns, 1890, Bd. vi. W. Körte, Archiv für klinische Chirurgie, Heft 3, Jahrgang 1892.

erably. Furthermore, the intra-abdominal pressure will be necessarily lessened to a great extent, so that respiration may become free at once, and, again, a perforated organ eventually may be occluded or necrotic tissue (gangrenous appendix, for instance) may be removed.

A thorough disinfection of the abdominal cavity is still a desideratum, but much can be done by extensive drainage with rubber drainage tubes surrounded by iodoform gauze. Strong antiseptics are not borne by the peritonæum on account of its great tendency toward absorption and of its irritability. Weak antiseptic or sterilized solutions are useless in such cases. But even if strong antiseptics, like bichloride, for instance, could be borne, neither the stream of irrigation nor wiping off with sponges could on account of the anatomical condition of the abdomen reach every corner of the cavity. Especially in hernias, where gangrene is suspected, I have employed bichloride of mercury repeatedly, to the terror of many colleagues, but with apparent success, and have never perceived any symptoms, that could be traced to its use.

I employed without fear a 1-to-2,000 solution for disinfecting the intestine, taking the precaution, of course, to occlude the abdominal cavity with sterilized compresses so as to irrigate only the part of the intestine lying outside the abdominal cavity, and to wash immediately after with sterilized water.\*

Induced by the great ease with which iodoform powder as well as iodoform mixtures were borne by patients suffering from tubercular peritonitis, I thought of using this ideal drug in general peritonitis also: During the past nine months I have done so by infusing one ounce of a tenper-cent. mixture of iodoform and glycerin in five cases of general peritonitis and in two other cases where septic pus had escaped into the abdominal cavity during operation.

Though not claiming any specific results for this treatment, which certainly would be useless in acute septic peritonitis, it is remarkable that in five cases in which the chances of recovery on account of their nature were very poor, all with the exception of one, which was operated on at a very late stage, terminated favorably.

It is conceivable that the virulence of the pus may be weakened by the coabsorption of the iodoform. I do not refer to a localized accumulation of pus—that is, to a cavity, no matter how large it may be, which by adhesions is well separated from the cavum abdominis. Such extraperitoneal and extremely favorable cases should not be called or treated the same way. I would suggest the same name as for other similar abscesses, characterized by their seclusion—that is, empyemu.

The most frequent abdominal abscess of this kind is the one depending upon appendicitis.

The best chances for the operation naturally offer at the earliest stage of suppurative and in tubercular peritonitis. It is often difficult to make an exact diagnosis before laparotomy is done. I can safely say that in the greater number of cases of extensive appendicitis in which I have been called by the attending physician, it was to operate for "internal obstruction." Any kind of peritonitis, on account of sudden paralysis of the intestines, can produce the symptoms of obstruction—namely, stercoraceous vomiting and retention of faces and flatus.

On the other hand, peritonitis, caused by perforation, may follow obstruction, so that a definite discrimination is very difficult, if not impossible. The character of the pulse, as some maintain, should show if perforation had occurred already or not. I do not think this to be reliable, as to my surprise I once found a good pulse although, as laparotomy later on showed us, perforation had taken place quite a time previous.

The exploratory needle may be used in doubtful cases, but it very often fails to yield pus, which then is no proof that there is none. If by microscopical or bacteriological examination we could demonstrate the coccus characterizing the infection at the time of the operation, we could be more positive still.

I have repeatedly been able to affirm that, when the axillary and rectal temperature differed for more than two degrees, pus in the peritoneal cavity was always present. In one case of a young married woman, who died from general peritonitis following appendicitis, I found the temperature to be 99° in the axilla and 103.5° in the rectum. Here, as the symptoms of appendicitis were only very slight for the first four days, a prominent surgeon had advised expectant treatment. Suddenly perforation took place, the patient collapsed, and then an operation was declined.

If the intestines are very much distended, the exploratory needle might be fatal, as the hole in the paralyzed intestine may remain open. All these facts show that laparotomy in all doubtful cases is the lesser risk.

In the cases of tubercular peritonitis I do not hesitate to confess that I have never been able to make the diagnosis before the laparotomy.

As I understand it, the diagnosis of a tubercular process can only be made by seeing the tubercular nodules or by demonstrating the bacillus of Koch under the microscope. The latter proof can easily be furnished in the sputa of a consumptive, but in tubercular urine, in tuberculosis of joints, glands, or of the peritonæum, it is only exceptionally that such evidence can be secured, and then only if serous or purulent fluid in the abdominal cavity is present, which usually is found only at an advanced stage.

Our aspiratory technique is not so far developed as to entice the bacilli into an exploratory needle; and, if the symptoms are developed beyond any doubt, then local treatment offers hardly any chance.

The cures which I have effected after having performed laparotomy have now, a year and a half after the operation, remained perfect. How this was achieved I fail to understand, but nevertheless it is a fact. If this is only due to the exposure of the abdominal organs to the atmosphere, as is probable, it seems to me that the repeated infusion of an iodoform mixture is a great help and will make the cure more permanent.

The idea of inflating air was quite obvious regarding

This should be called "typhlo-empyema."

The best chances for the operation naturally offer at

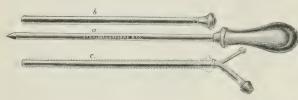

<sup>\*</sup> Compare Resection of the Intestine in Gangrenous Hernia, by Carl Beck. Medical Record, April 8, 1893.

the theory of the influence of the atmosphere, but the difficulty of diagnosis will always be the weak point for its indication. The iodoform infusion on the other hand will be useful in doubtful cases, be it for exudatory processes demanding absorption or for its specific antitubercular effect.

I generally infused one ounce of a ten-per-cent. mixture of iodoform and glycerin.

Iodoform. subt. pulveris	50	parts.
Mucil. gummi arab	23	6.6
Glycerin	83	6.6
Aq. destilq. s. ad		66

This was done in intervals of one week, altogether between three and eight times. No after-effect ever followed. Generally I used my own irrigation trocar, which I have devised for the treatment especially of tubercular

after the stilette has been withdrawn. This second can- pear that he can not stand any such manipulations, which nula presents a double-barreled tube. Through the small tube, which can be brought into connection with an irrigator, a sterilized liquid can be infused. Through the large tube, solid particles, which generally have to be expected in the pus, can be washed out. Afterward, through the large tube, iodoform and glycerin or oil can be infused either by an irrigator or by a piston syringe. The advantage I claim for this instrument is that the force of the irrigation will cause solid fragments to dislodge and take them away with the recurrent flow. At the same time the force of the water can easily regulated.

Patients who had had opium administered before the operation seemed to stand the laparotomy better, as the peristalsis was suppressed, thereby favoring adhesions.

As in all other inflammatory processes every surgeon is looking for immobilization as a conditio sine qua non, and he should look out for this "splint principle" in the abdomen also. Patients who have had calomel given to them are generally much weaker and seem to have poorer chances for recovery. They especially require stimulants before the operation (camphor, or preferably injections of hot wine or cognac into the rectum). If the patient's condition will allow it, the stomach should be washed out before the operation.

Ether anæsthesia was only induced superficially and only at the beginning, as the pulse was generally very weak.

It is less cruel to bother the patient and save his life than to give him the so-called benefit of a full anæsthesia and kill him under the pretext of humanity. If necessary, the operation should be done under a simple cocaine anæs-

In such cases where marked swelling at the right iliac fossa was present I incised there. The best view I generally have had by making a vertical incision at least four inches in length in a line uniting the anterior axillary line with the spina anterior superior ossis ilii. Whenever this was not satisfactory, I added a cross incision (T-shaped) toward the lumbar region, rectangular to the longitudinal one. Otherwise I prefer to open the abdomen through the linea alba.

Here a large, bloodless, and quick incision can be made. Then with hot sterilized water the pus is evacuated.

Wherever small cavities were formed, from adhesions, drainage-tubes, surrounded by iodoform gauze, were introduced-once seven in number, all discharging through the abdominal opening.

Fibrinous exudations were always wiped off with steril-The difference of its construction from other trocars ized gauze, except when they extended over too large a consists of the fact that we can introduce another cannula portion of the intestine so that bleeding was excessive or

too much time wasted. When the seat of a perforation is found it should be pulled outside, and by separating it from the abdominal cavity by sterilized compresses, it should be irrigated with a 1-to-2,000 bichloride solution and then washed with sterilized water. After this, if the condition of the patient allows it, the perforation (or opening) should be closed. If not--that is, if it should ap-

may require fifteen to twenty minutes' time-that portion of the viscera should remain outside enveloped in iodoform gauze until the patient's condition allows closure and replacement.

In the larger proportion of cases the vermiform appendix causes perforation. Following common surgical principles, it is, of course, advisable to remove the appendix. But if this can only be done at the expense of destroying adhesions, which sometimes may save the patient's life, or, if long searching is necessary, it is better to pack iodoform gauze around this portion, hoping for a later removal or separation.

Iodoform gauze adapts itself tightly to the serosa, and becomes loosened only when suppuration becomes copious. Sometimes I kept it in the abdomen for two weeks. It then (ten per cent.) still contained plenty of iodoform, and cultures showed it to be still sterile.

If there are symptoms of retention afterward, the finger must be introduced, not the probe. Hereby valuable information can be obtained, as Case III shows, where I am quite sure that it was only through extensive counteropening and drainage that I saved the patient's life.

So far, however, as the removal of the appendix is concerned, I do not remove it simply because it may be attached to the tube or ovary by previous inflammatory processes, in case it is of normal appearance.

In one case where I performed oophorectomy, I found a very long and wide appendix of normal appearance. Touching it accidentally, I felt some hard substances in its distal end, which I could easily press out into the cæcum. Assuming that there was enough room as well as contractile elements to let fæcal matter circulate in the appendix, I did not remove it. The patient did not show any symptoms in this direction later on. I have repeatedly felt the appendix in women, but never in a male patient, in whom I often have tried to find it, through the rectum.

But a distinct impression of its condition we are probably never able to get by palpation. In this particular case, if I had tried to palpate the appendix I should, on account of its contents, probably have assumed a pathological condition of its structure.

And, vice versa, as one case below shows, even its exposure after laparotomy sometimes may leave a doubt, if there is such a change as would justify its removal.

#### HISTORIES.

Tuberculosis.—Case I.—Gerdic K. (case presented to the surgical section of the Academy of Medicine, December, 1892, and December, 1893), who at the present writing is fifteen years old, came under my observation in October, 1892.

Since about October, 1891, she had had pain and tenderness in the hypogastric region. Physicians whom she had consulted diagnosticated dyspepsia, chlorosis, endocarditis rheumatica, etc.

In May, 1892, after having swallowed some seeds of a lemon, she claims that the pain suddenly assumed an acute character.

Soon afterward the pains became permanent and localized in the right iliac fossa.

Dr. George W. Rachel, who had her at this time under his charge, reported to me that she had suffered from appendicitis.

Two weeks after the onset of the pains in the right iliac region she was free from fever and was able to go about, but held the body in a slightly bent position. The pain remained the same as before.

Dr. A. H. Stiebeling, who saw her then, discovered a hard, well-defined tumor of the size of a man's fist apparently attached to the os ilii, on account of which he advised surgical interference.

I did not consider a laparotomy justifiable at this time, as I was in doubt about the character of the swelling, which I thought might be the residual product of a perityphlitic process, and which eventually might undergo absorption.

I therefore put the patient in bed and kept her under observation. Hot and cold applications were made, electricity and massage were tried, but all without avail.

Opium gave but temporary relief.

Aspiration of the swelling yielded blood.

After having injected a saturated solution of iodoformether into the tumor four times at intervals of five days, the swelling subsided almost entirely. But the pain remained the same as before, so that the patient herself urged me to an operation.

When I performed an exploratory laparotomy, November 3, 1892, I found about three tablespoonfuls of a light serous fluid in the abdominal cavity. The appendix appeared to be normal, and was attached to the right ovary and to the mesocolon.

The extensive adhesions were divided at once.

At the same time a condition was found which previously had been unsuspected—that is, the peritoneum and mesentery were covered with *innumerable* tubercular nodules, varying in size from a pin's head to a pea.

The intestines were apparently untrammeled.

Following the principle which I have adopted in the treatment of tubercular glands and joints, I rubbed the affected portions with iodoform, using about five grammes of the powder.

There was no trouble after the operation, except that, on the fifth day following, an eczema appeared (probably due to iodoform), extending over the entire abdominal wall. The patient could not resist the temptation to scratch, so that the skin sutures partially sloughed. On account of this, union was not perfect till three weeks after.

On the fourteenth, twentieth, and twenty-seventh days after the operation, an ounce of a ten-per-cent mixture of iodoform-glycerin was injected into the cavum peritonei without causing any trouble.

The pain in the right iliac region disappeared at once, so that I feel quite confident in saying that it was due to the adhesions.

At the present time, nearly a year and a half after the operation, she is perfectly well.

During the winter cod-liver oil was given, while in summer guaiacol was substituted.

Case II.—Mrs. G., twenty-four years of age, married since November, 1892, gives a history of personal tuberculosis.

She had always been well until two weeks after her wedding, when she took sick with chills and sharp pains in the sacral regions. Every afternoon for five weeks following her temperature reached 104.5°.

Dr. Volkenberg, who has been her family physician, diagnosticated peritonitis.

When, on January 11th, I first saw the patient in consultation, I found a temperature of 104.5°, a weak pulse of 140, and a respiration of 31. The abdomen was distended, and immediately above the symphysis pubis quite sensitive to pressure.

Tympanites was but slight.

The legs were drawn up and the thighs flexed upon the abdomen.

Constipation had been present during the first week. There was also disturbance in urinating. Menstruation had been absent for two months.

By a vaginal examination under ether we found the left ovary enlarged to the size of a hen's egg.

The uterus was drawn toward the left side, fluctuation was well developed in the posterior *cul-de-sac*, and the neighboring tissues were indurated.

As there was a history of gonorrhea, I was quite positive in diagnosticating an ovarian abscess.

A prominent gynæcologist of this city, who kindly examined the patient under anæsthesia with me, concurred in this opinion. Laparotomy on the following day revealed the presence of about a pint of sero-fibrinous fluid in the abdominal cavity and of innumerable miliary tubercles,

which studded the peritonaum, mesentery, and intestines.

The left ovary was enlarged, but no evidence of suppuration was found in it or in the tube.

About six grammes of iodoform powder were dusted over the tubercular field, and the abdomen was then closed. Uninterrupted recovery followed.

The temperature remained normal, with the exception of on the tenth day, when it went up to 104° F.

An explanation for this phenomenon could not be found.

On the thirteenth, twentieth, and twenty-seventh days after the operation, an ounce of a ten-per-cent mixture of iodoform glycerin was injected into the peritoneal cavity.

Three weeks after the operation the patient was discharged from St. Mark's Hospital, and until to-day has remained well. A slight cough, which was present before the operation, has, curiously enough, disappeared.

Case III.—Anna R., aged fifteen years, with good family history, had measles, scarlet fever, and diphtheria several years ago. For two months she complained about a dull sensation around the umbilicus, and at the same time her abdomen became distended. The appetite was poor and in the evening an exacerbation of temperature.

On May 4, 1893, on physical examination, I found a thin, slimly-built patient, having a temperature of 102.5°, a pulse of 140, respiration of 23. Ascites was present, so that an exploratory puncture was made. A microscopical examination of the fluid which was drawn shed no light on the nature of the disease. The microscopist suggested cirrhosis of the liver. An exploratory laparotomy revealed the presence of tubercular nodules, the greater number being of the size of a pin's head and extending over the peritonæum, intestines, and mesentery. The other abdominal organs appeared to be free.

Two quarts of a light serous fluid was discharged. About six grammes of iodoform powder were dusted over the tubercular area. The abdominal walls were united with the exception of a space to allow the introduction of a rubber drainage-tube, surrounded by iodoform gauze, which was removed two weeks later, when the serous discharge, which during the first few days was quite copious, stopped entirely.

Recovery has remained perfect.

General Peritonitis. Case I.—Jacob W., aged seven years, who had always been in good health, was taken sick suddenly with chills and sharp pains in the region of the umbilicus. Vomiting set in a few hours later.

Dr. Sandberg was called, and, as laxatives and enemata were of no avail, he was suspicious of ileus, and advised laparotomy at once.

When I saw the case in consultation (May 17, 1893) I found the following state present:

The patient, well nourished, showed the typical facies Hippocratica. The pulse was 131 and weak, temperature 101°, and respiration 32.

The abdomen was tympanitic and very painful to the touch. Resistance or particular tenderness at the right iliac fossa was not present.

After having washed the stomach and the bowel opium was administered, but only slight improvement followed, so that on the following morning I made a large incision at the usual point. About three-tablespoonfuls of gray pus, which had an offensive odor, was discharged. When I pulled the intestines out they were seen to be of a dark-red color and loops were attached to each other by fibrinous exudations. I opened a second pus cavity above the right synchondrosis sacro-iliaea. Looking for the vermiform process, I found the cæcum tightly adherent to the right sacro-iliae synchondrosis, from which I was afraid to loosen it.

A cross incision reaching nearly as far as the umbilicus was added, to give a better view. About two yards of intestine, covered with fibrin and purulent exudations, could now be brought into view. With hot sterilized water the abdomen was irrigated and the exudations dissolved off with peroxide of hydrogen.

Being fearful for the fate of the appendix in the depth of the iliac fossa and of the dark-red cæcum, I united the edges of the cross incision only after having dusted iodoform powder over those portions of the intestine which had been covered with exudations.

One loop of about twelve inches in length I kept outside the abdominal cavity by enveloping it in iodoform gauze, thereby being able to pack some gauze around the excum down in the fossa. Into the other corner I introduced a few iodoform wicks.

The patient's condition was satisfactory after this, until five days later an elevation of temperature induced me to examine the cavity by introducing my index finger, whereon I discovered a retention of pus in the lumbar region. I therefore made a counter-incision above the crista ilii, introducing a large drainage-tube surrounded by iodoform gauze. Great improvement followed.

Ten days after the operation I replaced the enveloped intestine and at the same time tried in vain to find the appendix.

As the patient made rapid and satisfactory improvement I refrained from further attempts to remove the appendix.

But three weeks after the first operation the patient complained of sharp pains around the bladder; frequent micturition troubled him, and his general condition became impaired. No retention of pus could be detected by introducing a grooved director all around.

Examination through the rectum as well as of the urine revealed nothing particular.

The patient became gradually weaker, had several attacks of syncope each day, and had incontinence of fæces, so that we were fearful lest all our previous proceedings were useless.

After much opposition on the part of the parents of the unfortunate child, I succeeded in pushing my finger toward the bladder and evacuating about two tablespoonfuls of creamy pus, which settled in a cavity extending from the posterior wall of the bladder to the rectum. Forcing my index finger as far as possible toward the opposite side, I incised on its tip so as to enable me to pull through a drainage-tube nearly a foot in length.

Great improvement followed.

Two weeks later I drained this "post-vesical" cavity from the right side only, so that the counter-opening on the left side became obliterated. The patient was allowed to get up contrary to my instructions, and was taken sick again with chills and convulsions.

When I was called I was able to discover retention of pus in the same dependent cavity.

Drainage was again made on the left side, as before, this time having the rubber drain off at the right side first. Two weeks later the canal was packed with iodoform wicks for one week, whereafter recovery became perfect.

The patient now is as strong and healthy as he ever

In the right iliac region a very large ventral hernia, undoubtedly due to the weakening of the abdominal walls caused by the long-continued drainage, is present.

Although this does not disturb him, I have suggested an operation, which, under the present circumstances, could not be dangerous.

Here, then, is another case which shows that after a successful laparotomy of this kind a good many dangers may arise from the retention of pus. These dangers can readily be counteracted by prompt and energetic interference.

Great stress must be laid on the introduction of the finger as a diagnostic aid which can never be supplied by a probe.

Case II.—Abraham T., of Brooklyn, aged forty-three years, had always been well until four days ago, when he took sick with chills, nausea, and sharp pains in the right lilac region. Castor oil was administered, but without results.

When I was called in consultation with Dr. Sachs (June 12, 1893) I found the abdomen moderately distended and tender. The pulse was 104 and weak; temperature,  $102^{\circ}$ , and respiration, 26.

After I had made a T-shaped incision at the usual place, a dark serous fluid discharged.

The intestines, as well as the mesentery, were of a darkred color.

After having pulled out a loop of the bowels the index finger involuntarily opened an abscess cavity. About four tablespoonfuls of offensive pus were discharged.

As the patient's pulse became so feeble that it could not be felt, the ether was left off and the operation finished without an anæsthetic.

In the depths of the cavity the gangrenous appendix was found and secured by a forceps.

When ligated, it broke off.

All attempts to close the opening by sutures were useless on account of the brittle condition of the tissues.

While this portion of the intestine was temporarily left outside of the cavity enveloped in sterilized gauze the other portion of the intestines was inspected. Fibrinous exudations covered them to the extent of about a yard, so that they were all pulled outside.

The abdominal cavity was then secluded by packing always been well until shortly after numerous sterilized compresses around the opening and a showed the symptoms of pyosalpinx.

bichloride solution (1 to 2,000) irrigated for about ten seconds. It was then washed with hot sterilized water for about two minutes, thereby trying to remove fibrinous exudations. A ten-per-cent. mixture of iodoform glycerin was infused after the intestine was replaced. Only three sutures were used to occlude the cross incision, but the long incision was left wide open so as to allow the packing of iodoform gauze around the brittle portion of the caccum.

Perfect recovery followed.

The gauze was entirely removed on the tenth day.

Case III.—Valentine R., a strong man of thirty-seven years, with a good family record, was always well until December 27, 1893, when he was suddenly taken sick with intense abdominal pains. On the following day frequent vomiting set in, and the abdomen became distended. Laxatives, enemata, and injections with the Seltzer-water siphon were administered without producing a movement of the bowels. With the trial of other useless therapeutics two days were wasted, so that on December 30th, when I first saw the patient, the chances seemed almost hopeless.

The scarcely perceptible pulse was 160, the temperature 99.5°, and the respiration 34.

In the right iliac region well-defined dullness could be demonstrated, indicating a large purulent exudation which was found after incision.

An aspiratory puncture yielded yellow pus.

After caffeine per os and hot wine per rectum were administered, a large incision under an ether spray was made at the usual place.

About three quarts of pus, having a feculent odor, was discharged.

The gangrenous vermiform process, which was adherent laterally to the cacum, was removed without any difficulty,

To the original incision a second one, extending toward the umbilicus, was added.

Now three more cavities, formed by adhesions between the intestines, could be detected and were emptied.

Sterilized water was used only for cleaning the abdominal cavity. Wherever fibrinous exudations had been present, they were wiped off with sponges dipped into peroxide of hydrogen.

That portion to which the appendix had been attached was rubbed with iodoform powder.

Then one ounce of iodoform glyce†in was infused into the abdomen, the cavities as well as the smaller edges were drained with iodoform wicks, and the pocket adjoining the cæcum was packed with iodoform gauze. The original incision was kept open while the cross incision was united firmly.

The patient was stimulated after the operation, which fortunately had lasted only twenty-two minutes, and after four hours the pulse became distinctly perceptible. Slow but uninterrupted recovery followed.

The last tampons were removed eighteen days after the operation. No evidences of ventral hernia have as yet appeared.

Case IV.—Mrs. Rosa F., twenty-six years of age, had always been well until shortly after being married she showed the symptoms of pyosalpinx. A prominent gynacologist performed laparotomy successfully in the summer of 1891.

Union had taken place two months after the operation by second intention. For several months the patient had been doing well.

Then she became more and more constipated and her stomach was repeatedly so much distended that respiration was impaired.

On August 17, 1893, after having been constipated for five days, intense abdominal pains and repeated vomiting set in. The patient herself diagnosticated coprostasis and tried her own therapy, consisting of castor oil and hot poultices for twenty-four hours. On August 19th Dr. Talmey found the symptoms of ileus, which he pronounced to be due to constringent bands, the consequence of the inflammatory process following the removal of the ovary. As irrigations of stomach and rectum were of no avail, laparotomy was performed August 20th at the Post graduate Hospital.

The emaciated and weak patient had a comparatively good pulse of 120, a temperature of 103°, and a respiration of 24. Tympanites was present. Vomiting was almost constant.

A long incision in the linea alba exposed the incarcerated portion at once. After having loosened a few thin adhesions, about a quart of a green sero-fibrinous fluid was discharged.

Above the right synchondrosis sacro-iliaca a bundle of intestinal loops, belonging to the small gut, was discovered.

They were tightly attached to each other by fibrous adhesions and appeared like an M, so that the intestine was obstructed in four portions.

On its left side the intestine was attached to the stump of the left tube, where the oophorectomy had been performed previously. On its right side it was adherent to the vermiform process, which, being of unusual length (five inches), was of normal appearance; I then loosened it from its adhesions, which was possible only after resection of a considerable portion of mesentery adhering to it.

When the bands between the intestines were loosened three perforations appeared. A fourth occurred when I tried perhaps too forcibly to separate the attachments.

Fæcal matter was present in the pelvis, which was quite small. The perforations, after having been cleaned with bichloride sponges, were trimmed and adjusted. Czerny's sutures with thin iodoform silk were applied, and the serosa was rubbed with iodoform powder and covered with small strips of iodoform gauze.

One ounce of iodoform glycerin was then infused.

Through the abdominal wall, which was united so far as to allow the introduction of my hand, iodoform gauze was freely applied.

Uninterrupted recovery without elevation of temperature followed.

The gauze was removed partially on the third, and entirely on the eleventh day.

This is another case showing the great danger of the formation of adhesions after laparotomy. Only six months before this I had a similar (fatal) case (Dr. Dorfmann) where two years after oophorectomy in a patient twenty-two years

old constriction of the intestine, under exactly the same circumstances, had resulted. Perforation had not, however, occurred. (Iodoform was not used in this case.)

I know of about half a dozen similar cases, and therefore lay great stress upon the necessity of massage treatment after laparotomy, especially if inflammatory or even suppurative processes have followed.

A very cheap and practical way to carry this out and induce peristalsis is the frequent use of a cannon ball, to be rolled around the abdomen every morning for five to ten minutes.

Case V.—Fred D., aged six years (tubercular family history), had scarlet fever four years ago; was always well until, on November 9th, he suddenly took sick with sharp pains around the sixth and seventh ribs at the right anterior axillary line. Vomiting was present. Obstruction was successfully removed by the administration of calomel.

The attending physician was in doubt about the character of the disease, until six days after its onset the pain became permanent at the right iliac region, associated with well marked dullness. Tympanites became more developed and the patient showed signs of collapse.

When I saw the patient for the first time the pulse could hardly be felt, and was so rapid that counting was impossible. The temperature was 99° in the mouth and 102° in the rectum. The respiration was 30. Vomiting during the last twenty-four hours had been noticed but five times. An incision at the usual site was made without delay.

A similar condition was found as in Case III, except that no single cavities were noticed besides the large one around the appendix.

Ether had been given for a few minutes when cyanosis appeared, so that I finished the operation, as in Case III, without giving more anæsthetic. The patient bore this without any sign of excitement. Great improvement followed.

An hour after the operation the pulse was weak and frequent, but could easily be perceived. Vomiting stopped entirely, but on the following day he succumbed in collapse.

Case VI.—Miss Carrie R., aged twenty-six years, suffering from pyosalpinx (gonorrhæa), was operated at the Postgraduate Hospital September 24, 1893.

In loosening the adhesions from the tumor, which was of the size of a new-born child's head, it happened in spite of all the precautions taken before that the sac burst and a considerable amount of yellow, badly smelling pus escaped into the peritoneal cavity. Cultures afterward showed streptococci.

A piece of the mesentery as large as an adult's hand was so tightly attached to the sac that I had to remove it with the sac after having ligated it with iodoform silk. The appendix, normal in appearance, was adherent too, but could be separated without any difficulty.

An ounce of iodoform glycerin was infused and the stump then surrounded by iodoform gauze, which was removed four days after. The temperature was normal on the following day and recovery was perfect three weeks afterward. Since this article was written I have operated in two other cases of general peritonitis. In one case, that of a child, where the peritonitis was due to trauma, considerable improvement followed the operation. The patient died on the third day.

In the other case perfect recovery was obtained.

Mrs. W., twenty-nine years of age, mother of two healthy children, was taken sick with high fever, frequent vomiting, and pain in the right iliac region. Soon after the whole abdomen swelled. When I saw her in consultation with Dr. M. P. Jacobi at St. Mark's Hospital, I found the abdomen so much distended that localization was impossible. The pulse was 140 and weak, the temperature 101°, and the respiration 48. After having opened the abdominal cavity, general peritonitis was found. Fibrinous exudations were discovered to a great extent, and especially in the vicinity of the appendix. They were all wiped off. As the appendix itself only looked hyperæmic, I was in doubt if it was the source of the peritonitis, but, as I found no other, I removed it. It was only then, on splitting it open, that two gangrenous portions could be detected.

The respiration went down to 30 immediately after the operation, and the gauze was removed on the ninth day without any difficulty.

### A PORTABLE PERIMETER.

BY CHARLES L. DANA, M. D.

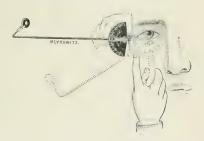

So far as I know, there is no perimeter which is easily portable, or which can therefore be used on patients who are ill in bed. Schweigger's instrument is altogether too large and heavy, and is not convenient for bedside use. I have devised an instrument which seems to supply fairly well the need for a portable perimeter. It can be easily and quickly used, and its records, while not perfectly exact, are sufficiently so for ordinary clinical use.

The instrument consists of a handle, slightly curved, to the end of which is attached at right angles a semicircular disk, on which degrees are marked. In the center of the disk is a movable rod six inches long, at the end of which is a clip in which test cards of different colors are placed. At the end of the handle, just beneath the attachment of the rod, is a slightly elevated square surface. The eve not tested being covered, the rod is fixed at the zero mark on the disk and the instrument held so that the elevated knob referred to rests on the lower edge of the orbit. The patient looks directly at the examiner, who places himself so that the patient's line of vision falls along the rod, the disk, and the examiner's eye. The rod is then moved laterally until the test card passes out of the field of vision. The figure is noted and the test repeated, bringing the card from without the field of vision inward. (See the cut.)

The horizontal field is thus obtained. By placing the instrument on the outer margin of the orbit, the vertical field can be measured; and an oblique measurement can also be got if necessary. The rod can be removed and thrust in a hole in the handle; the cards are carried in a

small clip, and the whole instrument can be easily carried in the pocket.

The instrument and its method of use are very simple, but not easy to describe. Its only defect is that it registers a few degrees too high unless care is taken.

Of course it does not take the place of the standard perimeters, but I have found it of great practical service in routine office examinations and in hospital and consulting work. The importance of carefully studying the visual and color fields in hysterical and neurasthenic states and in organic brain disease is now acknowledged to be very great. Hence, I hope that this instrument may prove of value.

It is made for me by Mr. E. B. Meyrowitz, of this city, who assures me that its price will be greatly less than that of ordinary perimeters.

#### A CASE OF

#### SUCCESSFUL SÄNGER CÆSAREAN OPERATION.\*

By THOMAS A. DUNDAS, M. D., ELMIRA, N. Y.

Gentlemen: I have the honor to report to you to-day the following successful case of the Sänger Cæsarean operation, both as to mother and babe. So far as I am able to discover, the mother is the smallest woman in stature ever delivered of a living child in this way:

Mrs. A. M. P., Elmira, N. Y., a hunchback dwarf, thirty-eight inches and a half tall, aged twenty-five years, primipara, weight a little over sixty pounds, deformed in her hands and feet, or what is commonly called double-jointed.

The conjugate pelvic diameter is an inch and a half, the vagina small and guarded by a very tough lymen, its opening admitting two fingers when forcibly distended, causing much pain. The abduction of the thighs is of an exceedingly limited degree—in fact, much like an ankylosed joint. She walks about the house with a peculiar rolling, waddling gait; on the street she either propels or is pushed on a tricycle.

I was consulted at the seventh month of pregnancy, and after a careful examination decided that in her case delivery by the natural channel would be an impossibility even after craniotomy.

Dr. Frank W. Ross afterward saw the woman with me, and confirmed the opinion already formed, that a Cæsarean section would give her the only chance of life.

The operation, with all its attendant dangers, I explained to

<sup>\*</sup> From a paper read before the Medical Society of the County of Chemung, N. Y., February 20, 1894, on Craniotomy, Symphysiotomy, and Casarean Section.

herself and husband. She asked if I had ever seen it, and I frankly said no, but thought I could perform it and save both herself and child. She gave her consent, and never afterward wavered for an instant, and expressed the most implicit confidence that I would pull her through. In this respect she was a model patient.

Her time being up, after trivial pains of two days' duration, with moderate dilatation of the os uteri, the operation was performed by me December 21, 1893. Valuable aid was given by Dr. Frank W. Ross, Dr. W. C. Wey, Dr. Jonas Jacobs, and Dr. C. W. M. Brown.

The bowels were thoroughly evacuated, urine was drawn, the body was bathed, and an aseptic vaginal douche was given. Abdomen was scrubbed, then treated with a Dichloride wash (1 to 1,000), then sponged with ether. The hands of the operator and assistants were scrubbed, then placed in a solution of permanganate of potassium, followed with a solution of oxalic acid, then rinsed in a bichloride solution. The instruments were all sterilized, as were the sponges, followed by immersion in aseptic solutions. The sponges used were all new.

The patient was placed upon the table and chloroform adminstered. An incision was made in the median line from two inches above the umbilicus to within two inches of the pubes. There was no adipose tissue, and the abdominal wall was stretched to a degree of thinness that was remarkable.

The peritonæum was then incised, when the uterus loomed up before us like an inflated balloon; as yet there was no hæmor-rhage to speak of. The upper end of the incision was extended to near the lower end of the sternum. The intestines were held back by hot flat sponges and the uterus was taken through the abdominal opening, cleansed, and surrounded by a warmed dental rubber dam, the cervix constricted by an elastic tubing tourniquet, and the abdomen drawn upward.

The uterus was enormously distended. I now hastily made an incision through its anterior wall at its middle third. Its walls were so thin that I either incised the membranes or else they ruptured as a result of their freedom from imprisonment. There was a rapid gush of waters. I enlarged the rent and could then see the child in utero. It was in a left lateral breech presentation, thighs flexed upon the abdomen, the feet at either side of the head.

I grasped the child by the feet and made a quick delivery; it gave a short cry. I hastily tied and severed the cord and gave the child to the nurses; it was resuscitated without much difficulty.

In opening the uterus, very fortunately I did not encounter the placents; this was now turned out, followed by considerable hæmorrhage, especially toward its cervical attachments.

The pulse at this time became very weak, and the patient showed marked evidence of shock. Hypodermic injections of brandy, nitroglycerin, and digitalis were given, which caused some revival; also of ergotine into the muscular walls of the uterus, which were flabby; hot sponges were held tightly over the seat of the bæmorrhage. I also aided contraction by grasping the uterus in my hands and giving digital compression. Contraction then took place nicely and bleeding ceased.

The uterine cavity was cleansed and washed with bichloride solution, hot, 1 to 2,000. The uterine incision was then hurriedly but carefully stitched with a double row of stitches—deep sutures not including the mucous coat—then a row of superficial ones; the peritoneum was welted in edge to edge; the stitches were of twisted silk and interrupted.

The woman was now turned on her left side and the abdominal cavity washed out with bichloride solution (1 to 4,000), the cavity sponged dry. The uterus was then cleansed and replaced in its former position.

The abdominal wall was closely sutured, cleansed, dressed with carbolized gauze and absorbent cotton, over which was placed a many-tailed bandage. The woman was now placed in a warmed bed, surrounded by hot-water bottles; she soon came from under the anæsthesia, and retched once or twice, but there was no vomiting.

The pulse for the first twenty-four hours remained at 150; no pain; some orine voided; temperature normal. Liquid diet for twenty days, mostly hot milk, was given. The dressings were changed on the eighth day and stitches removed from abdomen. The wound healed by first intention.

The temperature ranged from 99° to 108.5°, its highest point, which was on the twentieth day. There was considerable discharge per caginam, slimy, dark, and very offensive. Vaginal carbolized douches were given every six hours. On this day I made a vaginal examination. Pushing two fingers forcibly through the opening in the hymen, I discovered a soft mass lodged behind it; removing it piecemeal, it proved to be brokendown putrid tissue, the odor from which was something terrible.

As the placenta had been cleanly removed, I looked upon it as uterine sloughing. About half a pound was thus removed.

The patient now went on to more rapid recovery. Full diet was granted on the twenty-first day. On January 31, 1894, she sat up, dressed. On February 2d she took a few steps, and now went on to complete recovery of her usual health.

There was no lacteal secretion, and the child, which at delivery weighed eleven pounds, has thrived nicely on cow's milk. Now (April 4, 1894) the mother has fully recovered her health and the child is growing well.

## A METHOD OF DIFFERENTIAL DIAGNOSIS IN STRICTURE OF THE ŒSOPHAGUS,

WITH REPORT OF TWO CASES.\*

BY HOWARD LILIENTHAL, M. D., ASSISTANT SURGEON TO MOUNT SINAI HOSPITAL.

S. J. P., aged fifty-seven years, an American by birth and a farmer and surveyor by occupation, consulted me on May 8, 1891, regarding a difficulty in keeping down solids and liquids which had been apparently swallowed. He had first become aware of this defect seven years before, when he discovered that he could no longer drink from a brook by lying down and putting his lips to the water. As he expressed it, he had to fill his mouth with the liquid and then, throwing back his head, allow it to run down his throat, thus drinking by stages "like the chickens." Later he found that when he lowered his head, as in stooping to pick up a fallen object, fluid would regurgitate together with solid masses of food thought to have been swallowed hours before.

The patient knew of nothing in his personal or family history which could throw light on the case. He said he had not had syphilis, nor did he remember any unusual irritation or injury to his alimentary tract.

For several years he had been treated by various medical men without improvement, and, as far as he knew, without a diagnosis. Some weeks before I saw him he came to New York, and was in the hands of a specialist, who said that the difficulty was reflex in character, and who accordingly repeatedly cauterized the mucous membrane of patient's nasal passages. There was no improvement.

On examination, I found the man to be superficially normal.

<sup>\*</sup> Read before the Section in General Surgery of the New York Academy of Medicine, February 27, 1894.

He was about six feet in height, and was rather spare and wiry. Although one could not call him emaciated, he informed me that he had lost thirty or forty pounds in weight.

Physical examination was negative, care being especially taken in palpation of the abdomen.

I now requested the man to swallow a glass of water, which he did apparently with ease. He then bent forward until his head was about two feet from the floor, when most of the water ran out of his mouth. There was also some mucus and saliva.

My conclusion was that there existed either a stricture of the gullet with dilatation above, or that there was a diverticulum.

Auscultation during swallowing revealed nothing.

The attempt to pass a medium-sized whalebone esophageal bougie failed, and a much smaller instrument was arrested at the same point, nine inches and a quarter from the front teeth.

The following day, after a half hour's patient work, a filiform urethral guide passed into the stomach. This I followed by a larger instrument, and so on until a No. 11 French urethral catheter of woven silk was reached. This catheter, though it engaged tightly, was successfully passed. There was no bleeding.

In order to make sure that the case was really one of stricture, and in order to exclude the possibility of diverticulum with a small opening into which my instrument might have passed, and to exclude as well regurgitation from the gastric cavity itself, the following method, which I believe to be original, was employed:

The patient having fasted for six hours, the No. 11 French catheter was again with difficulty introduced. Three ounces of water, very deeply colored with methyl violet, were injected with a hand syringe into the catheter, immediately followed by three ounces of clear water. The catheter was then withdrawn. The patient now drank a glass of water, and in a few moments, at my request, caused its regurgitation by lowering his head. The water returned absolutely unstained. He then drank a glass of slightly stained water, and the stained water returned unchanged in color.

By gradual dilatation with woven urethral instruments passed daily, the stricture widened to No. 15 French. The man's condition and ability to swallow greatly improved. Although there was no evidence of syphilis, I ordered iodide of potassium, in twenty-grain doses, thrice daily.

In less than a week my patient was obliged to return to his home in the northern part of the State. He had learned to put the instruments into his œsophagus, and he took with him a number of olive-tipped bougies of various sizes. Two months later he reported himself by mail as still doing well, and on October 22, 1892, nearly a year and a half after I saw him, he wrote me that, though there was still an obstruction, he could live as he had always lived, could stand long tramps, and could sleep upon the ground as well as ever. Formerly the collection of mucus, saliva, and food in his esophagus had regurgitated and made it impossible for him to sleep upon the ground-i.e., with his head low. He had regained his weight, and had "never been any better" in his life. A letter, dated February 22, 1894, states that the patient has stopped the iodide, and has for a long time ceased to put the bougies into his gullet. He feels well and can eat, but there is still an obstruction present.

It has been my fortune to try this diasgnotic method in another case. An old man in the service of Dr. Manges at Mount Sinai Hospital last summer had an obstruction in swallowing and a constant tendency to vomit. The œsophageal instruments of the hospital could not be passed into the man's stomach. Dr. Manges very kindly gave me the oppor-

tunity to make an examination, which was done in his presence. A very fine catheter (No. 8 French, I think), to which a rubber tube had been attached, was passed into the stomach. The obstruction was found to be about fifteen inches from the front teeth. After the injection of the aniline color, the patient, with much spasmodic effort, vomited a little mucus in which were very small splashes of the violet, each splash corresponding, I thought, to an effort at vomiting. Accordingly, a diagnosis of tight stricture near the stomach was made, and, for this and other reasons, gastrostomy was proposed. This the man declined. Shortly afterward he died, and the autopsy revealed cancer of the cardia with tight stricture.

33 East Thirty-first Street, New York.

#### ABDOMINAL SECTION.

H.EMORRHAGIC DIATHESIS; RECOVERY.

By R. STANSBURY SUTTON, M.D.,

ALLEGHENY, PA.,
SURGEON TO TERRACE BANK HOSPITAL FOR WOMEN;
GYNLECOLOGIST TO THE ALLEGHENY GENERAL HOSPITAL

On February 1, 1893, Miss M. presented herself, saying that she had an abdominal tumor. She was twenty-four years old, very ansemic, with a thin, rapid pulse; she had suffered a great deal of pain, and her menstrual attacks were irregular and profuse. A few weeks before this interview she had a tooth extracted, and bled more or less for several days, despite various efforts to arrest the bleeding. She had frequent and alarming attacks of epistaxis; rapid walking was painful, and provoked severe dyspnea. The object of her interview with me was to know if I thought it was possible to take her tumor out and not kill her. I gave her a doubtful prognosis, at which she was evidently displeased. Her persistency, despite the opinion, led me to give her a permit to the Allegheny General Hospital.

On February 6th, an attack of epistaxis having occurred since she got the permit, A. C. E. mixture was administered by Dr. Corbus; she was in the Trendelenburg posture, with high elevation. With great rapidity I removed two ovarian cysts, one of which was adherent in the pelvis; the posterior surface of the uterus and left wall of the true pelvis were left raw, and the bleeding was persistent. A few hot sponges were packed in tightly, but made little impression upon it. I caught at its middle point a handkerchief, eighteen inches square, of iodoform gauze, with the sponge forceps, and carried the caught point to the bottom of Douglas's cul de sac. Into the funnel thus made, I thrust handkerchiefs of iodoform gauze until the true pelvis was packed full; the free ends of the handkerchief forming the funnel or bag, were gathered together in the lower angle of the wound. Above these the wound was closed with interrupted sutures, placed four to the inch. Over the scaphoid belly, and particularly over the entrance to the pelvis, close to the pubic symphysis, a large mass of absorbent cotton was placed, and firmly pressed down upon the intestines and intrapelvic packing with a scultitus bandage.

With but little pulse she was put to bed, head downward, on an inclined plane formed of the hair mattress. Trinitrin and brandy were given with the hypodermic syringe; she rallied in a few hours.

Thirty-six hours after the operation a little chloroform was given; I reopened the wound, took out the Mikulicz packing, and reclosed the wound in its entire length this time. During her convalescence she had repeated attacks of epistaxis, which

were controlled by plugging the posterior nares. Finally she recovered, and has improved in health.

It is now several months since I have heard of her.

I have occasionally resorted to this method of arresting intrapelvic bleeding. More than once I have left hæmostatic forceps protruding from the lower angle of the wound for forty hours after an operation. In all such cases the patients have recovered.

Where the bleeding has resisted sponges wrung out of very hot water, or the hot water in a stream upon the bleeding surface, I have frequently put in a drain-tube, closed the wound, and resorted to a large cotton compress firmly held down with the Scultetus bandage. Where there is no marked constitutional cause, or predisposition to hæmorrhage, the presence of the drain-tube has at once proved that this method is reliable.

Where a bleeding vessel is so deep in the pelvis that it can only be secured by a catch-forceps, and the latter is not long enough to reach through the wound at its lower angle, a silk ligature should be tied to the forceps and be brought out of the lower angle of the wound. Thirty-six hours later the forceps should be removed; the silk ligature is a reliable guide to its location.

#### A NEW OPERATION FOR CONGENITAL HERNIA.

By H. T. GOODWIN, M.D.,

LOUISVILLE, KY..
PASSED ASSISTANT SURGEON, U. S. MARINE HOSPITAL SERVICE.

PASSED ASSISTANT SURGEON, U. S. MARINE HOSPITAL SERVICE

A LITTLE more than a year ago a patient, nearly forty years of age, presented himself to me for an operation for the radical cure of a congenital hernia which descended well into the scrotum, and there formed a tumor about twice the size of a hen's egg. It had grown rapidly during the last three months, but before that had given him no trouble whatever.

This is a common enough history, and the case would not be worth reporting but for the fact that I desire to call attention to the operation I performed—an operation easy of execution, simple, far safer than opening into the sac, and which, so far as I am aware, had never before been done, or if done had never been reported by any surgeon.

I have operated in all about twenty-five times for the radical cure of hernia, including several of the congenital form, and though my results have been very satisfactory in a large percentage of the cases, I have never had one with a recovery apparently more perfect than this. As it is scarcely fair, however, to judge of the merits of any operation by the result obtained in a single case, I shall be glad to hear if other surgeons, who may be sufficiently favorably impressed with the operation to adopt the procedure, obtain equally good results.

The steps of the operation, up to the exposure of the sac, were the same as in ordinary operations. At this point I drew the sac well out, and after carefully pushing back the contents through the abdominal opening, and holding up the sac before the light to make sure that nothing remained in it, I gently grasped the testicle and cord between the fingers and thumb of my left hand, while with my right I caught up the upper surface and put the entire sac on the stretch in the same manner

that one would pull laterally on a glove to make it wider. then gave it into the hands of an assistant to hold in the same manner, and while he kept it on the stretch I took a catgut suture armed with a needle at each end, and commencing at the lower border of the sac put in a row of saddler's sutures, taking care to hug the testicle and cord as closely as consistent with safety. The sutures were continued up sufficiently high to reach just within the internal ring when the parts should be returned to their normal position. With a pair of scissors I followed closely along the line of sutures and cut off the redundant portion-i. e., that part of the sac which had been separated from the testicle and cord by the sutures. Then with another catgut suture I made a whipped stitch over the borders so as to bring the raw edges of the sac into apposition. The pillars of the rings were brought together, leaving an opening only sufficiently large to admit of the safe passage of the cord now contained in the greatly reduced tunica. The subsequent steps were the same as in other operations of the kind.

The patient never had the slightest rise of temperature, and when a week later the dressings were removed the wound was found healed.

The operation was performed in the United States Marine Hospital, Stapleton, Staten Island.

LOUISVILLE, KY., March 14, 1894.

#### A CASE OF

#### SYPHILIS HÆMORRHAGICA NEONATORUM.

BY WILLIAM E. CONROY, M. D., SAGINAW, MICH.

I REPORT the following case with considerable minuteness of detail on account of the rarity of this peculiar manifestation of congenital syphilis. Bumstead and Taylor, writing in 1883, state that only sixteen cases were then recorded in literature, adding an account of two more which happened in their own experience. Abner Post, in Keating's Encyclopædia of Children's Diseases, says that "Dr. Uraceck has reported (Deutsch, Med.-Zeit.) a series of peculiar hæmorrhages of different internal organs. Out of a hundred and thirty-two deaths among children of syphilitic mothers slight hæmorrhages were distinguished in forty-four cases. There were only nineteen cases, however, in which the positive diagnosis of syphilis could be made. Of these children, eighteen came into the world alive, but none lived very long, and ten died within a quarter of an hour."

In my case there can, I think, be no doubt of the diagnosis, though this variety of congenital syphilis has usually occurred, as Post remarks, in families more recently syphilitic. It is also unusual for hæmorrhagic lues to affect the child of an untainted mother, inheriting the disease from the father alone. But the symptoms were unmistakable, resembling those found in no other disease except that rare form of small-pox known as variola pustulosa hæmorrhagica, which, of course, was out of the question. Another strong point was the death of the former child from convulsions accompanied by an eruptive skin disease.

Mrs. H., aged twenty one years, United States. Family history good. Has never been seriously ill. Gave birth in 1892 to a female child which died seven weeks after birth, in convulsions. When a few days old "pimples" broke out on its

skin. Has had no miscarriages. Health during the present pregnancy has been excellent. Urine free from albumin and sugar. No ædema of extremities. Admitted to Saginaw Hospital, December 15, 1893. After a perfectly normal labor of about five hours' duration, patient gave birth to a female child at 5 a. m., December 29th. The placenta appeared to be normal. No after complications worthy of record.

The child at birth seemed well developed and vigorous. Skin smooth and free from eruptions. The conjunctival culs-desac were washed out with Credé's solution. Immediately after being washed and dressed the baby went to sleep and slept until evening, when it was put to the mother's breast (mammary glands large and distended with milk). It refused to nurse, however, and again went to sleep.

December 30th.—Frequent attempts were made to induce the child to suckle, but without success, though examination of the mouth revealed nothing to account for this, the mucous membrane being intact and the frenum of average length. The mother's milk was therefore given with a spoon. About noon the baby became restless, sneezed several times, and during the afternoon and evening cried occasionally. Bowels moved toward evening and the napkins showed that urine had passed, though scantily. Sleep much disturbed during the night, baby very uneasy, and crying much, as if in pain. Bowels moved again before morning.

December 31st.—Baby fidgeted and cried almost constantly this morning. Rectal temperature at 6 a.m., 104°; respirations, 70 per minute. Bowels moved several times; passages greenish, frothy, and offensive. Urine scanty. Temperature at 12 m., 103°; respirations, 58. Several pustules appeared at about noon (fifty-five hours after birth) on the neck, rapidly increasing in number and extending to the face, head, and shoulders. When these pustules were opened or ruptured spontaneously, they immediately filled with dark blood. Six P. M., temperature, 103°. Child slept very little during the night, awakening frequently with sharp cries.

January 1, 1894.—At 2 a.m. about a drachm of dark blood, mixed with a little pus, was discharged from the right ear, after which the child was quieter for some time. At 6 a.m., temperature, 102.4°; respirations, 50. During the day there were hæmorrhages from the nose, vagina, and rectum, also subconjunctival ecchymoses, and bloody urine. Constant and copious discharge of bloody pus from the right ear. At 5 p.m., temperature, 102°. Toward evening the baby vomited about three drachms of dark blood. Very restless during the night. Frequent sharp cries. Bleeding at intervals from all mucous surfaces and into pustules. Left side of head swollen and addematous.

January 2d.—Condition unchanged. Temperature varies from 101° to 102°. Ilæmorrhages continue at intervals, and fresh pustules form, which soon fill with blood. Stools very offensive.

January 3d.—At 10 A.M. the child suffered from a convulsion, becoming rigid and cyanosed, bloody froth issuing from the mouth; temperature, 100.8°. Slighter spasmodic attacks occurred during the day, the hæmorrhages continued, and the child died in convulsion at 11 P.M.

As soon as the character of the disease became apparent, I obtained from the mother the information that her husband had contracted syphilis before their marriage, but had never since then shown any evidence of disease. The man himself afterward told me that about eight years previously he had become infected, but that the symptoms had been very slight and evanescent, and that he had con-

sidered himself oured, since for seven years he had noticed no evidence of the disease. He is spare and anæmic, but presents no appearance of syphilitic or other dyscrasia.

It is worthy of note that in this case there was not bleeding from the umbilicus, the usual seat of hæmorrhage in the newborn, nor were there mucous plaques about the anus, coryza, or any of the more customary symptoms of congenital syphilis. The case also offers the strongest possible proof of the persistent tenacity with which this disease is apt to lurk in the system, lulling its victim to a false security, only to appear in all its hideousness in the person of his innocent child.

I omitted to state that as soon as the pustular eruption appeared mercurial inunctions were employed, but without the slightest apparent effect.

#### HYPOCHONDRIA.

#### By SAMUEL GOLDBERG, M. D.

On February 8, 1893, Mr. A. A., aged thirty years, married three years, no children, native of Russia, carpenter by trade, was brought to my office by his father, who said the patient had become insane about four months previously; had been under treatment all that time with no apparent results, and requested me to take charge of the case. He informed me that the patient had not slept for a week or so, but would walk the floor at night muttering to himself, or, becoming boisterous, would declare that his wife did not love him, and while in this condition he would break the furniture, throw the dishes out of the window, and threaten to commit suicide. He had not eaten for quite a long time, asserting the food was poisoned. On physical examination, I found him anemic, with the characteristic blank expression of the eyes; he also was constipated (had not had a passage for five days); he had continual headaches and flatulency; he was very feeble; pulse, 101; tongue thickly coated and dry; breath very offensive with the starvation odor, due to his abstinence from food, and stating that he felt heavy in the stomach, as if something was in it. The first time he was brought to my office he complained to me that his family and friends were tired of him, that they wanted to kill him, etc. The rest of the family's history was negative. At his first visit I prescribed:

R Emul. ol. ricini, fifty per cent...... 3 iij. Sig.: One dose.

With instructions if this did not act during the day he should be given a rectal injection of warm water and castile soap in the evening. I also prescribed:

R Morph, sulph. . . . . gr. ½. Pil. no. vj.

Sig.: One every half hour till sleep follows.

At noon the following day his father called and stated that after taking five pills the patient fell asleep and slept from 11 P. M. till nine the following morning. The emulsion did not have the desired effect, so he gave him the warm-water injection and obtained the result. I then prescribed:

$\mathbf{R}$	Potass, brom., )
	Tinct. gelsem
	Syr. simp
	Aquæq. s. 3 iij.

M. Sig.: One drachm four times a day.

On the 15th the patient again called with his father and

stated that the headache had left him, but the distressed feeling in the stomach continued. I then prescribed:

Ŗ.	Potass brom	3 ij;
	Tinct. gelsem	3j;
	Syr. simp	ξj;
	Λquæ	ʒ iij.
M. S	ig.: One drachm four times a day.	
	gave him:	
$\mathbf{R}$	Sodii bicarb	
	Pepsin	
	Pulv. nux. vom., /	gr. j.

Pulv. ipecac., M. et div. cap. no. viij.

Sig.: One four times a day.

I ordered him to take no solid foods.

On the 25th he returned. No distressed feeling in the stomach, appetite improved, but neuralgic pains in the head. I again prescribed the bromide of potassium and gelsemium, and also gave him:

R Nickel sulph..... gr. 1.

Pil. no. viij.

Sig.: One every three hours.

On March 2d he reports having passed several restless nights, no pain, appetite not very good. I did not change the treatment.

March 10th.—No pains of any kind, sleeps well, but appetite very poor. I then gave him syr. hypophos. comp. (Fellows) and pepto-mangan. (Gudes), on which I kept him for two months. I discharged him as cured May 15, 1893, and since then he has not been troubled, but attends to his business daily.

On the subject of melancholia Spitzka's work on insanity, page 147, says: The duration of melancholia may comprise weeks, months, or years. The average duration is from three to eight months. The frequency is difficult to determine, as a large number of the patients never reach the asylum, but recover, die, or commit suicide outside its walls. Of 2,297 admissions to the pauper insane asylum for males of New York city, 301, or a little over thirteen per cent., were cases of melancholia. Of 1,193 patients of both sexes admitted to the reception wards of Professor Meynert, not quite six per cent. were melancholiacs. The greater frequency of melancholia with females, which is in part attributed to the influence of prolonged lactation, pregnancy, exhausting discharges, and chloro-anæmia in provoking this psychosis, is illustrated by the statistics of the Budapesth asylum. Here ten per cent. of the male and seventeen per cent. of the female patients suffered from melancholia. Of 146 males received at Feldhof by Krafft-Ebing, 13, or nearly seven per cent., were melancholiacs, while of 121 females, 18, or nearly fifteen per cent., suffered from the same disease.

In the writer's statistics the striking fact is noticeable that melancholia is most frequent in the Teutonic people, the ones who, according to Morselli, also show the highest suicidal ratio; and among these it was found more frequent with those who had immigrated than with those who had been born in this country.

248 EAST BROADWAY, NEW YORK.

Change of Address.—Dr. Leopold Stieglitz, to No. 571 Park Avenue. THE

## NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by

Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, APRIL 21, 1894.

THE CENTRALIZATION OF SANITARY WORK.

It seems that it is not in the United States alone that the cry goes up for a national sanitary official. In almost the very words that have been used here, Dr. T. G. Nasmyth, the medical officer of health for Fife and Clackmannan, in Scotland, calls for such an official and prophesies that in a few years the State will show its interest in State medicine and public health by the appointment of a cabinet minister to preside over the various central boards in Great Britain and Ireland. This prophecy we find in a presidential address delivered by Dr. Nasmyth before the Fife Medical Association and published in the April number of the Edinburgh Medical Journal.

He argues that the whole history of such diseases as small-pox, cholera, yellow fever, and influenza shows their ubiquitous nature, their world-wide distribution, their "epidemic expansiveness"; they are not confined to any one country, far less to one city or village, but are at work all over the world. Consequently individual efforts, even local organized efforts, can do little or nothing to prevent the spread of such diseases; international action should be taken at times—"State must act with State," says Dr. Nasmyth, "and the greater the areas included in their consideration the more hope there is of the repression of epidemic diseases." He reminded his hearers of their daily visits to the bedsides of the sick, telling of the blessings of pure air, pure water, and cleanliness, and saying, in the words of Charles Kingsley, "You, and not 'the visitation of God,' are the cause of epidemics."

What advances have thus far been made in the science of public health, he says, have been due to medical discovery and teaching, and he thinks that all the signs of the times point to advances of still greater importance in the domains of physiology, chemistry, and pathology, so that a nation can not much longer allow investigations and discoveries to be the efforts of private individuals, notwithstanding the fact that at all times there have been found in the medical profession unpaid workers and pioneers to make such efforts.

Assuredly the agitation that has sprung up in favor of more or less centralization of sanitary work, advisory, if not executive, can not be allayed, can not be kept from gathering force as time goes on; it is not members of the medical profession alone who join in it, for all well-instructed citizens, when they have once been brought to see the advantage of concerted action in the fight against preventable disease, are ready to promote it. There is no question of the need of central supervision; the only question is as to the best scheme for carrying it out. Various measures have been proposed in Congress, as our

readers are quite aware, but most of them have seemed to be objectionable to a greater or lesser extent. We must, however, repeat what we lately said of the New York Academy of Medicine's latest bill, that it seems feasible in its execution and promising as to its results, provided it receives such amendments as to non-essential matters as we have already pointed out the need of, and as must, we feel convinced, meet with the approval of all who desire really satisfactory legislation.

#### THE FOUR HUNDREDTH ANNIVERSARY OF THE BIRTH OF PARACELSUS.

In the March number of the Revue de chirurgie there is a short sketch of this remarkable man by M. Nicaise, who remarks that the recent anniversary seemed to him a fitting occasion on which to recall the memory of a man who occupied so conspicuous a place in the beginning of the sixteenth century. Paracelsus was a singular mixture, and not a man to be easily appreciated. He had many admirers, but was very severely judged by his contemporaries as well as by those of later days. It was his boast that he had not learned medicine and surgery from books, that he did not follow the teachings of renowned physicians and surgeons. Such study, says M. Nicaise, was not congenial to a man of his temperament; it was too slow. But he had acquired a certain knowledge, owing to his keen intelligence, to his observations, and to his travels.

He rejected all the current doctrines, and sought to found a new one; in fact, he acted like a daring empiric, writing and doing the most extraordinary and, the greater part of the time, incomprehensible things. At the same time, he was a man with ideas far in advance of the age, and he combated and discarded the antiquated theories then in vogue and showed the importance of chemistry; he also brought forward improvements in the preparation of drugs. In his writings, Paracelsus thus alluded to the superstitious spirit of the age: "According to the common people, all diseases not of external or surgical origin are diseases without cause—that is, they are sent from God or the saints. Against these the physician can do nothing, unless he is one of those supposed to be peculiarly endowed to cure such diseases-in other words, a charlatan. These men declare that they are empowered through divine inspiration to cure such diseases, and they treat their patients with holy water, prayers, secret remedies, and other devices in such a manner as to impress them with the belief that they operate by the grace of God." Although Paracelsus thus attacked the charlatans, he was not altogether free from the superstitions of his time, for he held that medicine was a science revealed to some privileged persons, and that only those could restore health to whom the knowledge of an insight into human nature had been given by God. He declared that he had received this knowledge himself and that his medicines were the only good and useful ones.

Paracelsus rejected the doctrine of humors; it was for him only the product of the imagination of the followers of Hippocbut a vague theory for their foundation. He believed that all elements (fire, earth, water, and air) were divided into three parts-salt or balsam, rosin or sulphur, and the spirituous part or gotaronium (mercury). The words salt, sulphur, and mercury did not correspond to any real substances; they were purely imaginary. From all that, says M. Nicaise, it was more difficult to deduce anything than from the theory of humors. and this new doctrine of the three elements Paracelsus had borrowed from Basil Valentin.

With regard to wounds, he rejected the suture, contending that Nature reunited them little by little owing to the natural balsam contained in the body, a balsam which varied in each part; he rejected also the theory of immediate reunion, declaring that secondary union was the one needed. He spurned the use of digestives and suppuratives, and recommended desiccatives and washing the wounds with vinegar of roses; he employed glutinative powders and waters, oils or vulnerary unguents, and afterward plasters. In fractures he did not use splints or cushions, but replaced them with two rings of variable diameter, joined by vertical shafts. In surgery he contented himself with employing topical applications and internal medicines, and condemned the use of caustics and the general use of the cautery, and did not resort to instruments.

Paracelsus was an enthusiast, believing himself called to be a great reformer, aspiring to be the Luther of medicine, but, as he was a man of little education, wanting in patience and perseverance in the study of medicine, in fact, in everything conducive to the realization of a grand purpose, he founded nothing. One can understand, however, says M. Nicaise, that, with such qualities, and even such faults, with his daring and his absolute confidence in himself, he made a strong impression, especially in the epoch in which he lived.

#### MINOR PARAGRAPHS.

#### THE ROME CONGRESS.

Accounts have reached us of gross mismanagement of the Eleventh International Medical Congress. A correspondent writes that for the first two days it simply was not managed at all, and everything was in confusion. The obstetrical section, he adds, posted notices of a hundred and twenty-four papers to be gone through with in a single day-in itself an absurd thing to do-and then adjourned early on that day, leaving the papers unread. But something worse than confusion is chargednamely, that the Italians were rude to the Americans and Englishmen present, ostentatiously withdrawing their attention when those who spoke in English had the floor and distracting the attention of others by making noises. The sound of the English language, indeed, seemed to offend them. The next congress is to be held in Russia, where, it is to be expected, English will not be thought offensive.

#### STRONTIUM BROMIDE IN ACUTE CATARRH OF THE STOMACH.

The Lyon médical quotes from the Tribune médicale a reference to clinical trials of this salt by Dr. Carselli, of Palermo, rates. The names bile, melancholy, phlegm, and blood had in gastric affections, especially acute catarrh, which, it says, show anew the remarkably favorable action of the drug. Carselli uses a syrup made by dissolving thirty grains of strontium bromide in a mixture of a fluidounce of syrup of bitter-orange peel and three fluidounces and a half of distilled lettuce-water. This amount is to be taken daily in three doses, during and after meals. It stops the vomiting and lessens the pain. It is thought to act both directly upon the nervous system and as an antiseptic, arresting fermentation and thereby reducing the flatulent distention that gives rise to the pain.

## THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

The congress which is to be held in Washington on May 29th, 30th, and 31st and June 1st has every prospect, judging from present appearances, of proving even more satisfactory than any of its predecessors. In the first place, Washington is apt to be much more comfortable early in the summer than early in the autumn, when such meetings have heretofore been held there. Much energy has been displayed by those who are charged with the arrangements, and it is to be expected that the debates will be conducted in a manner best calculated to insure thoroughness and at the same time guard against prosiness. The programme for the general sessions was published in our issue for February 24th. Those of the various constituent societies will, it is to be presumed, be issued soon. There will, we think, be more than the usual attractiveness to the congress this year.

#### BROWN-SÉQUARD'S AMERICAN JOURNAL,

The British Medical Journal makes the erroneous statement that during his residence in New York the late Professor Brown-Séquard founded the Archives de médecine scientifique et pratique. The fact is that the journal, title and all, was printed in English, and it was called the Archives of Medicine.

#### ITEMS, ETC.

The D. Hayes Agnew Memorial Committee, organized a year ago to secure a lasting memorial of Dr. Agnew in connection with the University Hospital, Philadelphia, report that subscriptions have been promised of sufficient amount to give reasonable assurance of the speedy and successful carrying out of the project. The plan includes not only the children's ward (for the building of which an associate committee was established and for which it is earnestly laboring), but also an amphitheater and ward class rooms, with wards for men and for women-the whole to be a model in perfection of details and completeness of appliances, and thus a fitting representation of the wonderfully full and complete work of Dr. Agnew. The State Legislature, at its last session, made an appropriation of \$80,000 to the University Hospital for building purposes, provided that an equal sum of \$80,000 be raised by the friends of the hospital, and paid in cash, available for construction purposes. The managers of the hospital, appreciating the eminent propriety of the movement, have consented to give to the entire wing the honored name of D. Hayes Agnew. Toward the additional \$80,000 to be so raised, about \$60,000 can now be counted upon as available in cash on or before May 1, 1894, leaving only about \$20,000 more to be secured by that time, so that building operations may begin this spring, and the State appropriation be drawn and expended within the two years contemplated in the act. It is to be hoped that, in addition to the building fund, there may also be secured a sum sufficient for the beginning of an endowment. Such a memorial will best attest the affection

inspired by Dr. Agnew's life of usefulness and the example of devotion to his profession both as teacher and as practitioner. The grant by the Legislature is a recognition of the work done by the university and its hospital, to which Dr. Agnew gave the best years of his busy life, and the subscription supplementing and securing that appropriation will show how his many friends, patients, and students honor his memory. All those who desire to join in this memorial of a great surgeon and good man can do so by sending their subscriptions to the treasurer, Mr. Eugene Delano, of Messrs. Brown Brothers, at the banking house, southeast corner of Fourth and Chestnut Streets, Philadelphia.

The Death of Dr. Corydon L. Ford, of Ann Arbor, professor of anatomy in the University of Michigan, is announced to have occurred on Saturday, the 14th inst. During his long professional career he was a wonderfully effective and popular teacher of anatomy, of which he was professor in various colleges at different times, sometimes in more than one college at the same time. He was a graduate of the Geneva (N. Y.) Medical College. He was eighty-one years old.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 8 to April 14, 1894:

So much of Par. 13, S. O. No. 79, A. G. O., as relates to Cleary, Peter J. A., Major and Surgeon, is so amended as to direct him, on being relieved from duty at Fort McPherson, Georgia, to report for duty at Fort Wingate, New Mexico, instead of Fort Custer, Montana, for duty at that post, to relieve Matthews, Washington, Major and Surgeon. Major Matthews, on being so relieved, will repair to Washington city and report in person to the Surgeon General for temporary duty in his office.

Par. 2, S. O. No. 68, A. G. O., is so amended as to direct Mo-VAY, HARLAN E., First Lieutenant and Assistant Surgeon, on being relieved from duty at San Carlos, Arizona Territory, by Straub, Paul F., First Lieutenant and Assistant Surgeon, to report for duty at Angel Island, California, instead of Fort Huachuca, Arizona Territory.

RAFFERTY, OGDEN, Captain and Assistant Surgeon, is hereby granted leave of absence for one month, with permission to apply for an extension until the 20th of May next.

The following-named officers of the Medical Department will report in person for temporary duty until further orders as follows:

Willoox, Charles, First Lieutenant and Assistant Surgeon, to the commanding officer, Angel Island, California.

Flage, Charles E. B., First Lieutenant and Assistant Surgeon, to the commanding officer, Alcatraz Island, California.

#### Society Meetings for the Coming Week:

MONDAY, April 23d: Medical Society of the County of New York; Boston Society for Medical Improvement; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

Tuesday, April 24th: Texas State Medical Association (first day—Austin); New York Academy of Medicine (Section in Laryngology and Rhinology); New York Dermatological Society (private); Buffalo, N. Y., Obstetrical Society; Medical Society of the County of Putnam (quarterly), N. Y.; Hunterdon, N. J., County Medical Society (Flemington); Litchfield, Conn., County Medical Society (semi-annual); Boston Society of Medical Sciences (private).

Wednesday, April 25th: Texas State Medical Association (second day); New York Surgical Society; New York Pathological Society; American Microscopical Society of the City of New York; Mctropolitan Medical Society (private), New York; Medical Society of the County of Albany, N.Y.; Auburn, N.Y., City Medical Association; Berkshire, Mass., District Medical Society (annual—Pittsfield); Philadelphia County Medical Society.

Thursday, April 26th: Medical and Chirurgical Faculty of Maryland (first day—Baltimore); Texas State Medical Association (third day); New York Academy of Medicine (Section in Obstetrics and Gynæcology); New York Orthopædic Society; Brooklyn Pathological Society; Roxbury, Mass., Society for Medical Improvement (private); Hartford, Conn., Medical Association (annual); Pathological Society of Philadelphia.

FRIDAY, April 27th: Medical and Chirurgical Faculty of Maryland (second day); Yorkville Medical Association (private), New York; New York Society of German Physicians; New York Clinical Society (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, April 28th: Medical and Chirurgical Faculty of Maryland (third day); New York Medical and Surgical Society (private); Worcester, Mass., North District Medical Society (annual—Fitchburg).

## Letters to the Editor.

FRACTURED RIB AND DISLOCATED CLAVICLE AS A RESULT OF FITS OF VIOLENT COUGHING.

QUEBEC, April 16, 1894.

To the Editor of the New York Medical Journal:

Sir: In the number of the New York Medicul Journal for April 7th Dr. Schenck reports a case of fractured rib as a result of a violent fit of coughing. Such cases, while far from frequent, are not so rare as your correspondent seems to think. His communication prompts me to report the following case:

On September 3, 1879, Mrs. J. O'C., a strong, healthy womany was in labor with her third child. During a severe pain, accompanied by powerful expulsive efforts, she was seized with a violent fit of coughing. She suddenly applied her hand to her right side, and as soon as she could speak she said that something must have broken in her chest, as she heard a crack. On examination, I discovered a fracture of the sixth rib a little in front of the left anterior axillary line.

On Thursday, December 7, 1876, William Q., eighteen years of age, and in the last stage of phthisis pulmonalis, felt, during a violent fit of coughing, severe pain at the inner end of the right clavicle and found a lump there. This tumor disappeared on drawing his arms back, but reappeared at each severe fit of coughing. The lump was formed by the inner extremity of the right clavicle, which was dislocated forward.

M. J. AHERN, M. D.

## Proceedings of Societies.

SOCIETY OF THE ALUMNI OF BELLEVUE HOSPITAL.

Meeting of March 7, 1894.

The President, Dr. Frederick Holme Wiggin, in the Chair.

Charles Clifford Barrows reported such a case. A young wo-

man had been sent to him last August with a diagnosis of anteflexion of the uterus. No flexion had been found, but there had been a hydrops of the gall bladder. On operation, it had been found to be distended with bile, and had contained a large number of gallstones. The ducts and bladder had been carefully examined and it had been supposed that all the stones had been removed, but as an extra precaution a fistula had been made. There had been no fever following the operation. The patient's general condition had improved, but she had suffered from colicky pains from time to time. Sometimes large quantities of greenish bile had been discharged, and at other times the discharge would be perfectly transparent—a mucilaginous fluid, giving a scarcely perceptible biliary reaction. She had finally passed from under observation, and had come under the care of another physician, who, observing the transparent discharge, had thought there was a pancreatic fistula. The patient had been sent back to Dr. Barrows and had again been operated upon. A probe had detected a gallstone, and on operating the second time the stomach had been found adherent to the abdominal wall, the omentum adherent to the gall bladder and under surface of the liver, and the intestines about the gall bladder firmly bound together by adhesions. The various adhesions had been broken down and the gall bladder exposed and examined. It had undergone the usual atrophy. No gallstone had been found in the bladder, but in the common duct, just below the junction of the biliary and cystic duct, had been a stone lying in a pocket in the lower part of the cystic duct and the upper part of the common duct. The stone could be moved backward and forward in the pocket, sometimes occluding the cystic and at others the common duct. This had easily explained the intermittent discharge of bile. The stone had been broken up and removed with a pair of forceps. Examination after removal of the stone had shown that the wall of the common duct was considerably thickened and its caliber interfered with; hence, he had decided that it was safer to make an anastomosis between the intestine and the gall bladder. The adhesions about the duodenum had been so extensive that this part of the bowel could not be used, so a neighboring coil of intestine had been picked up, and by the salt test the proper direction had been ascertained. It had been determined that this portion of the bowel was about two feet from the duodenum. The gall bladder and intestine had been opened, a purse-string suture introduced in each, and the smallest size of Murphy's button applied and locked. The button had come away on the ninth day. The patient had made an uninterrupted recovery, the wound as well as the biliary fistula having healed under one dressing.

The speaker said that the operation with this button was simplicity itself, and there were now enough cases on record to show that the operation was safe as well as easy.

He called attention to the fact that although the patient, prior to the last operation, had had a biliary fistula from which the bile had been freely discharged, she had continued to suffer from the usual colicky pains. These pains had evidently been due to the presence of the calculus in the duct. He therefore advised that in all cases the bladder and ducts be freed from calculi before the button was inserted. This was contrary to the advice of the originator of the method, who made no effort to remove the calculi, assuming that they would find their way into the intestine; but the present case illustrated the wisdom of removing all the calculi.

Dr. J. F. Erdman said that it was very difficult to pick up the duodenum even when there were no adhesions. The easiest way to find the duodenum under these circumstances, judging from his experience in the dissecting room, was to pick up the first portion of the small intestine which appeared to be bound firmly to the posterior abdominal wall, as this was, as a rule, the point of termination of the duodenum and the beginning of the jejunum. Of course, where there were extensive adbesions this would not apply. He had performed on a dog the operation of end-to-end anastomosis, and from the time of beginning the anæsthetic to the completion of sewing up the abdominal wall the operation had taken fifteen minutes.

(To be concluded.)

#### PHILADELPHIA ACADEMY OF SURGERY.

Meeting of March 5, 1894.

The President, Dr. WILLIAM HUNT, in the Chair.

Left Inguinal Colotomy .- Dr. JOHN H. PACKARD read a paper in which he said that by some surgical writers, notably the elder Gross, the opinion had been expressed that the making of an artificial anus by opening the colon placed the patient in a condition so distressing that death itself would be preferable. His own experience with these operations warranted him in upholding a very different view. His first case had occurred in 1873, and he had had the advantage of the presence and assistance of Professor Gross and of Dr. Levis. The patient, whose rectum had been occluded by a uterine cancer, had lived in comfort for eight months, and then died from exhaustion due to the advance of the disease. In this instance, and in other cases for many years afterward, he had made the opening in the left loin, thinking the access more ready, and preferring to avoid encroaching upon the peritonæum. There was, however, one great objection to the method, that the point of exit for the fæces was so placed as to be only with difficulty reached by the patient, and to require the assistance of others in attending to it.

For the operation in the left groin, he thought the best rule as to the incision was to make it just as on the right side in appendicitis, an inch and a half from the left anterior superior iliac spine, and at right angles with a line between this process and the umbilious. With scrupulous asepsis the opening of the peritoneum was made with safety; the operation was one of no more difficulty than that in the loin, and the artificial anus was entirely under the patient's control. The directions given in some of the books for the finding of the bowel seemed to him to be needlessly complex; if the large intestine did not immediately present itself in the wound, a portion of the small intestine would, and must be pushed aside, when the sigmoid flexure, especially if distended, would be seen, and might be recognized by the longitudinal muscular bands. own opinion was that it was a matter of but little moment whether the bowel was opened at once or after the lapse of several days.

He thought it important that the gut should be well drawn down into the wound until the portion above this point was slightly tense, so as to avoid subsequent prolapse through the artificial anus. Even with this precaution it sometimes happened that the inner wall would pouch out and be a cause of some annovance.

For suturing the edges of the peritonæum to those of the skin it was well to use black silk, so that these stitches might be readily distinguished from those by which the bowel itself was fastened in the wound; these latter should be of white silk, and should penetrate beyond the muscular coat, but not through the mucous membrane.

It was not always easy to judge how large an opening should be made into the bowel. In a child, or when the

wall of the gut was very thin, a small orifice would suffice, and he did not think more than three quarters of an inch was ever necessary. The author then gave short histories of three cases.

Dr. J. M. Barton could speak most favorably of inguinal colotomy. It gave us an opportunity of determining what portion of the bowel was involved and making an opening well above the disease. It also permitted us to explore the glands in the interior if removal of the rectum was contemplated. In regard to opening the bowel, he had preferred to permit it to remain at least four or five hours before opening it; by that time the peritoneal surfaces were adherent. It had been recommended to leave the bowel twenty-four hours and then open it with the Paquelin cautery. This seemed unnecessary. He usually employed scissors, and controlled any bleeding that might occur with hæmostats. He had had no difficulty from prolapse.

Dr. John B. Deaver said it had fallen to his lot to do several colotomies, but only one or two inguinal. His reason for preferring the lumbar method was chiefly that it was an extraperitoneal operation. Another reason was that, if the disease extended, it would take longer to reach the opening in the loin than one in the abdominal wall in front. He was free to confess that he had been largely influenced by the views of Mr. Bryant. The lumbar operation was not by any means difficult. He thought that it was quite as simple as the abdominal operation, and, where there was distention, simpler. In the anterior operation distention increased the difficulty. The anterior wound could probably be looked after better than one in the loin, but it was more difficult to keep a pad in position in the former case.

Dr. T. S. K. Morton said that not many days before he had done an iliac or inguinal colotomy, and a most curious feature of the case had been an apparent transposition of the colon to the right side. On making the incision in the left side the colon had presented. He had had considerable difficulty in locating the descending colon. He had finally traced it to the right inguinal region. The lumbar operation, he thought, would not have been feasible in that case.

There was one point which he thought had not been sufficiently emphasized, and that was the importance of making a spur. This could not be done by suturing the side of the bowel to the abdominal opening. If little pieces of fæces passed the opening and reached the diseased surface, they caused a great deal of pain. He had seen nothing equal to a bar of glass or other material passed through the mesocolon for securing an adequate spur. When the bowel was cut transversely upon this support there were two openings presenting, one above the other, and it was impossible for fæces to pass across. So far as the control of the anterior opening was concerned, in the cases that he had seen it had been almost perfect.

With regard to prolapse, Mr. Allingham had proposed dragging into the wound as much colon as possible and removing the redundant portion: he maintained that this would prevent subsequent prolapse. This method had been condemned by others, and it had been found sufficient to make the upper part of the colon taut before fixing it. The size of the opening, he thought, should be of the entire diameter of the bowel. This gave some sphincter-like action to the end. It had occurred to him that we might employ here Gersung's operation for incontinence of fæces from the anus—namely, rotating the bowel a full circle before suturing it. It had been shown that where incontinence was present an efficient sphincter could be made in this way and one that would control liquid fæces.

Dr. John B. Roberts said that a limited experience with both operations led him to strongly favor the inguinal method. He felt with Dr. Morton, that the important thing was to obtain the spur. He did not see how that could be easily done without using some form of support and bringing the mesentery out of the wound. He thought it a most important feature. He preferred, where it could be done, to wait a few days for adhesions to take place. In opening the bowel he was inclined to prefer cutting entirely across.

Dr. PACKARD said with regard to the making of a spur, it had never been necessary in any of his own cases, and he thought it could only exceptionally be of advantage. If the opening made was sufficient, the fæces would escape easily through it, and the lower part of the bowel had been, in his cases, kept quite free from irritation by them. Of course, if a spur was to be made, the bowel must be drawn clear out.

As stated in the report of his cases, there had, in the third especially, been still some tendency to prolapse in spite of the drawing down of the bowel, and he should be glad to know of some other way of preventing it.

He was aware that Allingham advised the complete section of the bowel, but it seemed to him to add to the gravity of the operation without adequate advantage. A properly adjusted pad ought to keep its place without trouble.

The Effects of Erysipelas on Epithelial Cancer,—Dr. James Collins related a case in which, about eighteen months before, a man had called his attention to an ulcer nearly opposite the ear, on his right cheek. This ulcer was an inch and a half in its longest diameter, an inch in the shorter, presenting an oval with irregular edges. The discharge was slightly purulent, tinged with blood. The granulations were soft and bled on the slightest touch.

The man stated that twenty years before there had appeared at this point a small elevation, which had frequently formed a scab, which every ten or twelve days would fall off and then reform; it had given but little trouble and received but little treatment.

Nineteen years before he had been treated for a time with ointments and lotions, and some medicine had been administered without special benefit. He was then assured that this was skin cancer and incurable. This ulcer had gradually increased in size and depth. Some benefit had been derived from a lotion of zinc sulphate and salt, dissolved in water to make a mild astringent solution. The ulceration, however, had continued, giving inconsiderable pain, but much annoyance by its presence. The good man had quietly accepted the situation, and sought only palliation and relief from pain.

About November 12th he had suffered from an attack of erysipelas of the face. This ran no unusual course, spreading rapidly from the tip of the nose over the scalp to the nape of the neck. The efflorescence had been followed by desquamation. The external dressing was of ichthyol and lanolin, which had seemed to give relief and comfort.

As the erysipelas had faded out, granulations of a more normal character had developed, and in about two weeks the ulcer had entirely healed. The cicatrix on March 1st was slightly indurated, but smooth and firm, and presented the appearance of normal cicatricial tissue.

This case was reported without special comment. Dr. Coley, of New York, had written on this subject with considerable interest.

The writer was well aware that a single case from the practice of a surgeon was but of little value, isolated and alone, but hoped that others might add their experience and observation.

Dr. John B. Deaver said that Dr. Collins's report was of great interest. He now had a patient with osteosarcoma to whom he had given the erysipelas toxine, but it seemed to have no effect. Dr. Bull and Dr. Coley told him that it had proved

of no value in such cases. Further, they had practically discarded it in carcinoma.

Dr. H. R. Wharton said he had had no personal experience in the treatment of carcinoma or sarcoma with the virus of erysipelas. He had under observation a patient with inoperable carcinoma of the face who had consulted Dr. Bull, and he had advised that this treatment should not be tried. The results in carcinoma had not proved satisfactory, he understood from Dr. Bull, but thought he considered the prospect more promising in cases of sarroma.

Dr. Orville Horwitz said he had had three cases—two of sarcoma and one of carcinoma—treated by the hypodermic injection of the crysipelas toxine. In the case of carcinoma and in one case of sarcoma there had been no benefit. In the third case, the mass involving the side of the neck had become much softened, and it looked as though some improvement had taken place.

Dr. Peneose said his experience was limited to one case of inoperable carcinoma of the right superior maxilla which had existed some two years. Three or four operations had been done, but the disease had finally got beyond bounds. Last spring this woman had accidentally acquired erysipelas, and had had one of the worst attacks that he had seen, but it had had no effect on the neoplasm. The progress of the growth had been the same as before. The beneficial effect of this antitoxine was limited almost exclusively to the softer forms of sarcoma—to sarcoma of the soft parts.

Vaginal Hysterectomy.—Dr. John B. Deaver, in a paper on this subject, said he was convinced that hysterectomy should not be relegated solely to those who worked in the field of gynæcology, but that it belonged as well to the general surgeon. In support of what he had said he might be privileged to ask the question, Was not the surgeon who met with all forms of surgical complications better prepared to meet such than the limited specialist who had not had a general surgical training? Furthermore, if the general surgeon in the pursuance of his work had kept up his anatomical work, and opportunity had been given him to observe in hospital as well as in private practice the class of cases he proposed to discuss this evening, he thought it would be agreed that a paper on this subject by a general surgeon would not be considered out of place.

The symptoms of carcinoma of the cervix might be so slight at first that the patient would pay no attention to them, but would attribute the sensations experienced to the change of life, at which time cancer in this locality usually made its appearance. From the insidious character of the invasion, considerable involvement would generally have taken place ere the case came to the notice of the attending physician or surgeon. A slight hæmorrhage was noticed, following exertion or coitus, and occurring between the regular menstrual periods. This usually did not alarm the patient until it became a frequent occurrence. It had been compared to the hæmoptysis of early pulmonary consumption, but was unlike it from the fact that there was no active destructive change going on as yet. A leucorrheal discharge was present, although without the characteristic cancerous odor. In the first stage the general or constitutional manifestations of cancer did not present themselves. Pain, however, was one of the earlier symptoms. There might be disturbance either of the digestive or of the flervous system, or of both.

Following this preliminary stage there was usually a period of latency prior to the second stage, when all the symptoms were present to a marked degree. The hamorrhages were more frequent and at times were profuse. There was also present a sero-purulent, irritating discharge, with a penetrating, foul odor, and by contact with the internal and external geni

talia it gave rise to irritation and pruritus, which often caused as mach distress as the primary disease. The pain was severe and racheting in character, and was feit most in the lardsar region. The uterus users the fixed or moval ic; as the disease progressed the means became fixed by extension of the means to the second the steams. Examination with the speculum was often unsatisfactory, unless ulceration or granulation tissue was present; the finger more readily detected the changed character of the tissue, recognizing neoplasm from its consistence.

The general condition of the patient during the second stage underwent a marked change. The digestion was very much impaired; ancrexia, constipation, etc., were present, and gave rise to systemic malnutrition. As a result of this general disturbance, what was known as the "cachectic stage" made its appearance. The skin was dry and rough, and its color was changed to a muddy yellowish-brown tint.

The conditions from which cancerous disease of the cervix was to be distinguished were the following: Lacerated cervix with cervical catarrh, erosion of the cervix, specific ulceration, mucous patches, papillary growths, elytritis, myoma, and sarcoma.

The diagnosis of the cervical carcinoma was in the main easy, as the cases were usually seen after positive ulcerative and other gross changes had taken place. Where there was simply thickening of the mucous lining of the cervix, with infiltration of the walls, and particularly where the cervix had been torn, it became somewhat difficult to distinguish roog a long-standing casof cervical catarrh. When, in addition to the above-mentioned conditions, the cervix presented a nodular appearance from occlusion of the cervical glands, the difficulty was increased. This latter condition, however, should not be mistaken for carcinoma, as the nodules were characteristic of malignant infiltration.

If ulceration was present, and the ulcers presented a punched-out, ragged appearance, bleeding freely from the slightest touch, suspicion should be aroused. On the other hand, ulceration consequent upon erosion of the cervical mucous membrane was regular in outline and the surface of the ulcer smooth.

Specific ulceration of the cervix, chancrous and chancroidal, was tarely seen, and bore little or no resemblance to carcinoma, and in connection with the history of the case, age of the patient, etc., should not cloud the diagnosis.

Mucous patches and papillary growths were more likely to be confounded with the disease than the two preceding conditions; these were, however, distinguishable in that they were more numerous and more widely distributed.

The discharge which accompanied elytritis in no way resembled that resulting from carcinoma.

Myoma of the cervix might be confounded with a single carcinomatous nodule, but differed from the latter in the absence of infiltration, inflammation, and adhesion of the overlying the constant of the conformation.

In incipient carcinoma of the mucous lining of the uterus, before the body had become involved, the only symptoms were to panied by odor, and the general appearance of anemia with debility and digestive disturbances. Pain might or might not be a with the failure to respond to well-directed treatment, and the absence of disease of the uterine annexa should warrant dilatation.

sero-sanious discharge with the characteristic odor, associated with the ment lab related and characteristic of the limits.

would warrant curetting and a microscopical examination of the particles of tissue removed. This might be done without anæsthesia.

Sarcoma of the uterus was capable of giving rise to symptoms similar in many respects to those of carcinoma. While it was not always possible to distinguish between these affections, they each had symptoms peculiar to themselves.

The symptoms in favor of sarcoma were the presence of a rapidly growing tumor of the uterus appearing rather earlier in life than carcinoma; hæmorrhage, which was more or less constant, and severe pain.

The diagnosis of sarcoma could often be established by a digital examination, when the cervix would be found less patulous than in carcinoma, the tumor presenting the form of a polypoid growth. It might be necessary to dilate the cervix to explore the interior of the uterus, when, if a mass was found, a portion of it might be removed and examined.

As to the probable outcome of a vaginal hysterectomy for carcinoma, it was too early in the history of the operation to draw definite conclusions, but the results thus far had proved that especially early and even later operations had prolonged life. There was no doubt that removal of the uterus for carcinoma offered a longer immunity from return than operations for the same disease in other parts of the body, if done early.

Fatal attacks of uremia might follow, though it was rare to ave eclamptic convulsions.

By extension of the disease the bladder and rectum became involved, and as a result cystitis or vesico-vaginal or rectovaginal fistula might arise to add to the already deplorable condition of the patient. Peritonitis from extrusion would cause a speedy termination of the case, as would an embolus.

Pregnancy was a dangerous complication, as septicæmia or fatal hæmorrhage was likely to ensue if the case was permitted to go to the full term.

The relations of the ureters were of so much importance in this operation that the writer had thought it worth while to describe their course. They extended from the termination of the pelvis of the kidney to the bladder, passing through the laminæ of the subperitoneal connective tissue. Their average length was about twelve inches. At their commencement they lay about three inches apart, but on nearing the base of the bladder they ran forward and inward and pierced its wall, and at their termination were separated by a distance of about an inch and a quarter.

We might describe them as consisting of three portionsnamely, abdominal, pelvic, and vesical. The abdominal portion was in relation posteriorly with the psoas muscle and its fascia, the genito-crural nerve, and the common iliac artery. Anteriorly they were covered by the peritoneum, and on the right side lay partly under the caput coli and ascending colon, and under the descending colon and sigmoid flexure on the left. About the middle of their course they were joined by the ovarian vessels, which crossed them to descend into the pelvis along their outer border. At the brim of the pelvis the right ureter lay just behind the peritoneum, where it could be seen with the ovarian vessels. On the left side, the relations of the ureter to the sigmoid flexure depended entirely upon the length of the meso-sigmoid. Thus in one case the ureter might lie behind the sigmoid vessels, and in another directly behind the inover the common iliac artery above its bifurcation, dropping into the pelvis at this point.

The pelvic portion ran in front of the sacro-iliac synchondrosis, then upon the obturator internus muscle and its fascia, finally leaving the pelvic wall to join the bladder. It lay at first usually to the inner side of the internal iliac artery, subsequently to the outer side, and was again crossed by the ovarian veins and artery, which left it at an acute angle. It then descended in the lower cellular tissue to the floor of the pelvis in a forward direction, passing directly under the uterine artery, and through the uterine plexus of veins and beneath the base of the broad ligament. Finally it crossed the upper third of the vagina to reach the vesico-vaginal interspace, and pierced the bladder opposite the middle of the vagina.

The vesical portion, about half an inch in length, ran obliquely downward and inward through the coats of the bladder to open on the mucous surface at a distance of about an inch to an inch and a quarter from its fellow, and the same distance from the internal urinary meatus.

The uterine artery left the lateral pelvic wall at a point just above the isolial spine, reached the vaginal wall at the level of the os externum, and then ran upward along the side of the uterus to reach the fundus.

Much depended upon the preparation of the patient for operation. The most careful antisepsis of the vulva and vagina should be carried out. It was the practice of some surgeons to have the hair covering the soft parts removed; the writer did not believe this necessary if this region was thoroughly scrubbed twice a day with some good detersive soap for two or three days prior to the operation. The vagina should be cleansed with soft soap, and then both the external genitals and the vagina irrigated with a 1-to-60 carbolic acid solution containing an amount of bichloride of mercury to make it equivalent to 1 to 4,000. The bowels should be carefully regulated, and a mild laxative administered for a few days before the operation to thoroughly clean out the lower end of the alimentary canal. If there were present granulations covering the cervix or occupying the uterine canal, or should the cervix be eroded and accompanied by a feetid discharge, it would be wise at first to curette away the granulation tissue exciting the discharge, and subject the vagina to bichloride irrigations twice or thrice daily, the frequency depending on the character of the discharge.

In the operation of vaginal hysterectomy one of three methods was practiced—the clamp, the ligature, and that by enucleation (Langenback's). There was no doubt that the method by enucleation was the ideal one, and the one that should be adopted when the case was suitable for it.

The enucleation method consisted, first, in liberating the cervix by carrying two elliptical incisions through the vaginal wall in front of and behind the cervix, or by a circular incision carried around the cervix, the dissection being made close to the cervix. This should be the rule whatever method was employed. In the removal of neck tumors in the immediate neighborhood of large vessels, or, in fact, any tumor occupying an important vascular locality, the surgeon followed the practice of dissecting close to the tumor. The second step in the enucleation method was that of making a subperitoneal dissection of the uterus. He thought this should be the operation of choice, in the early cases at least.

Between the clamp and the ligature method there was in his mind no doubt of the superiority of the latter. He granted there were a few cases where the clamp method was probably the better operation, but those constituted the exception. The ligature method of vaginal hysterectomy was as much superior to the clamp as was the dropping of the stump in the supravaginal, having tied off the uterine appendages and ligated the uterine arteries, over that of the serre-næud. The ligature was surgical, while the clamp compared to it was unsurgical.

In the selection of any operation, that which would leave the patient the most comfortable, not, of course, exposing her to a single additional risk, should, in his judgment, be the one of choice. He was frequently confronted with the argument, "Why, the clamp method could be done in fifteen minutes and less." In answer to which his reply was, The ligature method could be done in thirty to forty minutes. The question of a few moments longer in doing the operation was of no import, as, if the case was suitable for a hysterectomy, there would be no shock. The loss of blood in the ligature method was no greater than that in the clamp, if done properly, and the security against secondary bleeding was much greater. The ligature method was one that could be made a strictly aseptic one, and maintained so throughout, while in the case of the clamp there was always some suppuration following, thus exposing the peritonæum to infection from without.

The question might arise, Why not close the wound in the vault of the vagina? The wound would close itself. He had observed, and demonstrated after the removal of the uterus, the almost perfect apposition of the cut surfaces; therefore, he had never been able to see the necessity of introducing sutures. If bleeding followed reaction from the anæsthetic, and the wound in the vagina had been closed by sutures, it might be the cause of a subsequent abseess, while in allowing the edges of the wound to appose naturally, and introducing a little packing of iodoform gauze into the vagina, not carrying it into the pelvic cavity, the blood found its way into the vagina and was taken up by the gauze. By the time reactionary or consecutive bleeding, if we saw fit to call it such, would occur, the wound in the vagina would not yet have been sealed off; therefore it found its way out of the pelvis.

In either the ligature or the clamp method, when the cervix was entirely destroyed, thus making it impossible to grasp it with a volsella or pressure forceps to pull the uterus down, his practice was to introduce a tenaculum into the uterus, by which he was able to make slight traction, and thus steady the organ; this allowed him to free the vaginal walls and expose the supravaginal portion of the cervix, which he grasped with the volsella, and thus commanded the uterus through the remaining steps of the operation.

The bowels and bladder having been emptied, the patient was anæsthetized and placed in the lithotomy posture, with her limbs held by assistants. A Sims's speculum was introduced and the cervix uteri exposed. The cervix was then grasped either by a volsella or a pressure forceps, the latter being less likely to slip or tear out. Traction was made upon the uterus, drawing it downward and forward to expose its under surface. An incision was carried across the exposed surface to the situation of the internal os, or as far away from the eroded tissue as possible, and with the fingers the posterior wall of the vagina and the areolar tissue were freed from the uterus down to the peritoneum. The forceps holding the uterus was then carried downward, and the incision continued to make it encircle the organ. The structures in advance of the uterus were dissected away in the manner before described, great care being observed to keep close to the body to prevent injury to the bladder; having reached the vesico-uterine folds of the peritoneum, the vagina was thoroughly irrigated. The rectouterine and vesico-uterine folds of the peritoneum were now broken through, and, if the operator so desired, a small piece of gauze or sponge was introduced to prevent prolapse of the intestine; this he did not believe, however, to be essential. The female biade of the clamp was then introduced along the palmar surface of the finger, which acted as a director. The blade of the clamp was made to hug the lower surface of the broad ligament, and the end of the blade was made to pass beyond its upper limit. The handle was depressed to make the end appear above the upper surface of the ligament, the other blade introduced, and the clamp locked. The opposite side having been treated in the same manner, the attachments were severed and

the uterus was removed. Should difficulty be experienced in applying the second clamp, the attachment of the side already clamped might be severed, and the body of the uterus loosened and extracted, when the clamp could be easily applied.

A piece of sponge or gauze was introduced, and the vagina was irrigated; gauze was loosely packed around the clamps to prevent ulceration of the soft parts from pressure, and a light packing placed in the vagina to act as a capillary drain.

The clamps might be removed at the end of the second or third day. In removal of the uterus by the ligature method, the early steps were the same as in the clamp operation. Having freed the uterus from all its surrounding tissues, except the broad ligaments and the peritonæum covering the fundus, the vagina was thoroughly irrigated. The broad ligaments were now to be ligated. An aneurysm needle, curved on the flat and set at right angles to the handle, was threaded with a silk ligature and passed through the base of the right broad ligament a short distance from the cervix; this secured the uterine artery. Successive ligatures were then applied until the entire ligament was tied off. As each ligature was tied the included portion was cut free from the uterus. Having ligated and secured the right ligament, the left was treated in the same manner.

If there was an elongated body, as was often found in uterine carcinoma, great difficulty might be experienced in ligating the entire ligament upon one side without tying off and removing a portion of the ligament of the opposite side. By adopting this course the organ could be pulled down and the remaining ligatures easily applied. As the ligatures were being tied down, the traction of the uterus should be relaxed. The uterus having been freed from its ligamentous attachments, the peritonœum was broken through and the organ removed.

After the uterus had been removed it was the custom of some surgeons to close the opening in the vagina. He did not practice this. The cut surfaces approximated themselves, and further favored drainage, if we simply packed the vagina and did not stitch.

The author then related four cases illustrating his views.

Dr. C. B. Penrose said that in the diagnosis of doubtful cases Dr. Deaver had spoken of dilatation and curetting. He had found this unsatisfactory in most cases. We might be obliged to rely on it in cancer of the fundus, but in suspected cancer of the cervix he thought that it was better to cut out a wedge-shaped piece. He had done this in fifteen or twenty instances, and in many of them had recognized cancer in its early stages. With regard to the method of operation, he preferred removal through an abdominal incision in all cases, if necessary making a preliminary incision in the anterior and posterior vaginal fornices in order to be sure that all infiltrated tissue in the vagina was removed. By this method one could more readily deal with any complications that might arise.

Dr. Deaver said that he quite agreed with Dr. Penrose that the removal of a portion of the cervix for diagnostic purposes was more reliable than curettement; but this was not applicable in all cases. He should like to hear from Dr. Penrose what was the status of removal of the tubes and ovaries in these cases. He always attempted to remove them because he saw no advantage in leaving them. He should like to know if this lessend the liability to recurrence. The ovaries, however, did not hold the same relation to the uterus that the lymphatic glands did to other structures.

Dr. Penrose said he thought that the chief reason that it was desirable to remove the tubes was that in twenty-five to thirty per cent. there was extensive disease of the tubes, not necessarily malignant, however. The ovaries, he thought, in young women might be left in order to preserve the ovarian influence.

Abdominal Hysterectomy in which the Ureter had been Resected and Implanted into the Bladder.—Dr. Charles B. Penrose reported this case because, he said, the immediate implantation into the bladder of a ureter, which had been divided during a coliotomy, was a rare proceeding.

The patient was a white woman, forty years old, who had had a scirrhous cancer of the cervix uteri. The growth had extended as high as the internal os, and infiltrated the left broad ligament in a dense hard mass to a distance of about an inch from the cervix. There had been no involvement of the vagina. There had been no symptoms of obstruction of the preter.

Cœliotomy had been performed at the Gynecean Hospital in July, 1893. It had been found that the left ureter passed directly through the hard mass in the left broad ligament; and in order to remove completely all diseased tissue it had been necessary to excise about an inch of the ureter—the portion involved in the broad ligament.

After the uterus had been cut away at the vaginal junction, the distal end of the ureter had been ligated with silk, the vagina had been closed, the peritonæum had been sutured over the seat of operation as much as possible, and the proximal portion of the ureter had then been implanted into the body of the bladder. The operation was similar to and had been derived from that used by Dr. Van Hook for uniting a ureter after complete transverse division, by lateral implantation of the proximal into the distal portion (Jour. of the Am. Med. Assoc., March 4, 1893). An incision had been made antero-posteriorly in the body of the bladder somewhat less than half an inch in length. A needle armed with fine silk had been passed through the bladder wall from without in, at a point about a third of an inch from the edge of the incision on the right, and brought out through the incision. It had then been passed through the right wall of the ureter close to the extremity, carried back through the incision in the bladder, and passed through the bladder wall from within out, close to its point of entrance. A similar suture had been passed on the left side of the incision in the bladder and through the left side of the wall of the divided ureter. Traction on these sutures had dragged the ureter into the bladder, and when tied they had held it in this position.

The loose peritonsum, which had formed a partial investment to the ureter, had been drawn down and sutured to the peritonsum of the bladder by a continuous silk suture around the line of union of ureter with bladder. The abdomen had been closed without drain. A soft rubber catheter had been introduced through the urethra and was retained for three days. The patient had made an unusually easy recovery.

There had been no symptoms of bladder or renal disturbance. The quantity of urine passed was as follows: Ten ounces in the first twenty-four hours, twenty-six ounces in the second twenty-four hours, twenty-two ounces in the third twenty-four and thirty-eight ounces in the fourth twenty-four hours.

She had left the hospital twenty days after the operation. Her physician had written him in December that she was perfectly well and doing her own housework. He had written again in February—over six months after the operation—that she had been suffering with pain in the right iliac region—perhaps a recurrence of the disease.

She had at no time presented any symptoms whatever of disease of the urinary organs.

Text-books on surgery advised that, in case the ureter was torn or cut across during the removal of an abdominal tumor, the renal end must be brought out through an opening made for this purpose in the loin. And in some instances nephrectomy had been performed for the reliet of such an accident. The clinical and experimental researches of Dr. Van Hook, of Chicago (paper read at the forty-fourth annual meeting of the American Medical Association, June, 1893), a recently reported case of Dr. H. A. Kelly's in which a divided ureter had been immediately united by lateral implantation of the proximal into the distal portion, and the case just reported went to show that the advice of surgical text-books should be modified, and that, if the patient was able to endure a slightly prolonged operation, and the anatomical conditions were suitable, it was better to immediately implant the proximal portion of the ureter into the distal portion or into the bladder.

Conditions Justifying Removal of the Testicle in Radical Operations for Inguinal Hernia; with a Report of Three Successful Cases.—Dr. Thomas S. K. Morton read a paper on this subject, in which he said that he desired emphatically to impress the fact that he was not there to advocate the indiscriminate sacrifice of an organ usually so highly prized as the testicle, but simply to point out certain of the conditions which would appear to him to justify the procedure and to relate three cases in which he had considered it best to resort to it. These cases represented the total number in which he had deemed it prudent to add ablation of the gland to formal procedures for the radical cure of inguinal hernia, for instances were rare in which this course might be considered justifiable, and must become constantly more and more so as radical procedures become perfected.

With the operations proposed by Bassini, Postempski, and Halsted, with their modifications, where the cord was displaced entirely from the inguinal canal, and, in the latter, even removed from the internal ring to an entirely new opening made for the purpose in the muscular structures of the abdominal wall; with these operations, he said, the presence of the cord had almost ceased to be a hindrance to seemingly ideal radical cure. Hence any temptation to sacrifice the testicle vanished and the conditions necessitating or permitting such removal became correspondingly more circumscribed.

Removal of the testicle in operations for inguinal hernia would, therefore, in his estimation, be practically limited to the following conditions:

- 1. Certain cases of undescended testicle. Here, if the testicle had entered the canal and was degenerated or otherwise diseased, or could not be separated from the sac without endangering its vitality, or where it was manifestly functionless, it might be removed without reluctance. But if it was normal or almost normal in all respects save position, it would be best, if possible, to displace the cord from the canal by one of the modern methods and attempt to bring the organ into the scrotum and there fix it by sutures; or it might be pushed within the abdominal cavity through the internal ring, and there permitted to remain after close suture of the ring.
- In some rare cases of congenital hernia. Removal here must be very exceptionally called for with so many modern operative resources at hand.
- 3. In certain cases of chronic or acute disease of the testicle or cord complicating hernia demanding removal of the organ upon its own account.
- 4. In rare cases in which severe traumatism had occurred to testicle or cord during or before operation. Accidental division of some or all of the vessels of the cord would not necessarily demand excision of the testicle unless other severe complications were present. Wounding or section of the vas deferens likewise might be consistent with retention of the organ. But where the gland had been stripped entirely from all other connections, such injury to its vascular supply would produce so much danger of necrosis that ablation would become imperative.

- 5. In certain cases where sloughing of the sac or interrupted circulation of the cord or testicle had involved these latter structures in a suppurative or sloughing process.
- Perhaps occasionally in the very aged, to simplify or shorten the operation, or for some of the before-mentioned conditions of less degree than would justify the procedure in a younger individual.

There were no conditions of course, except senility, that would excuse the removal of a testicle under circumstances where it was the sole reproductive gland possessed by the individual; even rarer would be the conditions justifying removal of both testicles in double herniæ.

Surgeons must be exceedingly cautious not to interfere with so highly valued a part without either a very clear understanding with the patient before witnesses (and preferably in writing) preliminary to the operation, or else the certainty that the conditions for which the organ was removed would be convincing to others of the necessity for such removal. It was obviously important also for the operator to carefully preserve the specimens for his protection in case of dispute.

One word more of caution. It was not the easiest matter to tie off the testicular cord in such a manner as to leave it absolutely secure against recurring or secondary hæmorrhage after its return to the abdominal cavity; and bleeding from it originated a peculiarly dangerous form of shock quite independent of the amount of blood lost, which often was speedily fatal. Moreover, the bleeding would not be likely to cease spontaneously in the warm and moist peritoneal cavity to which the ligated stump had been returned, and an operation to secure it more firmly (if a diagnosis was made in time) would be a very formidable complication. Hence, excessive care must be exercised in its primary ligation. It should be transfixed and tied off in at least two portions. Silk was the only fit material for this purpose. A good button of tissue should be left above the ligatures, and, to be doubly sure, any apparent vessel ends should be separately ligated upon the end of the stump before it was returned to the cavity. Searing the stump with a cautery below the main ligatures would be equally efficient as the separate ligatures to the vessel ends. If the cord was very large or ædematous it should be ligated in even smaller por-

Three cases were related illustrating the author's views.

Dr. Joseph H. Packard said he wished simply to refer to one practical point in the treatment of these cases, and that was the use of swimming drawers to hold the dressings in place. It was difficult to apply a bandage that would keep its place perfectly, and he had found this method answer an exceedingly good purpose after various operations in the pelvic region.

Dr. John B. Deaver said that in this connection he should like to state that Banini had reported a year ago five hundred and sixty operations, with fifteen relapses and no deaths. There were only two points which he wished to mention. One was the kangaroo tendon now used by most surgeons. The second was enveloping the entire limb in a plaster-of-Paris bandage. A great deal of the perfect asepsis was due to the latter.

## Miscellany.

Resection of the Urethra.—In the Lyon médical for March 25th Dr. Étienne Rollet, adjunct professor of the Lyons Faculty of Medicine, relates a case of resection of the whole circumference of a strictured urethra to the extent of six centimetres

(about two inches) of its length, in a case complicated with fistulæ and extensive indurations. The author remarks that at present there is not a satisfactory feeling of certainty in regard to the results of urethral resection for the cure of certain strictures due to gonorrhea, and that this is in consequence of the paucity of the operations that have been performed. Even partial resection, he says, is rejected by the surgeons, and he quotes from a recent text-book on strictures of the urethra by Hamonic the following expressions in condemnation of that operation: "In place of the fibroid tissue of the stricture there is substituted a band of cicatricial tissue which will not fail, even under the most favorable conditions, to produce a more serious stricture than that which existed at the start. Resection must lead to shortening of the canal." At first sight, the author goes on to say, total resection-i. e., removal of the entire circumference of the diseased portion of the canal-seems destined to afford results far inferior to those of partial resection, for, say the classical writers, in the latter we preserve the floor of the urethra, which is indispensable for the reconstruction of the canal. However, he continues, theoretical arguments against urethral resection, even total resection, are not in consonance with the results, which are quite remarkable. There is a class of serious blennorrhagic strictures accompanied by hard and voluminous callous masses and multiple fistulæ. These morbid products and canals may be extirpated as well as the entire strictured portion of the urethra. After such an operation the canal may be resected in any one of three different ways: 1. A permanent catheter having been introduced, the tissues may be left to granulate around it; in this way restoration of the canal and of the perineum is obtained by second intention. By this measure the cure is exasperatingly slow, and the remote results are generally bad and sometimes call for complementary plastic operations. 2. Daniel Mollière devised a method by which, after urethrectomy, the urethra was restored by sewing its two ends together. This method has given very good results, but it must always be remembered that the urethral suture is very delicate and generally gives way. 3. The surgeon must content himself with creating an artificial canal around the catheter by suturing the soft parts adjacent to the urethra. Hitherto those who have practiced this method have preserved a small portion of the lumen of the urethra, but in a case related by the author this precaution was omitted. The case was that of an artisan, thirty-nine years old, who was admitted into the author's hospital service on September 9, 1893, on account of pain and difficulty in urination, together with perineal fistulæ through which there flowed a mixture of pus and urine. He showed signs of syphilis, but at the time of his admission he had no progressive lesions of the skin; there was nothing abnormal on any of the mucous surfaces, and there was no lesion of the osseous system. Nothing abnormal was noted about the external genitals except that the meatus was a little contracted. In the perinæum there was found a mass as large as one's fist, elongated from before backward and in breadth almost filling the space between the two ischia. This mass, situated in the median line, developed equally to the right and to the left, was covered with skin of an almost uniform deep red, violaceous color. On palpation, this mass was indolent, nodular, but slightly movable, of unequal consistence, but very hard in certain places. At several localities on the perineal surface thus deformed by this mass of irregular induration there were observed a certain number of little funnelshaped depressions more or less deepened in color at their openings. From some of these a small amount of liquid more or less purulent could be seen to exude. Moreover, on the left half of this perineal mass, a short distance from the median line and about two fingerbreadths in front of the anus, there

was to be seen an inflamed surface, more tense and redder than the neighboring skin and presenting a little narrow opening by which there escaped urine, easily recognized by its odor and turbid serosity. This discharge had accumulated during the preceding night-that is to say, during a few hours. A probe introduced into this opening was arrested in the midst of hard tissues at a depth of three centimetres. The patient said that he urinated sometimes by the catheter, sometimes by the fistulæ. Urination by the urethra had generally been comparatively easy except for the last few days; urine escaped drop by drop from the fistulæ and kept the patient constantly wet. A No. 15 conical flexible olivary bougie introduced in the urethra was arrested at nine centimetres from the meatus. Similar bougies, Nos. 12, 9, and 6, well oiled, proved equally incapable of complete introduction. On the 10th of October the author saw the patient and decided to practice urethrectomy with complete ablation of the indurated mass. On the 18th, anæsthesia having been induced with ether, preceded by an injection of atropine and morphine, under the ordinary antiseptic precautions, it was found impossible to make the grooved sound enter the urethra more than to the distance of nine centimetres. An incision was made in the median line, extending from the scrotum to a point two centimetres in front of the anus, through a hard mass which creaked under the knife. It was only when a depth of four centimetres was reached that the beak of the sound was felt. On causing the latter to protrude a little, the anterior part of the bulbo perineal portion of the urethra, coinciding with the front of the stricture, was opened. This metallic sound was withdrawn and replaced by a No. 16 flexible bougie, which was passed out through the opening, bent back upon itself, and tied by its two ends in front of the meatus. By this loop of bougie the parts situated in front of the stricture were kept elevated and the lips of the perineal wound were held apart laterally by means of wires; then the excision of the indurated tissues surrounding the urethra, amid which the urethra was lost, was proceeded with. This part of the operation took about fifteen minutes. The indurated mass thus removed, partly with a sharp curette and partly with curved scissors, was of about the size of a large orange. Little purulent collections were found at two or three points. These masses having been removed, there was left a broad and deep breach of continuity, bleeding but little, measuring about eight centimetres from before backward and five centimetres across. Therefore between the anterior and posterior portion of the severed urethra there was a gap of at least six centimetres. M. Rollet then endeavored to find the vesical portion of the urethra by means of a channeled sound. Toward the lower angle of the wound he presently discovered it and introduced into it Tripier's guttered dilator, by which there escaped somewhat turbid urine. Then the bougie that had been tied into the penile portion of the urethra was withdrawn and replaced by a No. 21 Nélaton's catheter, previously disinfected and coated with an oily solution of salol, which, after having emerged from the anterior portion of the urethra, traversed the perineal region for the space of six centimetres and was made to enter the deep portion of the urethra with the guidance of the guttered dilator, which was withdrawn simultaneously with the insertion of the catheter into the bladder. Urine immediately escaped at the mouth of the sound. After the bladder had been emptied it was washed out with a 1-to-1,000 solution of nitrate of silver in tepid water. The catheter was fixed in place by means of a strong wire passed through its walls and also through the thickness of the two lips of the perineal wound. Then the artificial reconstruction of the urethra was proceeded with. To accomplish this, M. Rollet gathered the perineal tissues about the fixed catheter and united them upon it by means

of two tiers of silk sutures. Finally a superficial tier of cutaneous metallic sutures was inserted. The wound was dressed with iodoform and cotton, the legs were tied together, and the catheter was connected with a siphon tube leading outside of the bed. The immediate results of the operation were excellent—there was neither rise of temperature, escape of urine by the wound, nor suppuration.

On the 23d of November it was noted that the perineal wound had long been completely and solidly united. The wire which held the catheter in place was cut; after having been thirty-six days in place its surface presented only a very slight layer of incrustation. The bladder was washed out without the aid of a catheter. The patient could pass water in a full stream. He was ordered salol and sulphur baths. The further history of the case is unimportant. The author remarks that it is unparalleled, so far as he knows, as regards the length of the urethra resected, the size of the indurated masses removed, the immediate union which took place, and the excellent results observed as late as five months after the operation. The author expresses himself as convinced that the reconstructed portion of the urethra became covered with epithelium.

The Copious Drinking of Water as a Method of Treating Typhoid Fever.-In the March number of the Revue de médecine Dr. Hector Maillart, of Geneva, concludes an article on this subject. As a result of his study of it, he feels convinced that the treatment of typhoid fever by copious drinks may be recognized as a definite method. In order that the treatment may be efficacious, the patient should drink at least from five to six quarts of water daily during the whole febrile period. There is no contraindication to this treatment; feebleness of the heart, far from contraindicating the drinks, may become a special indication for them. The results are a progressive lowering of the fever, disappearance of the dryness of the tongue and mouth, and pronounced sedation of all the alarming nervous, circulatory, and renal phenomena. These results are due to the oxidation of toxines and refuse material, which are rendered soluble and eliminated. The oxidation is shown by the formation of great quantities of urea, and the elimination takes place by the skin and kidneys in the form of profuse sweating and abundant diuresis. This diuresis re-establishes the integrity of the renal filter, and that results in the rapid disappearance of albuminuria. This method of treatment has no notable influence on the course or the duration of the disease. No unpleasant consequences have been observed to result from the treatment, either during the fever, during convalescence, or after recovery. The treatment, which is very acceptable to the patient, is easily carried out, even in cases in which the nervous disturbances are very decided.

A Fatal Case of Cocaine Poisoning,—At a recent meeting of the Paris Société de chirurgie, reported in the Journal des praticiens for March 24th, M. Reclus read an account of a case which had been sent to him by a physician in the country. It was that of an old man who had died speedily after an injection of cocaine into the urethra. He was seventy-two years old, affected with heart disease and arterio-sclerosis, and subject to attacks of angina pectoris. He was seized suddenly with retention of urine in consequence of hypertrophy of the prostate. After fruitless attempts at catheterism, probably accompanied by the formation of a false passage, the physician had aspirated the bladder and then had tried again to reach it by the urethra, but in vain. It had then occurred to him to practice suprapubic cystotomy, but he wished to make one more attempt at catheterism, and, in order to render it easier by doing away with pain, he had injected into the urethra about five drachms of a five-per-cent. solution of cocaine-in other

words, fifteen grains of cocaine. Almost immediately the patient's face became pale, he was seized with generalized tremor, and in a few seconds died of fulgurant syncope. There was no doubt that the death had been caused by the absorption of the enormous dose of cocaine introduced into the urethra. It was known, said M. Reclus, that the urethral and rectal mucous membranes absorbed with great rapidity; therefore, doses of from half a grain to 0.6 of a grain should not be exceeded when there was occasion to anæsthetize mucous surfaces. Diseases of the heart and arterio-sclerosis were not contraindications to anæsthesia by cocaine; on the contrary, the speaker thought that this substance was much less dangerous than chloroform in such cases-carefully managed, it was innocent. So had he been able to do 2,774 operations with cocaine without observing the least accident. M. Bazy remarked that, inasmuch as the urethra would not hold five drachms of liquid, it was probable that the injection had penetrated into the bladder, which absorbed with very great rapidity. M. Verneuil remarked that the author had mentioned the bad condition of his patient's circulatory apparatus. That would have been a reason for employing a feebler dose of cocaine, for the patient was thus predisposed to toxic accidents. M. Tuffier thought that this immediate death could only be explained by an intravenous injection into the corpus cavernosum, for the mucous membrane could not absorb with that degree of rapidity.

Rumination in Man. - In the Revue de médecine for March there is an article on this subject by Dr. G. Lemoine and Dr. G. Linnossier, who have arrived at the following general conclusions: 1. Merycism should be divided into two forms, simple and pathological. The latter comprises three varieties-merycism of neuropathic origin with or without dyspepsia; merycism originating in dyspepsia and having a direct connection with it; merycism of dyspeptic origin, but continuing after the dyspepsia has been cured. 2. Merycism should be considered as in its nature a gastric neurosis. 3. The act of regurgitation is a reflex act the point of departure of which is a congenital or acquired exaggerated sensibility of the mucous membrane of the stomach. 4. The mechanism of this act resembles that described by Chauveau and Toussaint as occurring in ruminants. and consists essentially in spasm of the diaphragm and of the inspiratory muscles, which diminishes the intrathoracic pressure and tends to dilate the œsophagus, while the abdominal muscles compress the stomach.

Poisoning with Salol.—At a recent meeting of the Paris Société de thérapeutique, a report of which is given in the Mercredi médical for March 21st, M. Josias spoke of a case of acute amygdalitis in a girl, eighteen years old, in which he had prescribed fifteen grains of salol to be taken the first day and thirty grains on the following day. Soon a large patch of scarlatiniform crythema showed itself on the inner aspect of the right thigh, while spots looking like those of measles appeared on the left side, and rose-colored papules on the cheeks. On examining the urine, the reaction of carbolic acid and that of salicylic acid were found. The use of salol was suspended, as the patient seemed to have a special susceptibility to it.

Iodide of Potassium in the Treatment of the Bronchopneumonia of Measles.—In the Journal de clinique et de thèrapeutique infantiles for March 22d there is an article on this subject by Dr. Bicente, who remarks that the treatment of various forms of broncho-pneumonia by means of iodide of potassium is no novelty. Furthermore, he says, it does not seem to have produced very favorable results with those who have used it. Nevertheless, he has been led to resort to it in the bronchopneumonia of measles. He had had occasion to administer

iodide of potassium to a child, eleven years old, presenting all the symptoms of tubercular meningitis, whose father confessed that he was syphilitie; and the child had recovered. This child's brother, during convalescence from an attack of measles, was attacked with an acute broncho-pneumonia of a suffocating character, which seemed destined to prove fatal speedily. The author gave the child iodide of potassium on account of the family history, and in a very few days it recovered. Not feeling justified in imputing the action of the drug to its antisyphilitic properties in this instance, the author resolved to try it in other children attacked with the broncho-pneumonia of measles and free from specific complications. The result, he declares, has been identical in a large number of cases. He says he has had failures, but they have seemed to him to be in cases of tubercular disease. He has therefore arrived at the following conclusions: 1. In the simple forms, where there is no tuberculosis, the efficiency of the remedy may be counted upon. 2. If there is no improvement in the course of a few days, its employment should be given up and the existence of tuberculosis inferred. He gives the iodide in daily amounts of from three to twelve grains, according to the patient's age. At the same time he uses one or more blisters. In spite of all that has been said against blisters, he remarks, they are a powerful agent, or at least a very useful adjuvant, and the same may be said of large sinapisms. The patient's strength should be kept up by means of grog, bouillon, and milk. A caution is given that if, after the child has shown decided amelioration, tremulousness and dryness of the mouth are observed, iodism is to be feared. In such cases a cure takes place at once on stopping the administration of the drug.

The Pennsylvania State Medical Society .-- The programme for the next meeting, to be held in Philadelphia on May 15th, 16th, 17th, and 18th, includes the following addresses and papers: Medicine, by Dr. W. S. Foster, of Pittsburgh; Surgery, by Dr. G. D. Nutt, of Williamsport; Obstetrics, by Dr. E. E. Montgomery, of Philadelphia; Mental Disorders, by Dr. T. M. T. McKenna, of Pittsburgh; Hygiene, by Dr. J. H. Wilson, of Beaver; Ophthalmology, by Dr. George de Schweinitz, of Philadelphia; Hydrophobia, by Dr. Charles W. Dulles, of Philadelphia; Dietetics, by Dr. H. F. Slifer, of Philadelphia; Unique Cases in Practice, by Dr. John M. Batten, of Philadelphia; The Therapeutics of Wooping-cough, by Dr. W. C. Hollopeter, of Philadelphia; Colorado Climate for Consumptives, by Dr. William P. Munn, of Denver; Subcutaneous Emphysema, by Dr. R. G. Curtin, of Philadelphia; Diarrheal Diseases, by Dr. John Aulde, of Philadelphia; Acroparæsthesia, by Dr. Wharton Sinkler, of Philadelphia; Typhoid Fever, by Dr. Adolph Koenig, of Philadelphia; Tapping of Abdominal Effusions as a Therapeutic Measure, by Dr. W. E. Hughes, of Philadelphia; The Radical Cure for Hernia, by Dr. E. Laplace, of Philadelphia; A Modification of Pirogoff's Amputation, by Dr. F. Le Moyne, of Philadelphia; The Surgery of the Gall Bladder, by Dr. X. O. Werder, of Philadelphia; Section of the Tendo Achillis in Fractures and Dislocations, by Dr. T. S. K. Morton, of Philadelphia; Appendicitis, by Dr. John B. Deaver, of Philadelphia; Amputation near the Ankle, by Dr. G. G. Davis, of Philadelphia; Stricture of the Urethra, by Dr. O. Horwitz, of Philadelphia; The Treatment of Fractures at the Lower End of the Humerus, by Dr. Charles W. Dulles, of Philadelphia; Acute Intestinal Obstruction, by Dr. J. M. Barton, of Philadelphia; Ocular Exploration of the Bladder and Urethra, by Dr. Edward Martin, of Philadelphia; Thyreoidectomy, by Dr. John B. Roberts, of Philadelphia; Puerperal Eclampsia, by Dr. J. C. McAllister, of Philadelphia; Uterine Fibroids, by Dr. Charles P. Noble, of Philadelphia; Acute En-

dometritis, by Dr. J. M. Baldy, of Philadelphia; Studies in Obstetrics and Gynæcology, by Dr. Anna M. Fullerton, of Philadelphia; Symphysiotomy and other Procedures, by Dr. Horace Fox, of Philadelphia; Cholecystenterostomy, by Dr. B. F. Baer, of Philadelphia: Corneal Ulcers, by Dr. S. L. Ziegler, of Philadelphia; Diseases of the Ear, by Dr. S. MacCuen Smith, of Philadelphia; The Surgical Treatment of Internal Strabismus, by Dr. H. F. Hansell, of Philadelphia; Eye Strain, by Dr. Charles H. Thomas, of Philadelphia; Tympanic Vertigo, by Charles Burnett, of Philadelphia; Massage Methods in the Relief of Tinnitus, by Dr. Louis F. Lautenbach, of Philadelphia; Capsulotomy after the Removal of Cataract, by Dr. L. Webster Fox, of Philadelphia; Intranasal Surgery, by Dr. W. H. Daly, of Pittsburgh; Naso-pharyngeal Catarrh, by Dr. William R. Hoch; Clinical Observations, by Dr. J. V. Shoemaker, of Philadelphia; Epithelioma of the Skin, by Dr. M. B. Hartzell, of Philadelphia; The Curability and Treatment of Tuberculosis, by Dr. S. Solis-Cohen, of Philadelphia; Psychical Phases of Tuberculosis, by Dr. J. M. Taylor, of Philadelphia; The Contagiousness of Tuberculosis, by Dr. A. M. Cooper, of Philadelphia; The Prophylaxis of Tuberculosis, by Dr. L. F. Flick, of Philadelphia; Medical Tuberculosis, by Dr. Hugh Hamilton, of Philadelphia; The Strychnine Treatment of Pulmonary Consumption, by Dr. T. J. Mays, of Philadelphia; A Case of Tubercular Meningitis, by Dr. D. Longaker, of Philadelphia; Tuberculosis of the Falloppian Tubes, by Dr. C. B. Penrose, of Philadelphia; The Treatment of Tubercular Caries of the Spine, by Dr. H. A. Wilson, of Philadelphia; and A Case of Tuberculosis of the Knee Joint, by Dr. E. B. Haworth, of Philadelphia. The following members will take part in the discussion on Medical and Surgical Tuberculosis: Dr. J. H. Musser, Dr. W. B. Ulrich, Dr. J. C. Wilson, Dr. J. Solis-Cohen, Dr. W. E. Hughes, Dr. J. B. Roberts, Dr. DeF. Willard, Dr. G. G. Davis, Dr. J. K. Young, Dr. J. M. Barton, and Dr. B. F. Baer, of Philadelphia. Tubercular Manifestations of the Skin will be discussed by Dr. H. W. Stelwagon, of Philadelphia. Further papers will be read as follows: On Christian Science and the Medical Profession, by Dr. Hildegard H. Longsdorff, of Philadelphia; Should the Journal of the American Medical Association be used to Promote Quackery? by Dr. S. Solis-Cohen, of Philadelphia; Reasons for the Revision of the Code of Ethics, by Dr. E. Jackson, of Philadelphia; and Cramming in Medical Schools, by Dr. O. H. Allis, of Philadelphia. There will be an exhibition of pictures illustrating leprosy in various stages of the disease.

The New York Academy of Medicine.—At the last meeting, on Thursday evening, the 19th inst., the paper of the evening was by Dr. Landon Carter Gray, on Persistent Albuminuria and Glycosuria in Functional Nervous Disease, and their Significance.

At the next meeting of the Section in Laryngology and Rhinology, on Wednesday evening, the 25th inst., Dr. Jonathan Wright will read a paper entitled A Consideration of the Vascular Mechanism of the Nasal Mucous Membrane and its Relation to Certain Pathological Processes.

At the next meeting of the Section in Obstetrics and Gynæcology, on Thursday evening, the 26th inst., Dr. Brooks H. Wells will read a paper on The Treatment of Abortion.

The Presbyterian Hospital.—At the annual meeting of the board of managers, held on April 11th, the several classes in neurology were united under one class head. Dr. Robert Safford Newton was appointed head of the class in neurology.

The Paris Faculty of Medicine.—The Union médicale states that M. Raymond has been elected a professor, to succeed the late M. Charcot.

## Original Communications.

## SOME DIFFICULTIES IN THE DIAGNOSIS OF CARDIAC DISEASES.\*

BY FRANK W. JACKSON, M. D.,

CHIEF OF CLINIC AND INSTRUCTOR IN PHYSICAL DIAGNOSIS, MEDICAL DIVISION OF THE COLLEGE OF PHYSICIANS AND SURBEINS, NEW YORK : ASSISTANT VISITING PHYSICIAN TO BELLEVUE HOSPITAL.

The diagnosis of most diseased conditions of the heart seems at the first glance comparatively easy, provided one has had the average training and experience in such conditions. A more careful study of the subject, however, reveals difficulties which are not commonly recognized or certainly are not recorded in the text-books, and which should be known to every practitioner. My notes upon cases of derangement of the heart observed during the past fourteen years are in many instances, to me at least, very interesting, and from these I have selected a few abstracts which, while only serving to indicate in a sketchy and imperfect manner some of the difficulties to be met with, may yet suffice to direct further attention to the subject.

To the superficial observer the presence or absence of a cardiac murmur is sufficient to determine the abnormal or the normal condition of the heart, but it is well known that the presence or absence of a murmur is only one element in the diagnosis. It is not generally known, however, that a murmur may be evanescent. The common belief is that a murmur once developed must be present continuously as long as the morbid condition which gave rise to it persists. This is not the case. A murmur may, and frequently does, appear and disappear and return again within a very few hours. Such evanescent murmurs are most commonly due to functional derangements of the heart, but they are also observed in connection with well-marked valvular lesions. This evanescent character of a valvular murmur was first brought to my notice in 1880, when I was an interne in the Roosevelt Hospital. A woman was admitted with a greatly dilated heart, but no valvular murmur. The house staff made frequent examinations of her heart, and after several days a systolic apex murmur was detected. The attention of our attending physician, a gentleman of distinguished ability in diagnosis, was directed to this murmur, but he disconcerted us by stating that he did not hear it. It was one against three; but it was one trained physician against three beginners, and we thought that we must have been mistaken. The examination of the patient's heart, which was instituted the moment the attending physician had left us, failed to reveal a murmur, but the next day the murmur returned. Again our attending physician failed to hear it. Happily on the third day we caught the murmur at the right time and our attending physician confirmed our diagnosis. A subsequent autopsy revealed a very marked insufficiency of the mitral valve. That case set me to thinking. Why was the murmur inconstant? It could not be on account of the weakness of the cardiac

A gentleman, aged twenty-eight years, of nervous temperament and slight physique, applied to one of the prominent life insurance companies of this city for a risk upon his life. He first came to me for a physical examination. As I had had an intimate medical knowledge of him for the previous three years, I assured him that he would have no difficulty in passing his examination; but to satisfy him I made a careful, not perfunctory, examination of his heart and lungs and of his urine. There was not the slightest evidence of anything abnormal, except that his pulse rate was a hundred. The heart sounds were clear and distinct and the heart was not enlarged. Knowing my patient's nervous temperament, I attributed his rapid heart action entirely to excitement, and I cautioned him to get the examiner to count his pulse before subjecting him to a general examination. Three weeks later he came to me and said that his application had been refused. Three examiners had listened to his chest and then declined his risk on account of "something wrong with his heart." I was surprised, for I knew the gentleman had no organic disease, and I proceeded to examine his heart again. My ear had hardly touched the chest wall before I heard a particularly loud systolic apex murmur. After explaining to him that there was no cause for alarm I directed him to report to me for examination once a month. I found that this murmur was sometimes present and sometimes absent, sometimes loud and sometimes very feeble. But up to a year ago. when he left New York, he never had a symptom of derangement of the heart, nor was there any increase in the size of the

During the past year I have had, and have still, under frequent observation a dispensary patient who, in addition to a well-marked aortic diastolic murmur, has a systolic apex murmur which is at times so loud as to be recognized by all my students, and yet on the following day it is frequently entirely inaudible.

Last summer there was admitted to the Roosevelt Hospital a man with unmistakable chronic fibrinous pericarditis. The characteristic "to-and-fro" murmur of pericarditis was so loud that it could be recognized at once either by the ear or the stethoscope. Yet that murmur would be found to disappear and reappear from day to day or even from hour to hour. In addition to this a blowing systolic endocardial-like murmur would occasionally be heard to the left of the situation of the apex beat.

muscle, for the heart was beating with equal strength both when the murmur was heard and when it was inaudible. I was inclined then to believe that the fault lay in our own ears, which at times were too dull to detect faint sounds; but I have since become convinced that this is not the case. Murmurs vary more than ears. The reason why they vary except in those cases where there is temporary variation in the force of the heart's action-is no more clear to me to-day than it was then. I have since met with many instances of cardiac disease in which a murmur could be heard at one examination and not at the next. It would seem that such variation in the cardiac murmur must occur only when the murmur is feeble in intensity; but this is not so; a loud murmur will often be observed to come and go. This noteworthy fact will frequently explain the discrepancy in the opinion of different physicians in regard to the same case. An interesting example of this difference of opinion occurred in connection with the application of one of my patients for life insurance five years ago.

<sup>\*</sup> Read before the New York Clinical Society, February 23, 1894.

Another source of error in the diagnosis of cardiac disease is the curious fact which is, I believe, almost altogether overlooked, that some murmurs are heard only by the unaided ear and are inaudible to the stethoscope, while some are inaudible to the ear and are heard with great distinctness by the stethoscope. This curious characteristic of murmurs may be noticed in any form of valvular disease, but it is most common in connection with the murmur of aortic regurgitation. This murmur, whether feeble or loud, is sometimes only heard by the ear and not by the stethoscope, while in other cases the murmur can not be detected by the ear alone, but is quite loud when heard through the stethoscope. I have no explanation to offer in regard to this peculiar phenomenon, but the fact is unmistakable. It will readily be seen how important it is that this should be recognized, for if the heart be acting regularly and an examination be made with the stethoscope alone the heart sounds might appear absolutely normal and thus a most serious valvular disease would escape notice. I make it an invariable rule in cases which admit of the least doubt to listen both with my ear and with the stethoscope. If there seems to be every reason to believe that the heart is healthy, I think it better to listen with the ear alone than with the stethoscope alone.

The fact that murmurs do not always confine themselves to their regular areas is still another source of error. We naturally expect to find the murmurs of aortic valvular disease in the neighborhood of the second intercostal space to the right of the sternum, or over the upper portion of the sternum itself; but this is not always the case. The murmur of aortic regurgitation, particularly, is often heard only over the ensiform cartilage, and the examiner who forgets this possibility may readily be deceived by listening only over the upper portion of the sternum, and, if he there hears a clear second sound, he may readily make the mistake of believing the aortic valves to be healthy. It must also be remembered that the murmur of aortic regurgitation may occasionally be heard at the apex of the heart only. A murmur heard in the neighborhood of the second intercostal space to the left of the sternum may indicate disease of the pulmonary valves or of the pulmonary artery; but disease of the right heart is so rare in the adult that it is hazardous to make such a diagnosis. The true condition is usually disease of the aortic valves or pressure upon the pulmonary artery. I ventured the diagnosis of disease of the pulmonary valves in a patient whom I saw this past summer at Bellevue Hospital, my reason for the diagnosis being the fact that she had the symptoms of malignant endocarditis, together with a loud, harsh systolic murmur, heard with greatest intensity over the situation of the pulmonary valves, while hardly any murmur could be heard over the aortic area. It is well known that malignant endocarditis, unlike rheumatic endocarditis, may attack the right heart in the adult. There seemed good reason to believe, therefore, that the murmur was produced in the pulmonary orifice. The autopsy showed that I was mistaken. There was malignant endocarditis, but the disease had involved the aortic valves, while the pulmonary valves were intact.

situation of the murmur of mitral stenosis. We are told that this should be heard only at the apex of the heart, but it is often inaudible at this point, and is only heard in the third intercostal space to the left of the sternum. I have also heard this murmur in the axillary region, considerably to the left of the apex beat, and nowhere else, and I have observed a harsh systolic murmur over the pulmonary orifice in a case which autopsy showed to be mitral stenosis.

Five years ago I was very much puzzled by hearing a double murmur over the situation of the liver. A man applied to the Medical Clinic of the College of Physicians and Surgeons for relief from the ordinary symptoms of heart disease. The peculiarity of his case consisted in the absence of any signs of enlargement or disease of the left ventricle, while the area of cardiac dullness to the right of the sternum and between the fourth and sixth ribs was considerably increased. A distinct, but not boud, double murmur was heard over the same area, but with its maximum intensity in the fifth space and the nipple line, or seemingly over the liver. Dr. Delafield's brilliant diagnosis of a small aneurysmal sac having its origin just above the aortic valve and projecting downward was confirmed by autopsy some two years later.

The fact that the presence of a murmur does not necessarily indicate valvular disease is generally recognized; but far too many physicians still regard a cardiac murmur and heart disease as synonymous terms. The subject is too extensive to be adequately dealt with within the limits of this paper; but it will be sufficient to call attention to the case, before mentioned, of the gentleman who applied for life insurance and was rejected on account of a mitral systolic murmur. During the five years since that murmur was discovered there has never been the first symptom of derangement of the heart's action, and there has been no increase of the size of the heart or other sequelæ of valvular incompetence. It is not uncommon to discover cardiac murmurs in patients who have never experienced the slightest symptom of derangement of the heart's action, and in many of whom no evidences of hypertrophy or other compensation can be found. The experience of examiners in life insurance will confirm this statement. A little leakage through a valve by no means destroys the efficiency of the valve, and, in the absence of evidence of progressive endocarditis, such cases should not be regarded as true heart disease.

The difficulty of diagnosis in cases of cardiac disease without a murmur is much greater. This applies particularly to disease of the aortic valves, or of the aorta just above the valves. The diagnosis of the dilated heart, or of cardiac weakness, is comparatively simple, since in these cases we have direct evidence of the failure of the cardiac muscle, and the presence or absence of a murmur signifies but little. Well-marked stenosis of the mitral orifice or of the aortic orifice, though often unattended by its characteristic murmur, is usually recognized without much difficulty. The class of cases of which I wish to speak particularly is that in which there is either atheroma or thickening of the aortic valve with atheroma of the aorta, or there is atheroma of the aorta in the neighborhood of the orifices of the coronary arteries without involvement of the aortic In a like manner we may be embarrassed or deceived by the valves. The difficulties in the diagnosis of some of these

cases is very great indeed, and yet they should be recognized if possible, since the prognosis is of the utmost gravity. It is a condition which occurs in New York more commonly than is generally known, and more especially among the upper classes. Most of my cases have been men of middle age, who have been in active business for many years, and who have worried over their business. These men complain for a considerable length of time of "dyspepsia"; then they have painful sensations about the heart, then palpitation of the heart, and, finally, dyspnœa on exertion. They are liable to sudden death, usually with symptoms of angina pectoris. In some cases the diagnosis is comparatively easy, but in others it is very difficult indeed. Two years ago two gentlemen put themselves under my care at about the same time and with very similar symptoms.

Each was over fifty years of age, and each was in active business. The first patient had suffered for several years from palpitation of the heart and flatulence, and these symptoms had distressed him so that he had lived for a year on a diet of hot water and chopped beef, but without material benefit. At the time he came to me he was building a house, and he found when he ascended the steep temporary stairs that he was short of breath, and that, as he expressed it, "there was a devil under his breast bone." Careful physical examination revealed an intermittent but strongly acting heart, a clear first sound at the apex, while no aortic valve sound could be heard. There were no murmurs. The apex beat was in its normal position, but auscultatory percussion showed the heart to be unquestionably enlarged. There was no increase of arterial tension and no renal disease. Several subsequent examinations showed that the aortic valve sound was persistently absent. There never was a murmur. Here, the enlargement of the heart and the absence of the aortic valve sound, the attacks of pain and dyspnæa on exertion, and the location of the pain under the sternum, rendered the diagnosis of disease of the aortic valve and of the aorta very probable, and the bad prognosis was confirmed by his sudden death with symptoms of angina pectoris a vear later.

The second patient had suffered for a long time from flatulent dyspepsia and an intermittent heart. For about a year previous to the time that he consulted me he had suffered from attacks of asthma and bronchitis. He was very nervous about himself, and especially in regard to his heart. He had taken many drugs.

Examination of his chest showed that he had moderate emphysema of the lungs. His heart was intermittent but fairly strong; all the valve sounds were normal, and auscultatory percussion showed no increase in the size of the heart; the apex beat could not be felt. There were no murmurs. Subsequent examinations revealed no change in these signs. There was no increase of arterial tension and no renal disease. This case I regarded as just the opposite of the former one. I considered his cardiac symptoms to be entirely functional, and I believed that his attacks of asthma were due to his emphysema superinduced by reflex conditions from his stomach. I gave an absolutely good prognosis. I stopped all medicine except some iodide of potassium and told him to go back to his business instead of spending his time in bed, as he had been doing. Within two weeks he improved wonderfully, and after about six weeks he came into my office one day to tell me how well he felt. His heart was regular; he had had no asthma for some time, and only complained of some shortness of breath on active exertion. The next day, while ascending the stairs of the elevated road, he complained of pain under his sternum, and then almost fainted. He was assisted to a neighboring drug store. When he sat for a moment, a small quantity of blood gushed from his mouth and he died. I could not obtain an autopsy, but I believed that all his symptoms were due to an aneurysm of the arch of the aorta.

I had been misled by the nervous character of the individual, which had induced me to underestimate the severity of his symptoms, and since to this was added a heart normal in size and strength and with absolutely no change in the valve sounds, I was completely deceived as to his true condition. The following is a typical case:

Last spring a gentleman was sent to me by his son, who is a physician, for advice as to the condition of his heart. He was sixty years of age; he had always been remarkably healthy, and he was a very active and hard worker. His only discomfort was an occasional attack of "biliousness." He considered himself perfectly well at this time, and he had only come to me to please his son. In 1892 his son noticed that there was an exaggerated heart action, and about the same time it was noticed that there was some little difficulty in breathing on ascending many stairs. Just before I saw him he had applied for an increase of life insurance, which was denied him, because, he said, his pulse rate was ninety to the minute. He denied to me that he ever felt ill except for some dyspeptic symptoms, and occasional attacks of slight pain running down the left arm. I found distinct hypertrophy of the heart, a very feeble aortic valve sound, and no cardiac murmurs. At that time there was no increase of arterial tension, but there was some thickening of the radial artery. The pulse was slightly intermittent. There was no renal disease. The age of the gentleman, the enlargement of the heart, and the feeble aortic valve sound, together with the pain running down the arm and the thickened radial arteries, led me to give a very unfavorable prognosis. Subsequent examinations both by his son and myself failed to reveal a cardiac murmur, but after three months a moderate increase of arterial tension developed, and he complained of dyspnea and discomfort after eating, which was relieved by eructations of gas. He continued at his business and insisted that he was perfectly well. On the evening of December 17th he suffered from dyspnæa on exertion, having to rest four times in walking half a mile, and he reached home exhausted. After a few minutes' rest he ate heartily and his symptoms disappeared. He retired to bed at 11.30 P.M. About 1 A.M. he complained of dyspnœa and pain in the region of the heart; there was eructation of gas and there was profuse perspiration. The pain and oppression became intense, and he died at 1.30 A. M.

It will be seen that these cases do not resemble angina pectoris except at their termination, and that for a considerable period before death the symptoms are slight or obscure. It seems to me that the most significant signs of this condition are enlargement of the heart and an absence of the aortic valve sound, or a feeble aortic valve sound, though both these signs may be absent.

Still another source of error in the diagnosis of heart affections is to be found in the estimation of the size of the heart. Many hearts have undoubtedly been regarded as diseased which were absolutely healthy, simply because the apex beat was farther from the median line than is commonly the case, or because percussion revealed a larger area of cardiac dullness than the books would lead us to ex-

In the beginning of my experiments in auscultatory pect. percussion I believed that I had discovered a number of enlarged hearts, and I was disposed to criticise those gentlemen under whose care the patients were for not observing the enlargement of the heart, or for not discovering the nephritis or other cause of the enlargement. Further investigation showed me that these hearts were only of normal size, and that I must modify my preconceived ideas of the size of the heart as revealed by percussion. The left border of the heart is, in the healthy individual, much farther to the left than is usually supposed. It is commonly regarded as being about a quarter of an inch to the right of the left male nipple, and it is believed that much increase of the area of dullness beyond that point indicates enlargement of the heart. As a matter of fact the line of the left border of the heart usually runs through the areola of the male nipple and often to the left of the areola of the nipple. Repeated examinations of the size of the heart by percussion and by palpation of the apex beat have convinced me that the latter is the more reliable method of estimating moderate increase in the size of the heart; but even here the opportunities for error are numerous. The general rule is that the apex beat in the healthy adult heart is to be found an inch to the inner side and two inches below the left nipple, and that an apex beat below that point or further to the left indicates that the heart is either enlarged or displaced. This is, however, a very poor rule, for, in the first place, even the male nipple is subject to great variations in its position, both vertically and as regards the midsternal line; and, in the second place, the heart itself is movable in the chest and the apex may occupy different positions at different times, depending upon the position of the body. I have frequently felt my own apex beat, while lying upon my back, within the nipple line, and then, upon turning upon my left side, I have felt it half an inch to the left of the nipple line. It is better to estimate the distance of the apex beat to the left of the midsternal line than to compare its position with the nipple. Such apex beats may be found in the healthy adult male in the erect position-from two inches and a quarter to four inches and a quarter to the left of the midsternal line, depending upon the size of the individual and the degree of development of the chest. When the apex beat is found to be four or more inches to the left of the sternum it might be outside of the nipple line, and if the heart's action were excited it might easily be mistaken for a hypertrophied heart. The knowledge that the heart's apex may normally be found beating to the left of the nipple line should save us from the error of a hasty diagnosis of cardiac disease in the absence of distinct symptoms of cardiac derangement.

In many cases the question as to whether a heart is to be regarded as enlarged or not is by no means a simple problem, and its solution must be sought through a process of rational deduction, rather than by the direct evidence of physical examination.

I have observed in a few autopsies an error much more difficult to eliminate—namely, decided hypertrophy and some dilatation of the heart, without any displacement of the apex beat to the left or downward, and without increase of the area of cardiac dullness. Such cases are those in which the hypertrophy has developed especially in an anteroposterior direction, and, though the heart is enlarged, such enlargement does not reveal itself upon the surface of the chest. The obvious lesson from these cases is that in connection with, well-marked symptoms of heart disease, either with or without murmurs, the apparently normal size of the heart should not affect our diagnosis. It should also be borne in mind that we may have marked valvular disease without enlargement of the heart.

Attacks of palpitation or of intermittent heart action are commonly regarded by the laity, and sometimes by the physician, as indicative of heart disease; but it is well known that most of these cases are merely functional disturbance of the organ, and that in the absence of signs of enlargement of the heart, or of failure of the heart muscle, together with the presence of normal heart sounds, we can almost always make the correct diagnosis. But that such is not always the case is shown by the history of the gentleman cited above, who died suddenly from the exertion of ascending the elevated railroad stairs. In conditions of mitral stenosis especially, we are liable to fall into the error of regarding the palpitation of the heart and the irregular pulse as due to functional causes alone, since in connection with grave obstructive lesions of the mitral valve there is frequently no obvious enlargement of the heart and no murmur. In cases of doubt we must delay a positive diagnosis until we can assure ourselves of the presence or absence of signs of venous congestion or other evidence of failure of the normal circulation. Cases of functional derangement of the heart often assume startling and serious forms, and yet the prognosis is almost invariably good.

I have had under my care for the past twelve years a lady, now well on in years, who has suffered for over twenty years with attacks of very grave intermittence of the heart, often attended with syncope, but to-day she is without a sign of enlargement of the heart or murmur, or any evidence of failure of the heart muscle.

A young married lady had had several attacks of rheumatism, and following her first attack, ten years ago, she became subject to attacks of palpitation of the heart and syncope. She was told by two physicians that she had heart disease, and she was very apprehensive of her condition. She came under my professional care three years ago. I had known her for many years, and I always understood that she had heart disease, but I also knew her to be of a very active, emotional temperament. The knowledge of this latter fact, combined with the result of repeated examinations, which revealed a heart normal in size and action, with clear heart sounds, normal in every respect except for a slight prolongation of the first sound at the apex (which was undoubtedly due to the rubbing of the apex against the chest wall), and the fact that she had gone for ten years without dropsy or other signs of venous engorgement, enabled me to disregard the rheumatic history, and to express the positive opinion that there was no organic disease of the heart. The result has thus far justified the diagnosis, for she has given up the idea that she is an invalid, and for the last two years she has been entirely free from symptoms of cardiac derangement.

Some cases which are regarded as merely functional palpitation of the heart are undoubtedly examples of adherent pericardium, since this latter condition is perhaps the most difficult to recognize of all diseased conditions of the heart. Adhesions between the two layers of the pericardium are frequently discovered at autopsy, although they had not even been suspected during life.

It would seem that the secondary congestions resulting from a dilated or weak heart would invariably be referred to their proper source; but it is easier to overlook this than one would at first suppose. Cases of acute dilatation of the heart without endocarditis are those which are most liable to lead one into error. Here the symptoms of interference of the functions of the stomach and liver may assume such prominence as to entirely overshadow the breathlessness and palpitation which would otherwise direct our attention at once to the heart, and even though the heart be examined the absence of a murmur and the absence of a rheumatic history may entrap the unwary.

My attention was once directed by a physician of ability to a man who had suffered from jaundice for over a year and in whom the liver was found to be considerably enlarged. The history which had been obtained was purely one of derangement of the functions of the liver and stomach. A physical examination of his chest revealed a dilated and hypertrophied heart without evidence of endocarditis, and a few questions developed the fact that he had been taken with breathlessness at the same time that the jaundice appeared, and that some six months before dyspnœa and palpitation became so severe that he could not work or undertake any active exertion. He had, however, not thought much of these symptoms, but was much distressed by his jaundice and dyspnœa. Calomel and alkalies had failed to relieve, but rest in bed and cardiac tonics reduced the size of the congested liver and relieved all his symptoms.

The cases of atheroma of the aorta before referred to are often attended by symptoms of flatulence and other disturbances of the stomach, and so are liable to mislead us.

In some cases the symptoms are almost purely those of disease of the lungs, and we may be led into error by the absence of anything directly pointing to disease of the heart or aorta. This is particularly so in connection with a small aneurysm of the first portion of the aorta, which, giving no symptoms or physical signs in itself, may by pressure upon a bronchus produce cough and attacks of asthma. It is only by a complete system of exclusion that the correct diagnosis can be inferred, and then it is, of course, an inference only, and not a certainty.

Four years ago I saw in the wards at Roosevelt Hospital a man whose symptoms were those of emphysema of the longs and a very intense general bronchitis. He had frequent and severe attacks of asthmatic breathing, which I at first attributed to the severity of the bronchitis, but though the bronchitis cleared up the attacks of asthma continued, and even increased in severity, and I therefore suspected and looked for signs of an aneurysm of the arch of the aorta, but without result. I had him under observation for nearly two months, but could find no definite explanation of his asthmatic attacks. The attending physician who followed me also suspected aneurysm, but could find no definite signs of this condition. The patient died suddenly and an autopsy revealed an aneurysm of the ascending arch of the aorta and pressing upon the right bronchus.

In this connection the society will remember the case which I reported a year ago of the man in whom, without

symptoms characteristic of anything in particular, physical signs of fluid in the left pleural cavity were found, and when the chest was aspirated a large quantity of bloody serum was withdrawn. It will be remembered that no explanation could be found for the presence of blood in his pleural cavity, or even for the presence of a pleurisy. His sudden death made what was before very obscure perfectly plain. The autopsy revealed an aneurysm of the descending arch of the aorta and an old rupture through the lung into the pleural cavity. This rupture had become filled up by fibrine and the leakage stopped, till rupture occurred at another point and he died. In this case there was nothing upon which to base even a suspicion of aneurysm. His only symptoms were those of pleurisy with a bloody effusion.

Finally, cardiac disease may be overshadowed by acute disease of the lungs or by general diseases. This applies particularly to malignant endocarditis. Here the fever and erratic chills are liable to be referred to other sources than the heart, and that organ is overlooked, or the disease is mistaken for malarial poisoning. The presence of a cardiac murmur and the purpuric eruption, or other evidences of hæmorrhage, will usually direct attention to the true nature of the disease, but these signs may be absent. I had a case at the Roosevelt Hospital last summer which illustrates this point.

A patient was admitted with signs of consolidation of the lower lobe of the right lung. It was then noted that there was a soft systolic apex murmur, but there was nothing else to indicate disease of the heart and the murmur was disregarded. When I saw him he had been under observation a month or more, and the signs of consolidation of the lung had not diminished. Three weeks previously he had begun to have very great fluctuations of temperature; the temperature would rise to 105° or 106° in the evening and then fall nearly to normal in the morning. There was also considerable sweating. I heard no cardiac murmur, and in the presence of distinct evidence of involvement of the lung the idea of disease of the heart never occurred to me. The diagnosis seemed to me to lie between an empyema, an abscess of the lung, and acute tuberculosis of the lung. Several deep explorations of the lung with an aspirating needle failed to discover pus, and the examination of the sputum failed to reveal the presence of tubercle bacilli. He died one week later, and the autopsy revealed an unresolved pneumonia and very marked malignant endocarditis, with vegetations upon the tricuspid, mitral, and aortic valves-a condition which would seem impossible to occur without the presence of loud murmurs.

I believe that such murmurs must have been audible most of the time, and that had I examined the heart subsequently to my initial examination I must have heard them. An analysis of a number of cases of heart disease occurring in the wards of Roosevelt Hospital in which vegetations upon the aortic and mitral valves were shown to be present by post-mortem examination demonstrates, however, that in many cases no murmurs were heard, and I derive considerable comfort from this circumstance. The case is, however, an interesting and instructive one as showing how completely disease of the lung may overshadow the more serious disease of the heart.

# THE MODERN TREATMENT OF ILÆMORRHOIDS.

By JAMES P. TUTTLE, A. M., M. D.,

ADJUNCT PROFESSOR OF SURGERY AND LECTURER ON DISEASES OF THE RECTUM AT THE NEW YORK POLYCLINIC.

That hæmorrhoids can rarely be cured without an operation is far from the truth; equally so is the doctrine disseminated by quacks and advertising specialists, that the disease can always be cured without surgical interference. Certain forms of the disorder are amenable to the simplest constitutional and local treatment, while others can only be permanently relieved by the radical removal of the hypertrophied, prolapsing tumors. Only a clear appreciation of the different varieties of the disease will enable us to determine the proper treatment for any individual case. The operative measures are more brilliant and more remunerative than the others and are generally successful; but in many cases, I might almost say the majority, they are unnecessary. The comfort of the patient and his eventual usefulness will be equally conserved by less radical measures.

The old division into external and internal hæmorrhoids is still generally adhered to by surgeons and rectal specialists. This division, natural and distinctive, has a twofold meaning. External hæmorrhoids are those developing outside of the external sphincter muscle and clearly in view; they are also those originating in the inferior and middle hæmorrhoidal vessels, and are therefore connected with the general circulation. Internal hæmorrhoids are those inside of the external sphincter and out of view, unless prolapsed; they develop from the interior or superior hæmorrhoidal vessels, and are connected with the portal circulation. It is maintained that these may arise from the middle hæmorrhoidal veins, but I do not think the claim can be established. There is a class of hæmorrhoids which develop just upon the anal margin, neither without nor within, sometimes denominated mixed hæmorrhoids, which probably do originate in these vessels, but they are truly external piles, and will be discussed under that head. A clear appreciation of these different varieties and their origins is most essential to our success in their treatment.

External Hæmorrhoids.—There are four varieties of these—viz., thrombotic piles, varicose piles, inflammatory piles, and connective-tissue piles,

Thrombotic piles are small round or oval tumors, usually just beneath the skin or mucous membrane. They are due to coagulation of blood in a dilated hæmorrhoidal vein, or to the rupture of the vein, with consequent extravasation and clotting of blood in the cellular tissue. They are painful at first, owing to unusual tension, but the pain generally subsides, and the clot is usually absorbed, leaving only a slight induration. If irritated, however, these piles may set up a cellular inflammation or phlebitis, which will eventuate in marginal abscesses or subtegumentary fistulas.

Treatment.—Cold applications are said to give relief to the pain in these cases, but I have found a sponge, wrung out of very hot water and firmly pressed upon the parts, much more effectual. The radical treatment of this class

of piles is so certain and simple that it is never well to temporize with them. Having anæsthetized the parts by a hypodermic injection of cocaine, or by the ether spray, lay the tumor open in the line of the radial folds, and turn or scrape out the clot thoroughly. Then wash the cavity out with a bichloride or boric-acid solution and pack with iodoform gauze. There is no necessity for styptic applications; pressure will control all bleeding, and after twenty-four hours the packing may be removed and the parts be allowed to heal. I have operated on two thrombotic hæmorrhoids above the external sphincter in this same manner without packing even, and there has been no hæmorrhage. The simplicity and certainty of this method should restrain us from ever temporizing with these little piles.

Varicose Hamorrhoids.—This form of external piles is composed of varicosed veins about the verge of the anus. They are seen more frequently in professional men, and women in the higher classes of society, than any other. They are due to constipation and prolonged straining at stool. There are generally no distinctly isolated tumors, but rather an anal coronet of varicosed, tortuous veins. After defectation or straining they swell and become very prominent, thus causing rather an uneasiness than pain. This passes away as soon as the straining has ceased and normal circulation is established.

Treatment.—When uncomplicated, these hæmorrhoids never require an operation. The patient's bowels should be carefully regulated; he should avoid prolonged sitting at stool. After each operation and at bedtime he should lie down upon his side and apply firmly to the parts a sponge frequently dipped in ice water. After this he should apply an astringent ointment spread upon a piece of soft lint, and retain it in position throughout the night. I have found no ointment better than the following:

Under this treatment they will disappear and the patient's anus become as well as ever.

If from any complication, such as fissure or some other variety of piles, an operation should be necessary, these various hamorrhoids may be operated upon at the same time by excising the more prominent portions of the varicosities either by scissors, crushing, or the clamp and cautery. The latter method is quite painful in these cases, owing to the involvement of the cutaneous tissue. I have frequently cured this variety of piles by making cross sections of the ring of veins at several points with the Paquelin knife heated to a dull red heat; the subsequent pain, however, is a scrious objection to this method. The operation by crushing is much less painful and equally effectual. I have not tried puncturing the tumors with a fine-pointed Paquelin tip, as advised by Dr. Kelsey, having heard of several cases of abscesses produced by this method.

In a number of these cases, where I could not trust the patient's faithful attention to the regimen detailed above, I have injected the varicosities with a modification of Shuford's solution. The most thorough antisepsis should be practiced in making these injections. The needle should

be introduced into the varicosities while distended, the blood should then be pressed out, and the fluid injected. No more than four minims should be used in a single injection, and usually only two minims. So far I have had nothing but the most satisfactory results—no sloughing, no abscesses, no inflammation to speak of—in this class of cases.

Electrolysis is said to be effectual in this variety of hæmorrhoids. I have tried it in only two cases, both of which were failures. Where there is no complication, however, demanding anæsthesia, the application of cold sponge compresses and astringent ointments, and the regulation of the patient's habits and bowels, will effectually cure almost every one of these cases.

Inflammatory External Hamorrhoids.—These tumors develop at the verge of the anus, and originate in the inflammation and swelling of the anal folds. They are called by Cripps ædematous piles. They have a mucous and muco-cutaneous covering, and are composed of distended arteries and veins and considerable connective tissue, with more or less serous effusion. They are more or less clubshaped, their small ends extending within the external sphincter. They may be single or multiple, sometimes entirely surrounding the anus. They are due to traumatism or irritation, either from within or without the rectum. Anal or rectal ulcers with irritating discharges, proctitis, fissures, chancroids, improper toilet material, rough or too vigorous wiping, careless use of the enema tube, pederasty, rectal masturbation, rough chair seats, and hard fæcal masses may all produce them. They develop rapidly, are very painful, and when severe produce in the patient the constitutional symptoms of inflammation. Where there are more than one we are very likely to find a small fissure between them.

The distress occasioned by this variety of piles is out of all proportion to their external appearances, and as they may proceed to suppuration and all its consequences they can be said to be positively dangerous to life. However, this is an extreme view to take of them, for it is very rare that they produce disastrous results. Nevertheless, there is no other form of hæmorrhoids that so completely disables one.

Treatment.—The cause of these piles should, of course, be sought out and removed, if possible. After this two methods of treatment are open to us-the radical, or operative, and the palliative, or antiphlogistic. Where the disease is associated with internal hæmorrhoids or fissure, the operative method should always be selected, for the relief is immediate and the cure of both disorders certain. Operators are agreed that no advantage is gained by waiting for the inflammation to subside. One must be careful, however, in operating, when the tumors are much swollen, not to take away too much cutaneous tissue, and thus invite contraction. Having determined to operate, there is very little choice, so far as these hæmorrhoids are concerned, between the ligature, excision, crushing, or clamp and cautery methods. If internal hæmorrhoids are to be removed at the same time, I employ the clamp and cautery; but if there are none of these, I generally use the crusher or excision.

Whether the clamp and cautery or crusher are used, we should always dissect up the cutaneous attachment of the tumors with scissors, thus forming a sort of pedicle to which the clamp is applied, leaving a smaller mass of tissue to cut through, and at the same time avoiding the pain caused by burning the sensitive skin. It is advisable to stretch the sphincters and remove the internal hæmorrhoids first, although this is not an invariable rule. It is not proper to remove one of these tumors with an internal hæmorrhoid en masse, for it involves the destruction of too much tissue. By removing them separately we leave little strips or islets of mucous membrane around the anal margin, which are valuable safeguards against stricture. If there are no complications, such as fissure and internal hæmorrhoids, these piles may be removed under cocaine instead of general anæsthesia. A few drops of a four-percent, solution are injected along the base of the tumor; the latter is dissected up and crushed or tied off almost painlessly. There is no danger from hæmorrhage in these cases, for the vessels are all in view and can be easily caught up and tied; but this is rarely necessary, as pressure usually suffices. A neater and more surgical method is to clip the tumors off with scissors and bring the edges of the wound together by firm catgut sutures.

Where the pain is not severe, and where for any cause an operation can not be done in this class of cases, much relief can be obtained by the cold sponge applied as described above. About fifty per cent. of hamamelis added to the water thus used increases greatly its efficiency. The patient should lie upon his side in bed with his hips elevated. When the cold is not being applied he should keep upon the parts a layer of the ointment given above, to which may be added sulphate of morphine, one to three grains to the ounce. By these means the pain will generally disappear within the first twenty-four hours, and the swelling will gradually subside, leaving the radial folds thickened, indurated, and more prominent, always ready to inflame again, but painless until that occurs. Leeching and puncturing only add fuel to the flames, and the efforts frequently made to keep these tumors within the sphincter are as unwise as they are painful. They belong outside and should be left there.

After the inflammation in these tumors has subsided they should either be treated by persistent cold applications and careful regimen, or they should be snipped off with scissors, having been cocainized. After operating with this drug we should always be on our guard against hæmorrhage occurring about one to three hours subsequently. The vessels which are contracted by the drug relax as its effects wear off, and bleeding of alarming character sometimes occurs.

Connective-tissue Hæmorrhoids.—This class of piles, called also cutaneous piles, skin tabs, condylomata, etc., is the last division of the external hæmorrhoids. They are composed of hypertrophied tabs or masses of connective tissue about the margin of the anus, having a mixed cutaneous and muco-cutaneous covering. They are due to irritation and consequent hyperæmia of the parts. They may result from varicose, inflammatory, or thrombotic piles, or

from more serious disease within the rectum. I shall not here discuss their relations to specific or malignant disease, further than to say that I have seen them in both disorders and also unassociated with any other disease of the rectum whatever. I do not therefore consider them to be reliable evidences of any particular disorder. In their quiescent state they cause little inconvenience beyond the difficulty of thoroughly cleansing the parts. They are liable, however, to become inflamed from very slight traumatism or irritation of the parts. When this takes place they swell and become exceedingly painful, sometimes ulcerating or sloughing, and producing all the constitutional symptoms of inflammation and suppuration. The vascular element in these tumors is very small, they being largely connective-tissue growths.

Treatment,—Careful attention to regulation of the bowels and rectal hygiene, the application of cold to the parts, and the avoidance of injury to them will keep these piles in a quiescent state, but will not cure them. Even advertising quacks do not profess to take them away without operation. If they do not annoy a patient they should be left alone; but where they do, they should be removed. It is far better to remove them when quiescent than when inflamed, although excellent results may be obtained in the latter state, and patients will submit to operation when suffering pain who would not think of it at another time. We operate either by crushing, clamp and cautery, or scissors. Unless the tumors are very large, the simple clipping of them off with scissors is the most satisfactory. The clamp and cautery offer a sense of security against hæmorrhage in removing large inflamed masses. I prefer, however, to use the palliative treatment described in the last section until the inflammation and ædema have largely subsided, and then to remove the tumors either by scissors or crushing. General anæsthesia is rarely necessary in these cases, the four-per-cent. solution of cocaine acting quite efficiently. The only after-treatment is antiseptic cleanliness about the parts. If the piles have not been very large ones, the patient may go about his occupation on the next day, wearing a T-bandage, with antiseptic dressing to the parts.

Having spoken of the various operations in external hæmorrhoids, it is but frank to say that so far as the patient's comfort is concerned, it is rarely necessary to use any of them, if we except that for thrombotic piles. The palliative treatment will relieve all present symptoms, and keep the patient comfortable and fit for his work in life. If he prefers to follow out these measures, knowing that they are palliative, rather than undergo the radical cure, he should have this privilege, and the large majority choose it. Whatever course is pursued, however, antiseptic cleanliness should be as strictly observed here as anywhere else in the body.

Internal Hæmorrhoids.—Numerous and long divisions of this variety of piles have been made by the older writers, but practically there are only two—viz., capillary or nævoid internal hæmorrhoids and varicose internal hæmorrhoids

All hæmorrhoids have, of course, an arterial supply.

Those denominated "arterial" by Allingham and others are such as are supplied by more than one artery, and in which these vessels and their accompanying veins have become varicosed. From a practical point of view, however, they are only varicose hæmorrhoids, and are treated in precisely the same manner. The columnar piles described by Hamilton are simply hypertrophies of the pillars of Glisson. They contain more connective tissue than the ordinary internal hæmorrhoids, but are composed largely of varicosed vessels, and come properly under the second division.

Capillary hamorrhoids consist of a superficial vascular area, situated upon the surface of the rectal mucous membrane. The tumors, which are generally very small, are composed of the terminal branches of the superior hæmorrhoidal arteries and veins and their connecting capillaries. The walls are thin and bleed easily upon touch, or upon the passage of hard fæcal masses. The hæmorrhage from them is not generally so profuse as from the varicose variety, but it is more frequent and continuous, and may be repeated day after day for years in strong, healthy persons, without any sensibly bad effect. It is this form of bleeding that has given rise to the popular fallacy that hæmorrhages from piles are salutary. They can not be made out by touch, but generally they come into view when the patient strains and the rectum is everted by the thumbs of the surgeon. Sometimes they are too high up for this, however, and the use of the speculum becomes necessary. I have found the small size of my own modification of Cantrel's speculum (Fig. 1) the most satisfactory for this purpose. I wish to

call attention to a fact noticed in these cases—viz., that the point of hemorrhage is not generally at the summit of the tumor, but nearly always in the sulcus at the point of junction with the normal mucous membrane. I believe it is due to this fact that cauterization often fails to check the bleeding; the cauterizing agent, being applied to the summit, does not touch the offending point.

These tumors are too small for the use of ligature, crusher, or clamp, and must be dealt with in some other manner. The most usual method is by the application of chemically pure nitric acid to the bleeding point. This is generally effectual if the proper point is touched; but it has this objection: it is impossible to limit the action of the acid, and it sometimes leaves an ulceration considerable in size and very intractable. I have twice seen very intense inflammation of the rectum follow its use. Recently I have adopted in its stead the use of electro-cautery applied by a small, round platinum electrode. The application is more accurate, and the extent of cauterization much more under

control. The parts should be first cocainized either by simple application or by hypodermic injection of the drug. The speculum may or may not be used, according to whether the tumors come easily into view or not. The results in the cases treated so far have been all that could be desired, although I confess that five cases is too small a number upon which to base conclusions. These methods require no general anæsthesia, and are very acceptable to patients upon this account. The third method, advised by Dr. Bennett, of Fort Worth, consists in anæsthetizing the patients, dilating the sphincters, and scraping off the little tumors with a curette or Volkmann's spoon. I have had no experience with this method and can not speak of its efficiency, although I do not doubt it will accomplish the desired result. Nevertheless, it has the disadvantage of necessitating anæsthesia, which the other methods do not.

Varicose internal hamorrhoids are the ordinary simple internal piles. They may be associated with external hæmorrhoids, and when the two are united they form what are called mixed hæmorrhoids. It is not our purpose here to discuss their ætiology and pathology, further than to say many of these cases are due to constitutional and local causes, which, if properly treated or removed, the hæmorrhoids disappear. Intestinal indigestion, chronic hepatic congestion, catarrhal proctitis, prostatic urethritis, cystitis, urethral stricture, retroversion and prolapse of the uterus, rectal ulcerations, and neoplasms are frequently the causes of hæmorrhoids, and no treatment will give permanent relief to the rectal symptoms until these conditions have been removed or cured. Proper hygienic and dietetic management, with simple local applications, will give such complete and prolonged relief in overfed, inactive, plethoric individuals that I question if we are frequently justified in doing radical operations in such cases, especially in elderly people. Their diet should be limited and generally changed, alcohol should be interdicted or extremely limited, exercise should be increased and systematized, the functional activity of the bowels should be regulated, and prolonged application of cold should be practiced in the reclining posture, either through the rectal plug, irrigator, or sponge, at least twice a day. Enemata, it seems to me, oftener aggravate than relieve hæmorrhoids, although experiences differ in this regard. Where the liver is torpid or enlarged, an occasional blue pill at bedtime, or, perhaps better still, thirty grains of sulphate of sodium and ten grains of phosphate of sodium, taken in hot water before breakfast, with five minims of nitrohydrochloric acid after each meal, yield the most satisfactory results.

When such measures fail, operations of some kind become imperative. Of the large variety of these I shall only mention five-viz., injection, clamp and cautery, crushing, ligature, Whitehead's.

The first has been so generally and persistently condemned by surgeons that it requires some moral courage to indorse it, yet it has its field, and, when properly used, gives us some of our most satisfactory results. In simple internal varicose hæmorrhoids, where there is no ulceration, and where the sphincters are comparatively relaxed, the

and experience, however, to apply it properly. Its aim and object, as I use it, are to produce inflammatory induration in the hæmorrhoid, and subsequent absorption. As applied by some, with a view of producing sloughing of the tumor, it is, to my mind, unsurgical and dangerous. The tumor should be brought into view without a speculum, if possible, thoroughly cleaned, and the needle introduced from the base into its center. The blood should then be pressed out, and the fluid injected in very small quantities into different points of the hæmorrhoid through the one puncture. Four minims is as much as should ever be injected into the largest hæmorrhoid at one time, and two minims are generally sufficient. The solution which has given me most satisfaction (a modification of Shuford's) is as follows:

Ŗ	Ac. carbolici f 3 jss.;	
	Ac. salicylici 3 ss.;	
	Sodii biborat 3 j;	
	Glycerini ad f \( \frac{7}{2} \) j. M.	

It will be observed that the solution contains less than twenty per cent. of carbolic acid. It produces no pain, does not confine the patient, and if it does not radically cure, it certainly obtains for the patient long immunity from annoyance. I have treated many cases by this method under the promise that if it did not succeed they would return and have the radical operation done, but so far only two have come to the radical measures. Sometimes it is necessary to inject a large hæmorrhoid more than once. The repetitions should be made about three weeks apart. Occasionally I have had slight sloughs, but I am confident they have been due to foreign matter carried in upon the needle, or to introducing the fluid too near to the surface. There is nothing in the fluid to produce suppuration. In the two cases which I have operated on by other methods, after injection, the inflammation set up was so unusual and the pain so severe that the patients sought relief by any means, and this I could promise them by radical operation. The tumors in these two cases when removed were swollen, tense, and much inflamed, but contained no pus. Whether they would have produced abscesses or not, it is impossible to say, but one thing is certain, neither of them was a typical case for this method of treatment, and I had unwisely yielded to the patients' desires for non-operative treatment. I have never had a death, hæmorrhage, fistula, fissure, stricture, protracted ulceration, or any serious result due to this method in over a thousand injections, and I believe that this experience is due to these precautions-viz.: antisepsis, weak solutions, and the small quantities of fluid injected.

The statistics furnished by Dr. Andrews and Dr. Mathews are drawn from the work of uneducated quacks and tyros, who used the method in all sorts of cases indiscriminately, and are, therefore, worthless. Those of Dr. Kelsey are from his own experience, generally with strong solutions, without antisepsis, and with comparatively large injections. They can not apply to the method as above detailed. As to the permanency of the cure it is questionable. Some cases recur in two to four years, but a secondary treatment is as effectual as the first; the large majormethod is eminently successful. It requires some skill ity, however, have no return, and if we can keep our

patients comfortable so long by so simple a measure, it is certainly worth trying, in properly selected cases.

Clamp and Cautery.—Where the sphincters are contracted, the hæmorrhoids prolapsed, painful, and large, and where there are fissures or ulcerations, a more radical operation than injection becomes necessary. In such cases the clamp and cautery operation is a most excellent procedure. Since Mr. Smith began to advocate this method it has steadily grown in favor until it bids fair to supersede the old and justly popular ligature, and become the accepted radical, safe, effectual operation for piles. It has been so frequently described that I shall only refer to some points in the technique which seem to me important.

- 1. The piles should be counted and located before the sphincters are dilated. After dilatation the whole hæmorrhoidal area becomes so congested and swollen that it is difficult to outline the tumors perfectly.
- 2. The ordinary method of dilating by introducing the thumbs and dragging them forcibly and rapidly apart is too violent. It tears the mucous membrane and ruptures the muscular fibers rather than stretches them. I prefer introducing one finger after another slowly until all are in the rectum and then using the hand as a sort of conical bougie. By this method there is less traumatism to the parts and the paralysis of the sphincters is more perfect and permanent. After this the parts should be cleaned antiseptically.
- 3. The hæmorrhoids should be grasped by the clamp in a line parallel with the axis of the gut. Contraction and stricture from this operation are due to grasping the piles at an angle to this line, and thus leaving a circular cicatrix, which contracts and lessens the caliber of the gut. The horizontal cicatrix when it contracts draws the rectum upward and overcomes any tendency to procidentia. The hæmorrhoidal forceps (Fig. 2) facilitates this grasp, besides

making the operation altogether easier. It is introduced over the pile closed and parallel with the axis of the gut; when opened, the pile rides into it and is drawn down; the clamp is then applied in the line of its grasp, the pile cut off with scissors, and the cautery applied. The last point in the technique of this operation to which I wish to call attention is the application of the cautery. I have seen operators grasp large mixed hæmorrhoids with muco-cutaneous coverings in the clamp, and proceed to burn them off as deep down between the blades as the heated knife will go. There are two errors here. The cautery should never be applied to the cutaneous surface where it is possible to avoid it. Ninety per cent. of the pain following the operation comes from burning the skin. The skin tabs or cutaneous portion of the hæmorrhoid should be dissected off with scissors and the clamp applied to the pedicle thus formed. There is no danger of hæmor-

rhage from the part thus left unburned, as it is in full view, and any bleeding point may be grasped and ligated or controlled by pressure. Secondly, the cautery, when used at the proper points, should only be used at a dull red heat to char the cut surface from which the tumor has been removed. It is a protection against hæmorrhage and not a destroyer of tissue. The crushing produced by the clamp is also a protection against hæmorrhage, and if the tissue it grasps is burned away this barrier is lost. Moreover, this deep burning is liable to result in deep sloughs which are slow to heal.

The objections urged against this operation-viz., pain, hæmorrhage, stricture, and long convalescence-are, I believe, utterly unfounded. The writers on rectal diseases who are most severe in their condemnation of it show by their own descriptions that they have never mastered the technique of the operation. In over five hundred cases operated on by this method I have not seen a death, a hæmorrhage of any moment, or a contraction of the rectum, except where the tumor was caught transversely. The average period of convalescence is about twenty-five days: I mean by this, complete healing of the parts, but the patients are not generally confined more than four or five days. The bowels are generally moved on the third day by licorice powder or cascara sagrada, and a boric-acid enema is given after each movement. There is generally no necessity of packing after this operation, yet I am in the habit of dusting the parts with iodoform and placing a small strip of gauze over each point from which a tumor has been removed. A good compress over the anus and a snug Tbandage are all the dressing that is necessary. Patients are allowed to sit up after the third day, and are generally about their usual vocations within a week. While some patients may do well who are operated on without any previous preparation, it is certainly best to have the bowels thoroughly emptied and as aseptic as it is possible to make them. Any other course seems to me reckless surgery.

Crushing.—This old operation, recently revived by Allingham, Jr., consists in catching the pile in a powerful clamp with smooth, dull edges, and crushing it off. It is virtually the clamp and cautery operation with the cautery left out. In comparison with the latter operation it is only slightly less painful, and perhaps the parts heal a little more quickly, but it is certainly not so safe as to either hæmorrhage or sepsis. It is more difficult of performance and consumes more time. It is only applicable to small internal and to external inflammatory and connective-tissue hæmorrhoids, where the cautery would involve cutaneous tissue, and thus be very painful. I have used it in fifteen such cases, all of which did very well, but I confess to considerable anxiety after each operation. A strong Kelsey clamp serves every purpose of the Allingham crusher, and is much more easily applied.

Ligature.—The profession is so familiar with this operation that I shall only refer to it most briefly. In an experience quite limited compared with that of Allingham, Mathews, and many others, I have had no failures with this method, so far as cure is concerned. It seems to me, however, to possess the following disadvantages: viz., it

can not be made an aseptic operation; it requires considerable time; it is very painful, the patient often suffering intensely for a week or more; it necessitates the use of the catheter very often; it involves the danger of secondary hæmorrhage where the ligature has partly cut through and thus become loose; it is liable to leave ulceration and stricture, especially where the whole circumference is involved; and, finally, it confines the patient to bed for a considerable time. These objections are not vital, nor are they wanting to some degree in the other operations for hæmorrhoids. It is only a matter of degree, and in my hands the clamp and cautery operation has given fewer undesirable sequences than the ligature, and therefore I prefer it. Between the two methods-Allingham's and transfixion-the latter would seem the safer, as there is less danger of the ligature slipping off. This, however, is a rare accident, and does not weigh much in making our conclusions.

Excision, or Whitehead's Operation.—This operation, which has become so widely known by the name of its author, is the most recent candidate for favor in rectal surgery. It consists in dissecting off the mucous membrane and the subjacent piles from the muscular wall of the rectum, excising them, and stitching the edges of the skin and mucous membrane together. The theory upon which it is basedthe removal of the whole pile-bearing area-is promising enough. "If the offending parts be removed, annoyance from them will certainly cease," is the argument used for it. Even so; but in this area lies the circulatory apparatus of the rectum; there is a design in this convoluted mass of veins and arteries; they have a function to perform and are unlike the vermiform appendix—the sooner removed the better. The question arises, then, Can we excise this area with impunity? I am not convinced of this as yet; experience alone can teach us, and of this we have not had sufficient to determine it. I have done the operation a very few times, and so far as my own cases go the results have been ideal. I have seen a number of cases, though, in which they were not so good. Among the bad results which I have seen follow the operation are two cases of stricture, two of ulceration, and one of prolapsus with erosion, such as is described by Dr. Kelsey. Another result of this operation which I have not seen described consists of the apparent drawing up into the rectum of the cutaneous tissues about the anus, so that they became macerated, soft, and white; it gave the patient considerable pain, besides producing a feetid, disagreeable odor to the parts. It has also seemed to me that the mucous membrane of the rectum was drier, less supple, and more easily torn after this operation than before. Are these results due to the operation or the operator? The success of this operation depends upon many things-viz., perfect asepsis, the choice of the exact line for incision, a very accurate dissection, the absence of tension when the edges are brought together, and immediate union of the parts. Where there are so many pitfalls one is likely to stumble. Only perfection in its technique can establish its position as a surgical procedure. The time and skill necessary for its performance, the hæmorrhage, and the certainty of disastrous results where immediate union does not occur place this and this relation, so evident, is of such importance that

among the major operations. It should never be undertaken except by a practiced surgeon familiar with and equipped for his work. When excision by this method succeeds there is little pain, the convalescence is shorter than by any other method, and the results are most satisfactory to patient and physician. But the question is still unanswered, "Do these results justify the risk?" In cases with large hæmorrhoids surrounding the rectum and much procidentia, with relaxation of the sphincter, the operation will find its most useful field, and when its technique has been so perfected as to remove the many sources of failure, it may supersede the simpler and more rapid methods.

There are just two points in the operation not generally mentioned in the books to which I would call attention, both of which are calculated to shorten it and lessen hæmorrhage. After the muco-cutaneous tissue has been cut through, the hæmorrhoidal masses can be peeled out with the handle of a scalpel or dull-pointed scissors, except at a few points where adhesions occur. It is from these points that the hæmorrhage comes; the tissues at these points should be grasped by two artery forceps and cut between them, and the blunt dissection should then proceed. The second point is a suggestion made by Dr. Ware. When the dissection has been completed, a long clamp is placed upon the gut at the upper border of the portion to be excised. Long sutures are then passed about a quarter of an inch apart in through the skin, the clamped gut, and out through the skin on the opposite side. The mass is then cut off above the clamp, and the sutures are drawn out from the caliber of the gut and cut in two. They will thus form a row around the anus and can be quickly tied. I have not tried it as yet, but I am told the procedure greatly shortens the operation.

#### ON SYMPTOMATIC HETEROPHORIA.

BY JUSTIN L. BARNES, B. S., M. D.,

ADJUNCT PROFESSOR OF OTOLOGY, UNIVERSITY MEDICAL COLLEGE: ASSISTANT SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL; FELLOW OF THE NEW YORK ACADBMY OF MEDICINE, ETC.

My method of dealing with muscular anomalies, as exhibited in a study of some two hundred and fifty recent consecutive cases, leads me to urge a fourfold plan in dealing with symptomatic heterophoria: First, correct any refractive error; second, wait; third, experiment with prisms; fourth, tenotomy.

In precisely this order were managed these two hundred and fifty cases; and, while endeavoring to make due allowance for personal error, it is not unreasonable to claim that, occurring in private work alone, greater weight should be attached to the evidence they carry than would naturally be the case in hospital studies, where the care and responsibility are divided.

It is well known that there is an intimate relation between accommodation and adjustment in all binocular vision. This relation is interdependent and interinfluential. Any interference with the one function-entails, it is logical to assume, disturbance in the action of the other; we can scarcely fail to conclude that heterophoria, with its accompanying asthenopia, depends chiefly upon an inharmonious action on the part of these two elements due to fault in the one or in the other. It is my belief that the primal fault lies in an existing ametropia in the vast majority of instances.

Assuming at all events these premises to be correct, it will be my purpose here to set forth certain observations and conclusions pertaining to the muscle question, gathered, as has already been noted, from personal experience alone, and to submit them without bias, yielding at all points to their logic.

I shall not weary the reader with statistics, although the basis of this paper rests upon a most painstaking and elaborate schedule of these two hundred and fifty cases, for it is my wish to present conclusions rather than figures. Nothing may be more misleading than "statistics"; for, as in the story of the man who when asked to make out a table of data inquired as to which view of the question he was desired to prove, so we are in great danger of molding our statistics much after the manner of our faith. Behind the cold table of statistics are the many subtle details and opinions which make the analytical deductions the more valuable when the statistician and the observer are, as under the present circumstances, one and the same.

Much might be said of symptoms and consequences attending heterophoria, but in this connection the methods of diagnosis and management are alone strictly pertinent.

In the determination of the kind and degree of muscular error, I invariably use that instrument of precision the phorometer, which I consider to be as essential here as I do the ophthalmometer in refractive studies, for no one can eliminate with certainty his personal error in holding prisms. In the management of the phorometer I have for years taught classes in ophthalmology these cautions: (a) To invariably test first for hyperphoria, for this is a delicate test as a rule, involving a fine skill in detail, which is most liable to be erroneously determined when the muscles are fatigued from having undergone what I term the grosser tests. (b) To test in direct succession only alternate pairs-i. e., at one time a vertical pair, then a horizontal pair-never, for instance, testing abduction and adduction one immediately after the other, because at least four muscles are involved in the test for any two, and fatigue of an opposing pair enters here as a vitiating influence; in other words, I allow rest to take place, and gain this end by this alternate method of testing. (c) To never take an immediate answer, but to allow a short period of time, neither too long nor too short, and averaging about ten seconds, to elapse, in order to permit of such readjustment of the muscles as the latter are capable of exhibiting. (d) To make certain of the kind of diplopia phorometrically produced, using for this purpose a red-colored glass, this point being highly essential in observations of hyperphoria. (e) To explain carefully to the patient the idea of fusion; two lights must fuse to make a test; extinction of one light does not constitute a test. To do this I hold two ignited matches, one in each hand, before the subject, and, making their flames coincide, explain that fusion is taking place; then,

while again separated, I blow out the light of one match, which, leaving one burning, I explain constitutes extinction and not fusion; and then I call attention to the fact that it is fusion-like the former-that I am after, and not extinction. I have often in this way excluded error, and have been able to account for the great discrepancies between various observers of the same patient. (f) To have the candle light and the eyes of the patient on the same level, and within reasonable limits not to mind the exact adjustment of the head; for when adjustment of the head makes a considerable difference in the tests, I consider the condition present as indicative of paresis rather than of insufficiency. (g) To secure like conditions of light, time of day, etc., in a series of tests. (h) To determine if the tests for powers and for insufficiencies bear harmonious or contradictory relations; if they are of the latter, I conclude that I have by no means reached the bottom of the matter. (i) To never consider as final a single set of experiments, for repeated examinations are imperative; indeed, this inquiry is not one easily satisfied. (j) To confirm the tests by no one method alone, but by various other researches, such as by the use of the Maddox prism, the Maddox cylinder, and enlarged copies of the Graefe "dot and line" test placed at twenty feet distant, both horizontally as well as vertically. This latter test I have used for several years, and I can not recall that I have seen this idea anywhere mentioned or described. Recently I have had constructed a Maddox cylinder carried in a frame for use on the phorometer, and made so that it can be revolved on its axis into exactly vertical and horizontal positions; it yields very accurate results by this means.

My method of management, when I have determined the diagnosis of symptomatic heterophoria, may be further discussed under three heads: (a) Refractive; (b) prismatic; (c) operative.

Of emmetropic heterophoria I have nothing to say in this paper.

(a) Refractive.—Non-operative symptomatic ametropic heterophoria is, as a rule, successfully managed by a careful correction of the existing error of refraction and by time. And in this connection I wish to lay stress again upon the very great value and assistance of the ophthalmometer in connection with the older methods of detecting and correcting astigmatism. The ophthalmologist to whom this instrument is a stranger can not realize, until he has used it, its accuracy and labor-saving character.

The conditions of refractive correction and time fulfilled have resulted most favorably in fully two hundred of the cases of my present collection. I can not, therefore, lay too much stress on the value of correcting ametropia. The result in these two hundred cases, or eighty per cent. of the whole, is a most cogent argument in support of my belief that errors of refraction are most commonly at the bottom of symptomatic errors of muscular adjustment. Certainly this procedure is highly conservative, and therefore commendable, appealing to our common sense and satisfaction. It is also an eliminative feature in the selection of cases capable of further amelioration only through prisms or operative measures.

It goes without saying that very great pains must be taken not alone with the selection of suitable lenses, but also with the correctness of their grinding, centering, and adjustment. An invariable rule of mine is to inspect both the lenses ordered and their adjustment, requiring patients to report for this purpose.

The question of how fully ametropia is to be corrected has no invariable solution. In children, I generally order full, or very nearly full, correction; in young people, I decide upon correcting as much as is "accepted," encroaching upon the "latent" ametropia as far as possible and with the expectation of a fuller correction in a few months. It is well known that the relative accommodation being less than the absolute, a patient will very often accept more correction over both eyes simultaneously than singly, and I always try to take advantage of this fact. In adults, the accommodation, being less elastic, renders the problem far simpler than in earlier years, and it is often to be noted that patients of mature years will comfortably accept full correction for near work, if not for distance.

(b) Prismatic.—In connection with symptomatic heterophoria, I have been led to conclude that prisms serve chiefly as the means of temporary relief afterward to be discarded, or as a medium of diagnosis. For a long time I have ceased to prescribe them for permanent use. They serve somewhat in the same capacity as do crutches—i. e., they give support to weak muscles for a time, while the latter are recuperating from a period of overexertion, and in this connection I always order prisms of low degree, correcting but a portion of an insufficiency. In diagnosis I use them in preparation for contemplated operations, conceiving that they may be worn with great aid in determining the amount of heterophoria which gives rise to symptoms; for without their employment eyes are often in so strained a condition that we can not accurately determine exactly what is the true degree of the insufficiency, while by their action in giving support the eyes assume a state of calmness in place of irritability, and then we may discover that the degree of the prisms worn is a guide to the amount of heterophoria underlying the mischief.

It might then be inquired, why not order these prisms to be worn constantly? Indeed, it might be a good plan to do so; but I am of the opinion that we should, wherever consistent with good results, discard our crutches, and I am further convinced that we have the means at hand for so doing—namely, in judicious surgery.

Already, I have touched on the value of prisms used in office work. Upon their value in connection with the phorometer I need not further dwell.

As for their value in calisthenics I am much in doubt, though I am sure that they have served in this manner favorably in a number of these cases.

(c) Operative.—When a sufficient period of time under refractive correction has elapsed, and this time should not be less than six months under ordinary circumstances, without affording decided relief, and especially where, in addition to lenses, prisms are giving relief, I am in favor of surgical readjustment of the offending muscles. Though a seeming paradox, I am also in favor of this procedure

where prisms do not yield relief. Under both these circumstances I am a believer in the efficiency and expediency of tenotomy. I do not believe in tenotomies first and lenses afterward, but, as I have repeatedly asserted, in the reverse order.

In these two hundred and fifty cases tenotomy was performed upon only twenty patients—a very small percentage. After such eliminative measures as I have outlined, the number of cases subject to tenotomy is so small that I anticipate favorable results with a degree of certainty in which I am seldom disappointed. In an examination of these twenty cases I found such results as justified the measure in every case without exception. The only superiority of this fourfold method lies in its conservatism and elimination.

The technique of operation is comprised in the muchdiscussed "graduated tenotomy." This surgical measure has the advantages of very slight traumatism, ease of execution, and absolute certainty, in connection with the phorometer, of accurate surgical results. Indeed, done with care, even the dreaded "stitch" is usually avoidable.

When a sufficient effect can not be secured in a single operation without extensive cutting, I consider it highly detrimental to persist until the desired effect is attained, but believe that further results should be secured in a subsequent operation, deeming it wise that the correction of heterophoria should be divided between the muscles, instead of being sustained by surgery upon a single muscle. This may be done sometimes at the same sitting. It is, moreover, desirable to secure a slight overeffect in an endeavor to compensate for the contraction in healing.

Much has been said and written on this operation. Much has been said of the "latent" muscular error that appears, and that the heterophoric tests yield the same results after as before the operation. On account of the opposition in the associated action of the muscles and their counterbalancing influence, this may truly be a latent insufficiency that reveals after operation an apparent return to the original condition. Yet, on the other hand, it may be that these muscles do, in healing, become restored to their former position with unaltered leverage power. But relief is what follows the procedure when done after the eliminating processes. This relief is due either to the actual readjustment by surgery, or else to the enforced muscular rest, only temporary albeit, which follows the operation, much in the same way that eyes, inert during atropinization, afterward perform their duties in a proper manner, when before their functions were accompanied by asthenopia.

In the study of these two hundred and fifty cases I have certain special observations to present. In a recent paper by Dr. S. M. Payne is set forth an ingenious and plausible theory—to wit, that, where there is deviation horizontally alone, the ametropia is isometric, and conversely, where the deviation is vertical, with or without lateral tendencies, the refraction is anisometric. I have found this proposition to be true in a very large proportion of my cases, the number of exceptions being only thirty out of the whole series, or cighty-eight per cent, according with the law as enunci-

The ophthalmometer, I believe, will, with its accuracy and the more attentive use of the phorometer and its various adjuncts, hereafter greatly reduce the percentage of exceptions; and, moreover, we must remember that we can not be entirely certain of the accuracy in the subjective tests of our patients. The practical value of this theory teaches the importance of very accurate work in correcting ametropia, for it is the very slight degrees of astigmatism rather than gross errors that influence the law, and of the quality of astigmatism it is the "mixed" variety which plays the leading part. And it is to be noticed that, where exceptions to this theory occur in vertical deviations, the spherical lenses were isometric, as a rule, again showing the importance of discovering small amounts of astigmatism. Furthermore, the value of employing several methods instead of one is apparent from the fact of there being so many exceptions, which by their employment might have shown patients to be inaccurate judges, and the like.

Heterophoria I am in the habit of classifying, for convenience, under two general heads—heterophoria simplex and heterophoria complex. These hybrid terms apply, the former to lateral deviation and the latter to vertical insufficiency, with or without lateral tendencies.

Symptomatic heterophoria naturally occurs prior to the presbyopic period as a rule.

In my series of cases heterophoria complex occurs most frequently in astigmatism, as might be rationally expected, and, while far less often accompanying hypermetropia and myopia, it is to be found oftener in the latter than in the former. Here, I think, the explanation lies in the assumption that hypermetropia is a nearer normal condition than myopia. Generally, as is natural, esophoria was associated with hypermetropia and disappeared frequently under correction of the latter, while exophoria was usually found in connection with myopia.

It is noteworthy that hyperphoria was oftenest found in company with exophoria, and, as I have noted in other cases, in emmetropia the latter condition also prevailed, in conformity with the notion that emmetropia inclines toward myopia. In this connection it is curious to note that hyperphoria seldom occurs alone.

In the matter of operative interference, attention should be called to the fact that hyperphoria very commonly disappeared in these cases after the reduction of exophoria or esophoria, and *vice versa*.

The question of surgical measures in heterophoria has provoked in the past violent discussion and has led to extreme views both on the one side and on the other. I am convinced that the truth lies between these extremes. After having followed in the management of these cases my conservative eliminative plan, the remaining patients to be subjected to operation resolved themselves into what may be termed selected material, and the results of the method, as has been said, most happily justified these tenotomies. It has been contended that there was no alteration of muscular adjustment through the "graduated tenotomy." I believe that the contention touches not so much upon the method, but upon whether the tenotomy does secure any effect upon the adjustment. Surely it would be highly un-

surgical to endeavor to get an effect in any way other than in the usual "graduated" method-i. e., with cocaine (to secure the co-operation of the subject), the phorometer, light, and prisms. As to whether we can secure readjustment in this manner or not, I am of the opinion that it is entirely feasible. At all events the tenotomy, done according to the "graduated" method, and after my method of elimination, has afforded relief in my cases without exception. I do not mean extravagant relief, but relief supplementary to the underlying basic principle of refractive correction. It may be asserted that the correcting lenses would have been followed by the same results. In these twenty cases of my table relief was not secured, or was but partial, although plenty of time was allowed for results, before resorting to surgery. These cases, in which operation was advised and performed, were probably instances in which there had been long abuse of the eyes, or neglect, or in which an ametropia was not, until after a long period of time, the subject of concern. I noted that the amount of heterophoria was far greater in cases selected for operation than in the others. This may throw light on this point, for it is rational to assume that the longer the delay in seeking relief the greater will be the heterophoria and the more radical the remedy necessitated.

I very much regret that I do not know how to test a single muscle for insufficiency. Here I ought to say that I consider binocular single vision as an essential in distinguishing between heterophoria and paresis. And so, though I have without avail experimented on my own eyes in order that I might judge in person of subjective tests, I must fain content myself with the conclusion that insufficiencies are not pathological, but are really defects in leverage power due to malposition or to general debility; whereas, in the attempt to study a single muscle we trench on the ground of pathology—i. e., paresis.

In conclusion, I think I may say, as the outcome of these investigations, that the wise plan lies in the middle course, as I have outlined it, and that we shall seldom fail to afford relief by following this conservative method, without enthusiasm on the one side or prejudice on the other.

3 East Forty-first Street.

## A STUDY OF THE MINUTE ANATOMY OF FUNGOUS ENDOMETRITIS AND MYELOMA (SARCOMA) OF THE UTERUS,

WITH RULES FOR THEIR MICROSCOPICAL DISTINCTION.

BY CHARLES DIXON JONES, B.S., M.D., FELLOW OF THE NEW YORK ACADEMY OF MEDICINE. BRITISH GYNECOLOGICAL SOC.ETY, ETC.

The microscopist is frequently called upon to examine scrapings from the mucosa of the uterus, and upon the result of this microscopical examination largely depend not only the correct diagnosis of the case, but also the prognosis and its proper treatment.

The gynæcologist, meeting with a case of persistent hæmorrhage from the uterus, will first probe the uterine cavity, and, finding a portion of the lining membrane roughened or nodular, he will suspect the presence of so-called fungous or glandular endometritis, especially if the patient is somewhat advanced in age, or has had a miscarriage within several months. As soon as it is found that the mucosa is nodular he should explore the cavity of the uterus. This is best accomplished after rapid dilatation. An exploratory dilatation and curettement, followed by a microscopical examination of the specimen, should always be adopted prior to any radical operation, such as hysterectomy or removal of the appendages. The immediate cause of the hæmorrhage is frequently a removable one, and if the above described plan be followed, the powerful aid of the microscope is called in to clear up the diagnosis and set all doubts at rest. The gynæcologist thus arrives at an exact knowledge of the pathological condition, and his subsequent therapeutics will be placed on a scientific

With rigid antiseptic precautions the curettage is unattended by any risk, and no subsequent pyrexia need be feared unless malignant disease be present. The curetted tissue should be preserved in dilute alcohol or a half-of-one-per-cent. solution of chromic acid, and sent to the microscopist for him to examine in order to determine the nature of the disease.

According to the views held by the majority of gynæcologists at the present time, fungous endometritis, or
glandular hyperplasia, is considered to be the result of a
chronic formative endometritis, leading either to a simple
hyperplasia of the utricular glands or even to a new formation of utricular glands, as well as an increase of the surrounding myxomatous lymph tissue. For our pathological
studies of this disease up to the present time we are
chiefly indebted to Ruge and Veit, who have fixed and
firmly established in medical literature the term fungous
endometritis.

There are many objections, from a pathological standpoint, to the views held by these authors, the chief one
being that no other instance is known in which a chronic
inflammatory process leads to a new formation of glands;
then, again, in all other cases it is the connective tissue
which is invariably the substratum of all plastic or formative processes, and not the epithelial, the muscle, or the
nerve tissue. These considerations have induced Dr. H. J.
Boldt, of this city, to study microscopical sections made
from scrapings of the uterine mucosa as well as sections
from the uteri which he has removed in the operation of
colpo-hysterectomy on account of uncontrollable hæmorrhage.

Dr. Boldt's studies are not as yet completed, but he has kindly given me permission to refer briefly in this paper to the results thus far obtained by him, and has given me also the opportunity to examine the uteri and the microscopical sections which he made therefrom. The essential points of Dr. Boldt's researches thus far are "that we shall have to confine the term fungous endometritis to those cases in which there is present an augmentation of the lymph tissue of the uterine mucosa with a slight enlargement of the utricular glands—i. e., a widening of their caliber without any new formation of glandular structure." As soon as the latter feature can be established the term fungous endome-

tritis ceases to be applicable, and in its place we must substitute the name lympho-adenoma, this term being used to designate a tumor composed of newly formed lymph tissue as well as glandular structures.

In Fig. 1 I have illustrated a case of pronounced lympho-adenoma where the uterus was removed by Dr. Boldt on account of repeated hæmorrhages. (See Fig. 1.)

Fig. 1. -Lympho adenoma of the mocosa uteri (Boldt), the fungous endome tritis of authors

Here we observe that the mucosa of the fundus uteri is considerably thickened, producing nodular elevations of considerable size. Microscopical examination has proved this case to be a pronounced "lympho-adenoma," the term suggested by Dr. Boldt.

The symptoms of the two diseases under consideration can not in every single instance be clinically differentiated, both pathological conditions being sometimes combined in one and the same uterus. The nodules produced by fungous endometritis are but slightly elevated above the surrounding surface, whereas those of lympho-adenoma are markedly raised above the surface of the mucosa. Bleeding is a symptom common to both diseases. With the microscope, however, the differential diagnosis is easy. Thus in the acute stage of fungous endometritis we find the lymph tissue augmented to such an extent that the myxomatous reticulum of this tissue is rendered almost invisible and seems to have disappeared. As soon as the stage of chronicity is reached the lymph corpuscles gradually diminish in numbers, thus causing the fibrous reticulum to become more conspicuous. The final result of this disease is atrophy of the mucosa; it becomes transformed into, primarily, a myxofibrous and afterward a fibrous connective tissue, at the same time the utricular glands being much diminished in number, or are found to be entirely absent in areas of considerable extent, many of them having been transformed into cysts. At no time have I seen any new formation of utricular glands. In lympho-adenoma, on the contrary, the lymph corpuscles, as a rule, are not augmented to any considerable extent at any stage of the disease, but the utricular glands are found to be very much increased in number, becoming at the same time tortuous. branching, and having their caliber partly narrowed or partly widened to a considerable extent, sometimes to a degree which makes the glandular structures appear far in excess of the lymph structures.

Fungous endometritis, like any other inflammatory process, will sooner or later come to a standstill, terminating at last in atrophy, while lympho-adenoma, being a type of tumor, is always progressive, endangering life by repeated hæmorrhages, although strictly benign in character from a pathological standpoint. It is evidently this disease which some pathologists have termed benign adenoma, although they admit that this form of adenoma is rather prone to become malignant and change into cancer.

In both fungous endometritis and lympho-adenoma the microscopical specimens show an unbroken wreath of columnar ciliated epithelia, forming the linings of the utricular glands. Sometimes this wreath is found interrupted, and replaced by globular elements, which have originated apparently from the epithelia themselves, and they not infrequently penetrate into the caliber of the gland, causing it to be distorted and more or less obliterated. In such cases neither of the previously mentioned diagnoses is applicable, but the nature of the originally benign tumor has changed into a malignant sarcoma (according to Virchow's nomenclature), or myeloma, which term I would prefer, it being more in accordance with modern pathology. The word sarcoma means a fleshy tumor, and is therefore inapplicable according to the latest pathological views. The term myeloma, on the other hand, means a medullary tumor-a tumor composed of indifferent embryonal or medullary elements, which, since the publication of Virchow's descriptions and researches, we know is the true histological structure of sarcoma. The first investigator who drew attention to these peculiar changes of the utricular glands was Louis Heitzmann in 1887.\*

His discovery, however, seems to have attracted but little attention, since I have been unable to find any reference to it in the text-books. Only a few gynæcologists have, up to the present time, resorted to microscopical examination for the purpose of diagnosis, and, trusting the revelations of the microscope, have removed the uterus after the diagnosis of myeloma had been thus fully and certainly established. I have had several opportunities to examine such uteri after their removal by vaginal extirpation (one being a case of Dr. McDonald's, and the second one of my own operations). In these a thorough microscopical examination of the mucosa of the uterine cavity and the subjacent muscular tissue has verified the diagnosis of the microscopist, made from an examination of the gougings removed by the scoop previous to operation.

In further illustration, I have now in my possession the scrapings from the uteri of two other cases, in one of which (Dr. Mundé's) I am unable to give the further history of the case. The second is one of my own cases, and having only recently obtained the specimen, it is yet too early to report fully, as the patient is now waiting for operation.

The microscopical examination of tissue removed by the curette from the uterine cavity (in one of my cases, characterized by persistent hæmorrhage) is illustrated in Fig. 2, the drawing being made with a low power of the

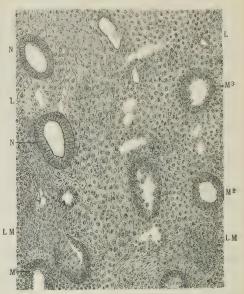

Fig. 2.—Transition of funçous endometritis into lympho-myeloma. »200. N.N. normal utricular glands in transverse section: M¹, incipient change of epithelia to myeloma: M², more advanced change of epithelia: M², epithelia completely broken up into myeloma tissue; L.L, normal lymph tissue between the utricular glands; L.M, lympho-myeloma.

microscope. In this specimen it will be observed that there is no augmentation in number of the utricular glands; many show moderate widening of their caliber; some of the utricular glands have an entirely normal lining of columnar ciliated epithelia, the wreath being unbroken all around. Other utricular glands are made conspicuous by an augmentation in number of the nuclei of the epithelia, which epithelia also become coarsely granular in their appearance. In still other cases the epithelia have disappeared, and are replaced by globular protoplasmic bodies, still retaining the breadth of the epithelial wreath. In a further advanced stage the continuity of the epithelial wreath is lost, and the gland appears to be lined with globular bodies, varying greatly in size and shape without any regularity. In the most advanced stages of the epithelial changes even the lumen of the gland may appear obstructed and filled with globular bodies, only a vestige of the previous epithelia being recognizable. In all the stages just described both the epithelia and their derivations readily take up the ammoniacal carmin stain, thus affording an easy means of recognizing even the epithelial wreaths, which are here far advanced in the process of destruction. The image, even with so low a power as two hundred amplifications, is so plain and so distinctly marked that it will suffice to immediately suggest the conclusion

<sup>\*</sup> The Differential Diagnosis between Fungous Endometritis and Tumors of the Mucosa of the Uterus, Amer. Jour. of Obst. and Discases of Women and Children,

that a grave disease is threatening the patient, requiring the most energetic surgical treatment for its cure.

Medium powers of the microscope will more readily demonstrate these changes occurring in the epithelia. (See Fig. 3.)

I have in this figure selected for illustration the earliest visible changes in the epithelia. These changes consist in an increase in the refraction of the nuclei, most of which appear almost homogeneous and of a highly glossy appearance.

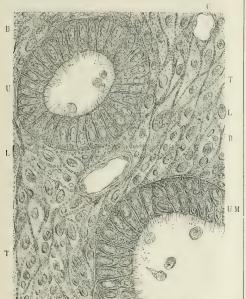

Fig. 3.—Incipient change of epithelia of utricular glands to myeloma. \*#40 U, a utricular gland in transverse section, the epithelia coarsely granular, with enlarged, almost homogeneous nuclei; UM, beginning division of epithelia into myeloma corpuscles; TT, protoplasmic and fibrous trabeculæ of myxomatous lymph tissue; L L, lymph corpuscles in the meshes of the lymph tissue; C, a capillary blood-vessel in transverse section.

Their structure is permeated with vacuoles or is coarsely reticulated. The protoplasm of the epithelia is likewise coarsely granular and densely reticulated. I admit here that if we were unable to discover other changes than those just described we would not be justified in making a positive diagnosis of myeloma; it is only the next stage that enables us to establish fully a diagnosis—i, e., the breaking up of the epithelia into oblong or globular bodies, such as are represented in the segment of the utricular gland, drawn in the lower portion of the figure we are now describing. Both the size and the gloss of the nuclei here appear increased, and at the same time a splitting up of the epithelia into segments has taken place, each segment being possessed of a nucleus. Such an image as we have just described is never seen in normal utricular glands, and when once recognized it enables us to diagnose with certainty a proliferation due to an incipient malignant growth.

The lymph tissue is augmented in this instance only in comparatively small patches. It is noteworthy that in many instances these changes in the epithelia precede those in the lymph tissue; in fact, the lymph corpuscles are in this case so slightly augmented in number and size that we may safely exclude fungous endometritis from our diagnosis and say that here a fairly normal mucosa begins to become affected by a malignant growth (incipient myeloma). The epithelia, though changed in appearance, still remain ciliated; and here also in the caliber of the utricular glands we notice, aside from a varying amount of coagulated albumin, finely granular corpuscles of different sizes and shapes, which are nothing but mucous corpuscles, such as we meet with even in normal utricular glands.

The case just described was Dr. Mundé's, the subsequent history of which I have not been able to obtain. The next specimen is that taken from Dr. McDonald's case and is certainly further advanced in malignancy than that of Dr. Mundé's. (See Fig. 4.)

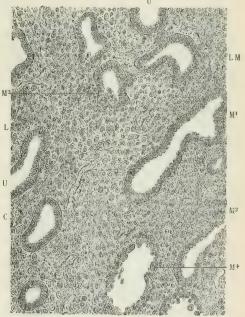

Fig. 4.—Lympho-adenoma changing to lympho-myeloma. \$200. U.U. newly formed utricular glands lined with epithelia not much changed; M., a utricular gland with incipient changes; M., a utricular gland with more advanced changes; M., partial transformation of epithelia into myeloma elements, the latter penetrating the caliber; M., complete transformation of epithelia into myeloma elements; L. lymph tissue; L.M. lympho-myeloma tissue; C.C., capillary blood-vessels.

Here we notice a considerable increase in the size and the number of the utricular glands, their caliber being tortuous, a portion being either narrowed or dilated; we further notice that there are comparatively few utricular glands with unbroken epithelia, and even these are conspicuous because of their large-sized columnar epithelia.

They are therefore in the condition termed hyperplastic. The epithelia lining most of the utricular glands we notice have become coarsely granular, and here and there we see them beginning to break up into smaller protoplasmic bodies. Of special interest in this figure is the tranverse section of the utricular gland marked M3. The lower segment of the epithelial wreath is completely lost and replaced by globular bodies which penetrate into the caliber and cause an irregular appearance of the latter. In the most advanced stage of the epithelial changes the columnar form of the epithelia is but exceptionally seen within the epithelial wreaths, most of the epithelia being transformed into globular or irregularly shaped protoplasmic bodies. The lymph corpuscles are everywhere numerous and of more than medium size, having increased in number and size to such an extent that the diagnosis of lympho-adenoma can readily be established, it being the forerunner of changes toward malignancy.

That this in reality is the case can be proved by higher powers of the microscope. (See Fig. 5.)

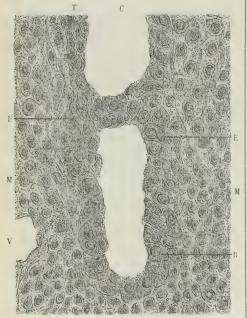

Fig. 5. Transformation of epithelia of utricular glands into mycloma corpuscles. ×600. E.E., still recognizable columnar epithelia of a utricular gland. B, beginning changes toward the formation of mycloma; T, accomplished transformation of epithelia to mycloma corpuscles; C, caliber of a utricular gland; M M, globo mycloma; V, a wide capillary bloodvessey.

This figure illustrates an oblique section of a utricular gland, which, being tortuous, shows a sæptum through its caliber which is nothing but a segment of the wall of the epithelial lining cut obliquely. In the wreath forming the wall of the utricular gland there are but a few columnar epithelia, and these are destitute of cilia. The vast majority are transformed either into multinuclear protoplas-

mic bodies or are broken up into protoplasmic lumps, each of which holds at least one nucleus or quite frequently two nuclei. These protoplasmic bodies are coarsely granular and have in some instances split up into still smaller bodies, not surpassing in size those met with in the adjacent lymph tissue. In the latter we meet with corpuscles greatly varying in size. The smallest are homogeneous, apparently devoid of structure. Somewhat larger corpuscles exhibit vacuoles in their interior, and the largest are nucleated and of a reticular structure. Even to an experienced microscopist it would be impossible to establish the nature of the interstitial tissue and to distinguish between a benignlymph tissue and that of a malignant lympho-myeloma (formerly known as small round-celled sarcoma), whereas the epithelial changes enable us to establish positively the presence of the latter-viz., lympho-myeloma.

The extirpated uterus in this case was examined and a mass of lympho-myeloma found at the fundus uteri which was fully two inches in diameter; it invaded mainly the mucosa and only to a slight extent the subjacent muscles.

The third case of my observation is that of one of my own patients. The woman was about forty years of age, having been curetted by me on account of persistent metrorrhagia, and the shreds of curetted tissue, when examined microscopically, showed conclusively the existence of incipient myeloma. Having thus established by the microscope the exact diagnosis, I immediately performed vaginal hysterectomy. This was over a year ago, and the woman ever since has been in perfect health. The image with low powers of the microscope closely resembled that of the second case just described; hence I have abstained from making another drawing.

The next drawing made with a higher power of the microscope is taken from the excised uterus near the cul-de-sac of a utricular gland, being that portion which is imbedded in the muscle coat of the uterus. (See Fig. 6.)

Here it will be observed that the changes in the columnar ciliated epithelium of the utricular gland are similar to those which have been described in the previous cases, The most noticeable feature to be observed here is that the surrounding smooth muscle tissue is in the process of transformation into lympho-myeloma, a certain proof of the malignant nature of the disease. We see some of the spindles of the smooth muscle fibers supplied with two nuclei instead of the one rod-like nucleus present in a normal condition; further on the spindle divides into halves, and finally is completely broken up into small globular or oblong bodies, such as we consider typical of lympho-myeloma, or small round celled sarcoma. The invasion of the malignant disease has just begun in the muscle layers; this early stage affords the most favorable chance for operation and for the complete recovery of the patient.

In a fourth case, which is now under my observation, the microscope revealed in the scrapings of curetted tissue a combination of globo-myeloma with lympho-myeloma, or, according to Virchow's nomenclature, a combination of large round-celled with small-celled sarcoma. The changes in the columnar epithelia of the utricular glands are the same whether the infiltration in the interstitial tissue be made up of large or of small myeloma elements.

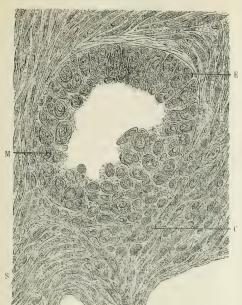

Fig. 6, "The breaking up of columnar epithelia of a atticular gland and adjacent smooth muscle-fibers into mycloma tissue," v600. E, columnar efficiency of a columnar efficiency of the columnar efficiency of problems of public stated on the columnar efficiency of the columnary of the columna

Maintaining, as I do, that a direct transition occurs of epithelia into myeloma tissue, I am aware of the probability of some objections on the part of most modern pathologists who consider epithelium to be a derivation of the epiblast and mesoblast, and a tissue of a typical character, which they do not admit can be transformed into connective tissue, the latter being derived solely from the mesoblast. Myeloma (or sarcoma) is nowadays admitted to be a strictly connective tissue growth ever since Virchow, thirty five years ago, established its histological nature. The objection advanced is a merely theoretical one, and must prove futile in the face of the fact that in other interstitial inflammations occurring in glandular organs the epithelium has been proved to perish by being transformed into fibrous connective tissue. This change has been demonstrated in chronic hepatitis, chronic nephritis, chronic orchitis and epididymitis, and pulmonary cirrhosis. A transformation of epithelial tissue into myeloma occurring in the Falloppian tube has likewise been demonstrated. I am thoroughly convinced of the possibility of such a change, and I am supported in this assertion by no less an authority than Professor Rabl, of Prague, who has shown that all tissues of the organism, including connective tissue, are derived from original epithelia, and also their products-the ovum and the spermatozooid.

My observations have proved, moreover, the correctness

of the assertion "that the epithelia of the utricular glands are transformed into myeloma elements" at the beginning of this malignant disease. This is readily recognized under the microscope, and its early diagnosis enables the surgeon to save the patient's life by vaginal hysterectomy or extirpation. Otherwise the myeloma will rapidly spread beyond the limits of the mucosa, involving fatally other structures. In a paper published.during the present year Dr. Mary A. Dixon Jones has fully demonstrated the curability of malignant growths in the early stage of the disease.\*

# A PECULIAR CASE OF FOREIGN BODY IN THE RECTUM.

By T. W. JENKINS, M.D., RESIDENT SURGEON, ALBANY HOSPITAL, ALBANY, M.Y.

Mr. J. M., aged thirty-three years, single, native of the United States, by occupation a farmer, presented himself at the Albany Hospital, Albany, N. Y., on March 1, 1894, giving the following history: While walking along the railroad between Melrose and Schaghticoke, he was attacked by four tramps and robbed of \$12. Mr. M., having some loose change, threw it into the snow to prevent the tramps obtaining all he had. Whereupon the tramps became enraged, knocked him down, and forced a turnip and a potato up his rectum. This prevented Mr. M. from following the tramps, as he had to apply for immediate relief. He consulted his family physician, who, after some ineffectual attempts at removing the articles, advised him to go to some hospital, when he immediately came to the Albany Hospital. Digital examination revealed a foreign body about four inches from the anus. A speculum was introduced and the body could be readily seen. A volsella torceps was inserted into it and it was brought down to the sphincter, which contracted so strongly that it prevented its being withdrawn. The patient was then etherized and two fingers were inserted into the rectum and alongside the foreign body, abdominal pressure being used to prevent the body slipping farther up the rectum. By these means it was brought down to the anus, and, after three volsella forceps had been fastened into it, it was withdrawn. The arrangement of the turnip and potato was unique, and a description of it will not, I trust, be amiss. The large end of the turnip was hollowed out and a hole bored through the root. A hole was also bored through the potato, and a stout string passed through it and through the turnip. The potato was thus pulled down into the turnip and the string cut off short. The dimensions of the bulk were ten inches and a half in its bipolar circumference and it was eight inches round. It had been introduced large end first. The patient was put to bed for the night, and went away quite comfortable in the morning.

March 4, 1894.

The University of Pennsylvania.—It is announced that Dr. William Pepper has resigned the office of provost, which he has held for many years to the incalculable advantage of the University, and that he has made a donation of \$50,000 to the institution. It is stated that he will retain his professorship of medicine.

# NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by D. Appleton & Co.

Edited by FRANK P. FOSTER, M. D

NEW YORK, SATURDAY, APRIL 28, 1894.

THE USE OF ORGANIC EXTRACTS AND JUICES IN THE TREATMENT OF DISEASE.

In the April number of the Dublin Journal of Medical Science Dr. James Little gives the ulterior history of a case of myxædema treated with thyreoid juice. The patient was an unmarried woman, thirty-four years old, who first consulted him on December 11, 1890. In the autumn of 1886 she had noticed that she had difficulty in kneeling; then her ankles had become stiff, and that when she walked they became swollen. When the author first saw her, she presented the typical symptoms and signs of myxædema. Her family noticed that she was taciturn and indisposed to exertion, and she herself said that she felt stupid. Her entire body had become enlarged, her neck was full, and her abdomen was so prominent that the author was asked to examine her in bed, as her mother could not believe that the patient was not suffering from a tumor. Her face seemed swollen and had at once a pale and a livid look. Her fingers had become clumsy, and she felt the cold excessively; occasionally she was hoarse. Her tongue was large and pale, her appetite was good, but she often felt distended after taking food, and her bowels were constipated. Her menstruation was excessive, and in the intervals she suffered from leucorrhœa. Her pulse was 68, and the cardiac sounds were short and sharp. There was no hum in the veins of the neck or in the pulmonary area. Neither she nor her family had noticed any change in her condition for the preceding two years.

The author advised the lady to take Turkish baths, and prescribed tincture of jaborandi, in half-drachm doses, three times a day. Eighteen months afterward, in July, 1892, she seemed a little better. She was less stupid and her face was less swollen, but there was no material change. In November she still thought herself a little better, but members of her family thought that in this she was deceived. On December 4th the first injection of thyreoid juice was given, and its administration was continued until January 9th. Altogether she had twenty-six injections; at first two each week, afterward three a week. Except on one occasion, when two syringefuls of the fluid were injected, there never was the slightest local heat or feverish disturbance, and generally the patient got up and went about as usual in the course of an hour. After the first few injections, in which there had been difficulty in pinching up the skin, it was found that this was changed-the skin could be pinched up with ease, and the alteration in the patient's whole appearance was very striking; she took part in conversation as she had not done for years, and felt lively and active. Her joints had become so supple that she could again use the needle

with neatness; she was no longer unnaturally sensitive to cold, her hands and feet were warm, and her breath was free from fætor. Her face corresponded entirely to a photograph taken before she had lost her health, and she told the author that certain black horny masses which had existed on her knees had disappeared during the treatment, also that on her head and the nape of her neck, where her hair had become thin and poor, a new growth was appearing. She was then advised to take a Turkish bath twice a week, with thorough rubbing, and to take strychnine twice a day. In the beginning of March, however, just two months after the use of the injection had been discontinued, it was noticed by the patient's family that some of her symptoms were reappearing; her face had become a little dry, pale, and puffy, and her voice a little hoarse, she felt shaky about the knees, her lower lip turned out when she spoke, and the fullness of her abdomen, which had almost disappeared, was again noticeable. She was now advised to take a preparation of the thyreoid gland by the mouth, and she had continued to do so up to the time that Dr. Little made his report, before the Section in Medicine of the Royal Academy of Medicine in Ireland, on March 2, 1894. The family butcher supplied her with fresh thyreoid glands. Every week she used two glands -half a one, for example, on Monday and the other half on Tuesday, and again half a one on Thursday and the other half on Friday. She chopped up half a gland, removed the fat and capsule from it, moistened the residue in a spoon, and swallowed it after her breakfast. She also took strychnine. At the time the author made his report she was looking and feeling in every way as well as before the myxædema had begun.

In the February number of the Australian Medical Journal there is a report of a meeting of the Medical Society of Victoria at which Dr. W. Atkinson Wood showed a patient with locomotor ataxia whom he had been treating with injections of testicle juice for five months. He thought the patient had shown notable improvement. In the discussion Dr. Grant said that the marvelous results of thyreoid feeding and thyreoid injections in myxædema and sporadic cretinism naturally made one hesitate to set arbitrary bounds to the possible powers of organic extracts in the cure of disease, but it seemed fairly safe to take the most skeptical position in regard to the cure and arrest of such a disease as locomotor ataxia with the extract of an organ so apparently irrelevant as the testicle. The obvious implication, he said, if the analogy with the case of the thyreoid was to hold good, would be that the nutrition of the spinal cord, and especially of its posterior columns, was in some way specially dependent on the presence in the blood of some secretion of the testicle, and, to complete the analogy, it would be necessary to find some plausible evidence that the disease was primarily due to a suspension of this function of the tes-Such an analogy, if it could be established, would further imply that removal of the testicle ought to be followed by the occurrence of what might then be called "tabes testipriva," just as removal of the thyreoid produced cachexia strumipriva. If such a relationship existed, surely the innumerable cases of castration, both in men and in the domestic animals, should have occasioned a sufficient number of ataxies to draw attention to the point. The speaker feared that, so far as locomotor ataxia was concerned, the Brown-Séquard injections must be placed among other therapeutic measures which operated simply by suggestion.

In the British Medical Journal for April 14th there is an account of two cases of lupus, each involving terrible disfigurement of the face, in which very decided improvement followed thyreoid feeding. The treatment was carried out under the supervision of Dr. Byrom Bramwell, of the Edinburgh Royal Infirmary. Dr. Bramwell explains that a remarkable improvement in the nutrition of the skin which the remedy produced in the first case of myxœdema in which he used it gave him the idea that it might prove beneficial in some skin diseases. He tried it in psoriasis, and in the first case there was rapid and decided benefit. He then suggested that thyreoid feeding might be of service in ichthyosis, exfoliative dermatitis, and some other skin diseases. Now, on the strength of what it has accomplished in these two cases of actively spreading lupus, he speaks of the possibility of its being useful in internal tuberculosis, in leprosy, and even in cancer.

In an editorial article in the same number of the British Medical Journal the remark is made that the remedial effects of thyreoid feeding can not be wholly explained on the theory that it supplies to the system something that it is the function of the thyreoid gland to elaborate, unless, indeed, we assume its function to be far more diversified than there has hitherto been any warrant for our supposing; and the suggestion is put forth that the gland may act as a veritable drug. This notion seems to us to be supported by its occasional depressing action on the heart and the fatal effects that have ensued in some instances.

Surely, to use Dr. Grant's expression, the thyreoid gland is quite as "irrelevant" to the various trophoneuroses of the skin as the testicle is to locomotor ataxia. It is evident that we know very little about the methodus medendi of animal extracts and juices.

#### MINOR PARAGRAPHS.

DR. BROWN-SÉQUARD'S AMERICAN JOURNAL.

In our last issue we called attention to an erroneous statement made by the British Medical Journal to the effect that during the late Professor Brown-Séquard's residence in New York he established a journal with a French name. We now learn from an esteemed correspondent that we also were in error in stating that the name of the journal was the Archives of Medicine. It seems that the name was the Archives of Scientific and Practical Medicine. The Archives of Medicine was subsequently founded by Dr. Edward C. Seguin, who had been associated with Dr. Brown-Séquard in the conduct of the journal with the ampler title.

#### ACQUA DI PERUGIA.

This once dreaded poison is generally supposed to have been very similar to the acqua Tofana of ghastly memory, but the author of a series of articles on Famous Poisoners in Fiction, now running through the English periodical called the Hospital, states that it is said to have been prepared by killing a pig, dis-

jointing it, and preparing it as for cooking, only using arsenic instead of salt. The juice or gravy from a pig thus treated is, he adds, far more poisonous than arsenic in its ordinary forms, but he gives no reason why it should be.

#### A PROPOSAL TO VIVISECT CRIMINALS.

THERE would be no occasion for us to comment upon such a proposal, which was the gist of a paper recently read before a medical society, had the matter not found its way into the newspapers. There is danger from this occurrence that a portion of the public may infer that the move is sanctioned if not supported by the medical profession. This we do not believe to be the case. At any rate, the proposal is abhorrent to us.

#### DULCIN.

The German journal of nursing (Zeitschrift für Krankenpflege) says that this new sweetening product is two hundred
times as sweet as sugar, but it warns its readers against its use,
eiting Aldehoff's experiments on animals, in which grave symptoms of poisoning were observed.

#### ITEMS, ETC.

The Methodist Episcopal Hospital of Philadelphia.—An examination for two resident physicians will be held on Thursday, May 3d, at 7.30 p.m., at the hospital, Broad and Wolf Streets. One of the ófficers thus selected will go on duty on August 1st and serve twelve months. The other will go on duty on September 1st and serve thirteen months. In accordance with the charter of the hospital applicants must have the degree of bachelor of arts in addition to that of doctor of medicine. Further information may be obtained from Dr. John B. Roberts, chairman of the committee on examinations, 1627 Walnut Street, Philadelphia.

The New York Neurological Society.—At the meeting of April 3d officers for the ensuing year were elected as follows: President, Dr. E. D. Fisher; vice-presidents, Dr. C. A. Herter and Dr. W. M. Leszynsky; secretary, Dr. Frederick Peterson; corresponding secretary, Dr. Mary Putnam Jacobi; treasurer, Dr. Græme M. Hammond.

The Alumni Association of the New York Hospital had its annual dinner at the Marlborough Hotel on Monday even ing, the 23d inst.

The Alumni Association of the Bellevue Hospital Medical College will have its annual dinner at the Windsor Hotel on Tuesday evening, May 1st.

The Brooklyn Naval Hospital.—It is announced, but not authoritatively, that this hospital is soon to be greatly enlarged and modernized, and it is said to be the surgeon general's conviction that he will be able to make it one of the finest naval hospitals in the world.

Changes of Address.—Dr. Mary E. Hennessy, to No. 20 East Twenty-ninth Street; Dr. II. Illoway, from Cincinnati to No. 1138 Madison Δvenue, New York; Dr. Albert H. Buck, to No. 14 East Forty-fifth Street; Dr. Robert Lewis, Jr., to No. 14 East Forty-fifth Street.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 15 to April 21, 1894:

Jarvis, Nathan S., Captain and Assistant Surgeon, will be relieved from duty at David's Island, New York, upon the arrival of Robinson, Samuel Q., Captain and Assistant Surgeon, and will report in person to the commanding officer, Willett's Point, New York, for duty, relieving Kendall, William P., Captain and Assistant Surgeon. Captain Kendall, upon being so relieved, will report in person for duty at Fort Columbus, New York.

SMITH, ALLEN M., First Lieutenant and Assistant Surgeon, will be relieved from duty at Fort Custer, Montana, at the expiration of his present leave of absence, and will report in person to the commanding officer, Fort Reno, Oklahoma Territory, for duty at that post.

Kennedy, James M., First Lieutenant and Assistant Surgeon, is relieved from duty at Fort Riley, Kansas, and ordered to Fort Custer, Montana, for duty.

Chapin, Alonzo R., Captain and Assistant Surgeon, will, by direction of the President, report in person to the President of the Army Retiring Board at Fort Bliss, Texas, for examination by the board.

RAFFERTY, OGDEN, Captain and Assistant Surgeon. The leave of absence granted is extended eighteen days.

WILLOOX, CHARLES, First Lieutenant and Assistant Surgeon, is relieved from temporary duty at Angel Island, California, and will rejoin his proper station The Presidio of San Francisco, Cal.

Promotion.

Merrill, James C., Captain and Assistant Surgeon, to be surgeon with the rank of major, March 13, 1894, vice Bartholf, retired from active service.

#### Society Meetings for the Coming Week:

Tuesday, May 1st: Association of Military Surgeons of the United States (first day—Washington); New York Neurological Society; New Yor Obstetrical Society (private); Buffalo Medical and Surgical Association; Elmira, N. Y., Academy of Medicine; Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson, N. J. (annual—Jersey City), and Mercer, N. J. (annual), County Medical Association (annual); Connecticut River Valley Medical Association (Bellows Falls, Vt.); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

Wednesday, May 2d: Association of Military Surgeons of the United States (second day); Harlem Medical Association of the City of New York; Society of the Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (Stapleton), N. Y.; Penobscot, Me., County Medical Society (Bangor); Essex, Mass., North District Medical Society (annual—Havenhill); Plymouth, Mass., District Medical Society (annual); Bridgeport, Conn, Medical Association.

#### THE TREATMENT OF SMALL-POX.

AURORA, ILL., April 19, 1894.

To the Editor of the New York Medical Journal:

SIR: I have just finished the reading of Dr. Welch's statistical report on small-pox. The results to the unvaccinated there shown are so terrific that any suggestion which bids fair to lessen the fearful mortality might well receive careful consideration.

The question in my mind is, Can small-pox be aborted? My experience has been very limited, and consequently may not amount to much; but, such as it is, I give it with the hope that others of wider opportunities may put it to a more extended test.

Somewhat over a year ago I treated three cases, all in children, the oldest aged eight years, the second, six years, and the third an infant of seven or eight months, at the breast. They were all perfectly regular in their development. They were discrete; the pocks on the face and lower third of the forearms and hands of the oldest, and of the babe, stood as close as they could, and a few were confluent. At their height they were globular with an inflammatory margin. They all aborted when about to pass into the stage of pustulation, the vesicles drying up, forming light scabs which dropped off in a few days without leaving any scars.

In the first, the oldest, the disease was unmodified, the two others I had vaccinated, and they had well-developed vesicles—the babe three—when the small-pox eruption came out. The vaccination had apparently no effect on the primary fever or on the eruption. In only one, the oldest, was there any reaction of maturation, and that involving a rise of temperature of only about one degree for one day. The whole course was less than two weeks in each case.

Being without experience, the treatment was entirely theoretical or empirical. It consisted of cream-of-tartar water as a diuretic; a grain or two of acetanilide or mixed cinchona salts every fourth hour, and a quarter to half a grain of sulphide of calcium every fourth hour, internally. Externally, carbolate-of-camphor ointment, on a mask to the face, on a bandage to the arms and legs, and by inunction to the body. This ointment consisted of a mixture of one part of crystallized carbolic acid and three parts of camphor with from three to five parts of vascline.

The ointment relieved the itching at once, and made the patients comfortable.

The virtue, if there was any, in the treatment was due, in my opinion, to the sulphide of calcium and to the ointment, both of which exercise a powerful influence in preventing the formation of pus.

THOMAS A. ELDER, M. D.

## Proceedings of Societies.

NEW YORK NEUROLOGICAL SOCIETY.

Meeting of Tuesday, April 3, 1894.

The President, Dr. M. Allen Starr, in the Chair.

Amyotrophic Lateral Sclerosis.—Dr. Charles H. Brown presented a boy, aged fifteen, who two years and a half befor

had begun to notice first a loss of proper speech and difficulty in whistling and in moving the tongue. These symptoms had rapidly been followed by difficulty in deglutition, closing of the eyes, deafness, and inability to move the facial muscles. After a few weeks he had been unable to use the fingers freely in buttoning and unbuttoning his clothing. At present the patient was extremely emaciated. There was paralysis of the seventh nerve on each side, also the "tapir" mouth. There was trophic degeneration in the muscles of the face and neck. The tongue was very much atrophied. The larynx was distorted. He presented all the symptoms of nuclear implication of the bulb and there was glosso-labio-laryngeal paralysis. There was atrophy of numerous muscles in the upper extremity and of a few in the lower extremity. There were general fine and coarse fibrillary twitchings all over the body, with exaggeration of the superficial and deep reflexes and slight tonic and spastic action in the movement of many muscles.

Progressive Muscular Dystrophy.—Dr. Alfred Wiener presented a man aged twenty years. He had been in good health up to May, 1893, when he had begun to suffer considerable pain in the region of the liver and spleen. This was most severe on walking. Soon afterward he had begun to experience difficulty in going up-stairs, and had noticed that he was growing very much thinner. His weakness had at first been confined to the muscles about the thigh; from here it had spread up along the back and involved the muscles of the neck and shoulders. There had been no vesical or rectal trouble. There was no history of alcoholism or syphilis.

The patient's present condition was as follows: There were no mental symptoms. The voice and speech appeared to be normal. He was very much emaciated, especially in the neighborhood of the shoulders, back, and thighs. He assumed the position of one with a marked lordosis, and walked with a waddling gait. On lying down, it was impossible for him to turn over or lift his head from the pillow. His muscles were soft and flabby to the touch. There were no contractures or fibrillary twitchings, and there were no vaso-motor or trophic disturbances. The thoracic and abdominal organs appeared to be in perfect condition. There was present no pseudo-hypertrophy in any of the lower muscles, and the patient did not give a history of any having existed. The deep reflexes were all much diminished. The nerves were not painful to pressure, and there was no special tenderness. The lordosis was due to the paresis of the muscles of the back.

Dr. Joseph Collins said that the case presented by Dr. Brown was very similar to one under his observation at the present time, except that his patient was a man, thirty-four years old, in whom the symptoms had come on rapidly about six months before. It was very uncommon to see the disease at such an early age as that of Dr. Brown's patient, but he thought that cases showing the occurrence of the disease at even a tenderer age had been recorded. The involvement of the fifth nerve that Dr. Brown's patient seemed to present he had never before heard of. The case of the patient presented by Dr. Wiener seemed to be a typical one of muscular dystrophy, and one in which the pathognomonic symptoms were in marked contrast to the case of amyotrophic lateral sclerosis shown by Dr. Brown

The President said that the contrast between the cases shown by Dr. Brown and Dr. Wiener was interesting; one presented the typical features of amyotrophic lateral sclerosis—namely, atrophy, fibrillary twitchings, increased reflexes, and bulbar invasion; the other showed a pure dystrophy, without twitching and without marked change of reflexes.

Dr. E. D. FISHER said the cases presented by Dr. Brown

and Dr. Wiener represented two distinct classes of diseases. The first showed apparently a rare condition in which an inflammation had affected the bulb and subsequently the anterior horns in the cervical region, with involvement of the lateral columns. In other words, there was amyotrophic lateral selerosis with bulbar symptoms. The usual and not uncommon order of sequence was that of involvement of the cord, with subsequent extension to the medulla. The speaker said that a patient recently under his observation, aged twenty, had presented bulbar symptoms of rather acute onset, and death had resulted suddenly, probably from some involvement of the respiratory center in the medulla. The autopsy had revealed softening in the region of the glossopharyngeal and pneumogastric neuclei. That case would probably have presented a similar clinical history if the patient had lived.

Dr. B. Sachs said he agreed to the diagnosis of amyotrophic lateral sclerosis in Dr. Brown's case. Dr. Wiener's case had undoubtedly been one of progressive muscular dystrophy.

Dr. William M. Leszynsky called attention to the fact that in Dr. Wiener's case the upper part of the trapezius muscle was atrophied, while the lower part had escaped. This partial atrophy, he said, usually occurred in progressive muscular atrophy of spinal origin.

Dr. Sachs said that the partial atrophy of muscles might also occur in spinal dystrophies.

The President said that in three cases of amyotrophic lateral sclerosis that had come under his observation the bulbar symptoms had been very prominent.

Dr. Sachs expressed the opinion that the bulbar symptoms in amyotrophic lateral sclerosis were due to a natural extension of the disease upward. He inquired whether there had been any involvement of the eye in these cases.

Dr. Brown said there might be ophthalmoplegia.

Dr. Landon Carter Gray said he had seen the eye involved

Dr. Brown said he had presented his case as a typical one of amoutrophic lateral sclerosis, but rare in the fact that it had begun in the bulb and extended downward. He thought this type of nuclear trophic and motor disorder was somewhat acute in its manifestations and ran its course rapidly. He considered that his case was in statu quo, and would progress no further, so far as degeneration of muscles was concerned. The boy presented a typical picture of a glosso-labio-larypgeal paralysis, which was an extremely rare condition in childhood. The fibrillary twitchings, the slight spastic actions, and the increase of the reflexes undoubtedly contributed to the picture of a lateral sclerosis.

The President exhibited a diagram showing the areas of annesthesia in the arms as the result of lesions involving different segments of the cervical and dorsal portions of the spinal cord. This diagram, he said, was the result of a careful study of a large number of cases in which the spinal cord had been involved. The result seemed to show that for each segment of the cord there was an area of the skin which became anæsthetic when that segment was involved.

A Critical Review of the Various Theories of Uræmia, based upon Original Experimental Observations.—Dr. C. A. Herrer read a paper with this title. He began by stating that few subjects of a medical nature had received more attention at the hand of clinicians and investigators than uræmia. Yet at the present time there was an uncertainty as to the nature of the uræmic state that was discouraging both to the student of pathology and to the practitioner who sought to understand the conditions he was called upon to treat.

Dr. Herter first gave a brief historical sketch of the growth of opinion regarding the nature of uraemia, and then reviewed in detail the various theories that had been advanced. The first one taken up was that known as the mechanical theory of uramia, which had its chief basis in the clinical and post-mortem studies of Traube, who had been impressed with the facts that in many cases of Bright's disease the blood was impoverished in its corpuscular and proteid elements, the left ventricle was hypertrophied, and the arterial tension was greatly increased. The hydramia, combined with high arterial tension, was supposed to account for the cerebral ædema found at autopsy. The uræmic symptoms Traube referred, not to cerebral ædema, but to the anæmia of the brain resulting from the pressure exerted by this ædema. There were objections to this theory. In the first place, edema of the brain was present in only a small proportion of cases where there had been unequivocal symptoms of uramia during life. There had been many cases of kidney disease with no hydræmia, no cardiac hypertrophy, and no increase of arterial tension; yet even when these latter conditions were present, there was usually no ædema of the brain. In the second place, ædema of the brain was found in conditions where Bright's disease was absent, and there were no symptoms of uramia. Then again, drugs which produced convulsions might produce cerebral ædema, and it was likely that the œdema of the brain seen in uræmics was often the consequence rather than the cause of the convulsions. A further objection to the mechanical theory was that lowering of the arterial tension, where it was high, did not necessarily relieve the uræmic symptoms. The dyspnæa of Bright's disease was often thus relieved, but usually the convulsions were not. Bleeding frequently stopped the latter, but it checked them often also where there was no excess of tension. The effects of bleeding could not be used as an argument in favor of Traube's theory, because it might be alleged that the bleeding relieved the circulation of poisonous substances.

The carbonate-of-ammonium theory had been advanced by Frerichs, and was based upon the following propositions:

- 1. It was a well-known property of urea to be readily transformed under favorable circumstances into ammonium carbo-
- 2. Carbonate of ammonium could always be detected by chemical means in the blood of uramic patients,
- 3. The injection of ammonium carbonate into the blood of animals gave rise to the symptoms of uramia.

The fate of Frerichs's theory hung on his second proposition -namely, that the blood of uramics always contained ammonium carbonate. From numerous experiments made by Gobee, Oppler, Zalewsky, and others, including the author, the following conclusions might be drawn: 1. That no ammonium carbonate, or only a small amount, was found in the blood of uræmic persons. 2. That amounts of ammonium carbonate far smaller than the quantity required to kill were readily detected. 3. That area injected into the blood of dogs was not converted into ammonium carbonate. We might therefore state that Frerichs's second proposition was without substantial foundation. It had been stated that the ammoniacal breath occasionally met with in uramic patients was evidence of ammonia in the blood. It was more likely to be found in uramics with gastro-intestinal symptoms, and the ammonia probably came not from the blood, but from the gastro-intestinal tract.

The theory of Trietz differed from that of Frerichs mainly in that it supposed the conversion of urea into ammonium carbonate to take place in the intestine instead of the blood. He held that it was by the entrance of the ammonium carbonate

into the blood that the uramic state arose, and the objections already made to the proposition of Frerichs, that uramic blood contained ammonium carbonate, applied here with equal force.

The potassium theory of Felz and Ritter was based upon the idea that the potassium of the blood-serum, which was normally present in very small amount, might accumulate under pathological conditions and cause death, the potassium salt being rapidly fatal in animals when injected into the veins in even inconsiderable quantity. The experimental and chemical evidence of various observers was strongly opposed to this theory, and it might be unhesitatingly abandoned.

The theory of Brown-Séquard was that the kidney elaborated an internal secretion which was essential to health, and the suppression of which was responsible in a large degree for the phenomena of uræmia, while the accumulation of toxic substances in the blood was thought to have little or no influence in causing uramic symptoms. The following were the chief facts upon which this hypothesis rested: 1. It was maintained that the injection of kidney extract into the circulation of a nephrectomized dog caused the temporary disappearance of uræmic symptoms. 2. It was held that the well-authenticated cases of survival of patients with anuria for a week or more without any signs of uræmia, especially in cases of mechanical obstruction of the ureters, was evidence that it was owing to the internal secretion of the kidney that this inhibition of uræmic symptoms took place. All the statements advanced in support of the first proposition, Dr. Herter said, were equivocal, and those advanced to support the internal secretion theory were equally weak.

The extractive theory of uramia referred the toxamic symptoms to the accumulation in the blood of the extractives usually found in urine; among these might be mentioned xanthine, uric acid, creatinine, etc. In order to show that a substance played a part in the production of uramic symptoms it was necessary to prove that this substance was present in the blood in uramia, or was present in excessive amount, and that the substance was toxic to the higher mammals. The evidence was not fully satisfactory regarding either of these points. The observations that had been made hardly established the fact that an accumulation of the extractives was a feature of all or many cases of uramia. The evidence was even less strong in regard to particular members of the extractive group.

Regarding the view which attributed the uramic phenomena to the action of toxines, the poisonous basic products of bacterial activity, there was little to be said, for the evidence on which it was built was scanty and conflicting. None of the toxic ptomaines that had been suspected in this connection had been found in the blood of uramics.

The evidence relating to urea as a factor in uramia might be grouped in answer to the following queries: 1. Does urea occur in excess in the blood of uramic patients? 2. Is urea toxic, and, if so, to what extent does it explain the symptoms of uræmia? As regards the first question, we had a sufficiently large accumulation of observations made by competent investigators to enable us to reach a definite decision. In the blood of Bright's disease the quantity of urea was largely increased beyond that found in the normal blood, and its presence was readily detected even by imperfect chemical methods. When we came to the second question we found that the facts which favored and those which opposed the idea that urea was toxic seemed to be about evenly balanced. Dr. Herter then reviewed the observations that had been made bearing on this question, and detailed a number of experiments made by himself which went to prove that pure urea injected into the blood of the dog and monkey in large amount was in the highest degree toxic. The autopsies in these cases had disclosed marked congestion of the gastro-intestinal tract. To what extent and under what conditions urea was a factor in uramins the author said it was not possible for him to state at the present time. Facts at our command strongly favored the view that the gastro-intestinal symptoms of uramins were due to urea. There was no doubt that we at present grouped together under the term uramin conditions which were totally distinct as regarded pathology. The evidence was very strong, though not quite conclusive, that one group of symptoms depended largely on the accumulation of urea and perhaps extractives in the blood, while another set of symptoms bore the stamp of an infective process operating in the presence of renal insufficiency. Observations might show that even further subdivisions of cases were required by pathological considerations.

It was upon the following facts that the author based the view that urea played an important part in causing the gastrointestinal symptoms of uramia:

- The presence of urea in excess in the blood in such cases.
   The property which pure urea possessed of causing such
- The property which pure urea possessed of causing such symptoms when injected into the circulation.
- 3. The occurrence in Bright's disease of congestion of the gastro-intestinal tract and the occurrence of a similar congestion in animals, which was positively due to the injection of urea into the blood.
- The fact that urea was found in the dejecta of patients with gastro intestinal uræmia.
- 5. The absence in many of these cases of any elevation in temperature or other evidence of acute toxemia.
- 6. The fact that the urine in these cases, even at the time of the crisis, was no more toxic than normal urine, which was in sharp contrast to the very toxic urines found in acute febrile uremias of cerebral type.

Dr. W. H. Thomson said the subject of uramia had always been and still remained a very confused one in his mind. Dr. Herter's paper was certainly a very valuable contribution to the subject. The cases of uræmia to which Dr. Herter had principally confined himself-those in which the characteristic symptoms were vomiting and purging-formed comparatively a small minority of those that came under observation. In many cases there were no gastro-intestinal symptoms whatever. Theoretically, Dr. Thomson said, he still felt strongly inclined to the view that toxines played a very important part in the production of the purely nervous symptoms of uræmia. Regarding the experiments performed by Dr. Herter in order to prove the toxic effects of urea, Dr. Thomson inquired whether the injection into the blood of sodium chloride or other similar substances might not give rise to derangements of the system to some degree resembling those produced by the repeated and rapid introduction of increasing quantities of pure urea.

Dr. William H. Flint said he was fully in accord with the statements made by Dr. Herter, in so far as they went to prove the ætiology of certain forms of uræmia.

Dr. J. S. ELy referred to the intestinal lesions that he had observed in performing autopsies on persons who had died of nephritis. It was often difficult to state positively whether the congestion had been present before death or had been produced by putrefactive changes. Unless the autopsy was made very soon after death, it would be bazardous to argue from the redder appearance of the mucous membrane that the congestion was the result of the disease.

Dr. Sachs expressed the hope that the critics of the future would deal more leniently with Dr. Herter's theory than he had dealt with the theories reviewed in his paper, and that they would expend the same amount of thought and labor to

prove their assertions. He did not think that any one should attempt to establish a single theory to explain such a complex of symptoms as that of uræmia. Very much the same symptoms occurred under other conditions, and we were perfectly willing to recognize that different morbid processes gave rise to them.

Dr. Herrer stated that in his paper he had not advocated any one theory to explain all the phenomena of uramia. What he had advocated was that there was a certain class of symptoms, a limited class-namely, the gastro-intestinal symptoms -which were met with in certain cases of uramia, and which were due, in all probability, to urea. The proof of this was not absolutely satisfactory, but he did not see how the proofs adduced by his experiments could be interpreted in any other light. In reply to Dr. Thomson's question, Dr. Herter said that large quantities of sodium chloride could be injected into the blood without producing symptoms comparable to those produced by the introduction of urea. As regarded the cerebral symptoms of uramia, he did not know what they were due to, and in his paper he had made no attempt to throw any light on those cases. The autopsies on the animals which had been killed by the introduction of urea had been performed immediately after death, and the intestinal congestion had been very marked.

### Book Notices.

Étude clinique de la cardio-sclérose (cardiopathies artérielles, artério-sclérose du cœur). Par HENRI HUCHARD, Président d'honneur de la Société médico-chirurgicale de Paris, Médecin de l'hôpital Bichat. Paris: Félix Alcan, 1893. Pp. 139.

The author has insisted for a long time past upon the clinical importance of considering the influence of the heart upon the prognosis of diseases in general. In many cases an asystolic condition will suddenly manifest itself, as in old age, and fatally terminate what would have otherwise appeared a trivial indisposition. These apparently sudden cardiac implications are peculiar to a sclerotic condition of the arterial system, a condition whose symptoms have for the first time been clearly defined by Huchard. These symptoms are in the beginning such as would be generated by excessive arterial tension, and are, for instance, local algidities, similar in nature to a local syncope of the extremities, and rheumatoid pains or cramps in the continuity of the extremities, accompanied by a sensation of local fatigue or of paretic heaviness, due to a spasmodic condition of the arterio-capillary system (Weber). Vertigo is frequent and may be either matutinal or habitual. Cephalalgia exists; the head is heavy and the ears ring. Visual trouble may take on the form of ophthalmic megrim. The patient is somnolent, his head feels empty, and he is unfit for intellectual work.

There exists a tendency to congestion and to hæmorrhage. Polyuria is frequent, even bubitual, and is alternating in character, the urine being sometimes abundant and limpid and at other times concentrated and charged with urates.

Paroxysmal pallor of the face occurs, and a rapidly produced anæmic condition may as quickly give place to the normal color or even to a congested state.

The pulse is full, strong, and vibrating if the excess of tension is due to an active vaso-dilatation, or constricted, tense, stretched like an iron wire, if it is consecutive to a vaso-constriction. This latter condition may be so accentuated as to give rise to an error in diagnosis which it will require the aid of the sphygmomanometer to rectify. The needle of this in-

strument (Potain's) will mark twenty, twenty-five, or thirty divisions instead of the normal figure of sixteen or eighteen. The pulse is usually regular in the beginning of the disease, without inequality or intermittence. In confirmed arteriosclerosis this condition changes, and, moreover, the right and left pulse may be unequally manifest, the left one being the weaker of the two.

The essentially pathognomonic sign of excessive arterial tension is, however, a diastolic modification in intensity and tonality of the aortic bruit, usually located in the second right intercostal space and resembling the sound formed by the rebound of a hammer from a solid surface. Of fundamental importance to the diagnosis is the existence of an abnormal pulsation of the arteries, and more particularly of the cervical, of an increased aortic dullness, and of elevation of the subclavian arteries. The last two symptoms are due to aortic dilatation, which latter gives rise also to a functional aortic insufficiency.

 The size of the heart may be increased by myo-hypertrophy and sclero-hypertrophy, and thus its area of dullness and the location of its apex beat may vary indefinitely according to these abnormal conditions.

The precordial shock will be more forcible and accentuated as a result of the excessive tension, to which are also due a more or less persistent tachycardia and painful palpitations, frequently nocturnal. The systole is prolonged, and the sphygmograph demonstrates the existence of arrhythmia and intermittence, either of a temporary or of a definite character.

Acute dilatation of the heart is of frequent occurrence, accompanied by a partial mitral insufficiency. Asystolism may ensue from this dilatation.

The arterio-sclerosis of the viscera produces claudication of their various functions. This is due to the intermittent blood supply and was inexplicable before Huchard's studies threw a light upon the whole subject (Grasset). This meiopragia is the cause of the sudden, frequently recurring, and mobile pulmonary congestions, of the acute pulmonary cedemas, and of that form of dyspaces sine materia which is accompanied by paroxysmal coughing without expectoration, dependent probably upon acrtic or cardiac irritation (François Frank). The spirometric capacity is diminished.

The nutrition suffers, the renal elimination is faulty, the urotoxic coefficient is lowered, and the patient becomes self-intoxicating, dyspnœic, vertiginous, and delirious.

For the diagnosis, the pathological anatomy, and the treatment we beg to refer the reader to the author's very valuable clinical study.

The one fault of this most original work is perhaps the frequency with which the author renews his examination of each symptom, entailing the necessity of continual reference to preceding paragraphs in order to appreciate the relation of the various aspects of the question.

The Dispensatory of the United States of America. By Dr. George B. Wood and Dr. Franklin Bache. Seventeenth Edition. Thoroughly revised and largely rewritten. With Illustrations. By H. C. Wood, M. D., LL. D., Professor of Materia Medica, etc., in the University of Pennsylvania, etc.; Joseph P. Reminston, Ph. M., F. C. S., Professor of Theory and Practice of Pharmacy in the Philadelphia College of Pharmacy, etc., and Samuel P. Sadler, Ph. D., F. C. S., Professor of Chemistry in the Philadelphia College of Pharmacy. Philadelphia: J. B. Lippincott Company, 1894. Pp. xliv-1950.

The newest edition of this venerable work—always a favorite with the American medical and pharmaceutical professions —shows abundant marks of thorough revision, especially in the increased number of articles in the second part, the first section of which is devoted to the National Formulary. The text is preceded by a useful Index of Diseases. The reputation of the book is well maintained in this edition.

Congenital Affections of the Heart. By George Carpenter, M. D., London. Member of the Royal College of Physicians, etc. London: John Bale & Sons, 1894. Pp. 103. [Price-3x, 6d.]

The brief reference that is made in text-books to congenital cardiac affections is the author's reason for publishing this brochure.

He briefly reviews the embryonic development of the heart, and then considers the congenital affections of the pulmonary artery and its orifice, which Peacock's study showed to exist in a hundred and nineteen cases out of a hundred and eighty-one of various congenital cardiac affections. Reference is made to the rare formation of sæpta in the cardiac cavities and to the equally rare condition in which the ductus arteriosus supplies or gives origin to the descending aorta. Coarctation of the aorta, the origin of the pulmonary artery from the left ventricle, transposition of the aorta and pulmonary artery, and failure of the sæptum of the bulbus arteriosus to develop, are briefly mentioned. Perforate sæptum ventriculorum, patent foramen ovale, and patent ductus arteriosus are mentioned at greater length, and the author agrees with other observers that these conditions may exist without presenting physical symptoms of cardiac abnormity. Regarding valvular abnormities, the author quotes Osler and Viti to the effect that diminution of the number of segments of the semilunar valves is usually found in the aorta, while redundancy in the number of segments usually occurs, according to Dilg's statistics, in the pulmonary artery.

The actiology of these affections is obscure; they may be due to feetal endocarditis or to developmental errors.

The symptoms are various, even cyanosis being absent inconditions in which its presence might have been expected from the character of the lesion. The stethoscopic signs are of a varied character, and often examination reveals nothing unusual.

Dr. Carpenter has not endeavored to make this a monograph with an exhaustive study of collected reports of congenital cardiopathies, but rather a brief exposition of what is known regarding these diseases. In doing this he has, perhaps, subordinated his personal experience to too great an extent, but not to the sacrifice of an intelligent consideration of the subject.

Notes on Nursing in Eye Diseases. By C. S. Jeaffreson, M. D., F. R. C. S. E., Senior Surgeon and Honorary House Governor to the Northumberland, Durbam, and Newcastle Infirmary for Diseases of the Eye, etc. Bristol: John Wright & Co., 1894. Pp. vi-90. [Price, 2s. 6d.]

Dr. Jeaffreson states, to begin with, that he has "no hesitation in saying that many eyes are annually sacrificed in this country [England] through inefficient and careless, or rather, I would say, ignorant nursing." This is certainly unfortunate if true, but it is to be feared that still more unfortunate results might follow were the directions given in this book to be carried out in every particular. Cases in sufficient numbers present themselves at any large clinic with evil effects produced by the application of poultices to the eyes to warn a practitioner not to follow the advice given on page 25, and the nurse who follows that advice will not be apt to recommend herself there-

by very highly to either physician or patient. Again, to apply a cooling lotion it is recommended that "four folds of lint be soaked in it, then applied to the eyes and secured by a light muslin bandage, the lotion being renewed every hour." This would seem a rather efficient method of applying a warm poultice for from fifty-five to fifty-nine minutes every hour, with short intermissions during which a cooling lotion is applied. The work is not worth so long a notice as this, and the pieces of advice cited will serve to show its character.

Syllabns of the Obstetrical Lectures in the Medical Department of the University of Pennsylvania. By Richard C. Norris, A. M., M. D., Demonstrator of Obstetrics, University of Pennsylvania, etc. Third Edition. Philadelphia: W. B. Saunders, 1894. Pp. xviii-222. [Price, \$2.]

In the present edition of this little work the author includes those additions to his lectures that have been made during the past two years. In all points we notice that his instruction is abreast of recent investigation, and the terse presentation of the various topics can not fail to impress the student and enable him to grasp the subject.

A Manual of Therapeutics. By A. A. Stevens, A. M., M. D., Lecturer on Terminology and Instructor in Physical Diagnosis in the University of Pennsylvania, etc. Philadelphia W. B. Saunders, 1894. Pp. 17 to 435. [Price, \$2.25.]

The medical student of the present day regards the study of materia medica and therapeutics as his most difficult task. We know this because he has told us so, and our own past experience does not lead us to doubt him. It is but natural that this should be so, for the study of drugs, doses, and treatment offers no opportunity for the play of logic as other branches of medicine do, and therapeutics is not susceptible of practical demonstration in the medical courses of to-day. This branch of medicine is, then, to the student dry and dogmatic to the last degree.

Since the science of therapeutics must, however, be learned, it is necessary to make its study as easy as possible. With this idea in mind, many authors have produced "handbooks," "manuals," and "quiz compends," which, as the subject offers no chance for other handling, consist of tabulations, condensations, and (we dislike to record it) questions and answers. Now, most of these books are very bad.

The manual which Dr. Stevens has written is far superior to most of its class; in fact, it is very good. It is not a book to which the practitioner would turn for information (though he might do worse), as the author himself says, "this manual has been prepared especially for students." To students we are sure the book will be a great help, for it is very well arranged, and the classification, heading, paragraphing, and condensation, always so important to the student, are unusually good. Moreover, the book is reliable and accurate. Practically it is divided into two parts, of which the first deals with materia medica—that is, drugs—and the other with applied therapeutics. To the volume are added indices of remedies and of diseases, as well as a table of doses.

Clinical Diagnosis. By Albert Abrams, M. D. (Heidelberg), Professor of Pathology, Cooper Medical College, San Francisco, etc. Third Edition, revised and enlarged. Illustrated. New York: E. B. Treat, 1894. Pp. xi-273. [Price, \$2.75.]

Gonorrhea. Being the Translation of Blennorrhea of the Sexual Organs and its Complications. By Dr. Ernest Finger,

Docent at the University of Vienna. Third Revised and Enlarged Edition. With Seven Full page Plates in Colors and Thirty-six Wood Engravings in the Text. New York: William Wood & Company, 1894. Pp. vii-824. [Price, \$3.]

The International Medical Annual and Practitioner's Index: A Work of Reference for Medical Practitioners. By Various Authors. Twelfth Year. New York: E. B. Treat, 1894. [Price, \$2.75.]

Transactions of the Southern Surgical and Gynæcological Association. Volume VI. Sixth Session, held at New Orleans, La., November 14, 15, and 16, 1893.

The Operative Treatment of Non-microcephalic Idiocy. By J. F. Binnie, C. M., Kansas City. [Reprinted from the *Annals of Surgery*.]

The Twenty-first Annual Report of the Metropolitan Throat Hospital for the Treatment of the Nose, Throat, and Ear.

Transactions of the American Dermatological Association at its Seventeenth Annual Meeting held at the Hotel Pfister, Milwaukee, Wis., on the 5th and 6th of September, 1893.

### Miscellany.

Contagion and Phthisis Pulmonalis.—Under this heading the brilliant author of the Asolopiad, Sir Benjamin Ward Richardson, M. D., F. R. S., says in the current number of that periodical:

"As if to discount good influences of a true hygienic character in reducing the death-rate from phthisis pulmonalis, some enthusiasts, in writing on the contagion speculation, have endeavored to show that the lessened mortality from the disease, observable during the past few years, is due to the influence of the doctrine of contagion. Dr. Lawrence Flick, of Philadelphia, has written in this strain in the Medical News for May 14, 1892. He calculates that the actual decrease of deaths from phthisis in Philadelphia, from 1881 to 1891, is 0.734 per thousand of living people, which, with the present population, shows a saving of 784 lives a year. The result he assumes to be due to the circumstance that members of the medical profession in Philadelphia, having become converted to the hypothesis that phthisis pulmonalis is spread by contagion from particles of dried sputum derived from patients affected with the disease, have taken care that such contagious matter shall be at once destroyed, and so have prevented the spread of the disease by communication. It is astounding how speculations of the kind named are supported on coincidences. There is a physician living in this country who, with equal argument, believes that the reduced mortality from the disease in question is due to a medicinal cure for the disease which he himself has introduced. To prove the beliefs of such advocates, it would have to be demonstrated how many practitioners have prescribed the means of prevention or cure specified, and how many times their suggestions have been practically acted upon. Impossible demonstrations! As to the first—the conversion of the profession to the hypothesis of contagion and the influence of that conversion in modifying the death-rate—it is the simplest truth to say that if the profession in Philadelphia is at all like the profession here, there is not a shadow of evidence in support of the proposition. There are a few probably who, accepting the hypothesis out and out, are more particular respecting cleanliness and removal of expectoration than they were; while the many, looking at the hypothesis doubtfully, are as little influenced by it now as they ever were. Why should this not bo

so? The experience gathered in Naples on this subject, when the most rigid rules for destruction of all morbid material failed to render service, is not likely to be forgotten; while the majority of observers have never been able to see the evidence that would establish the hypothesis. Let me take in illustration my own experience. In my student life I was under an able teacher of the practice of medicine-the late Dr. Andrew Anderson, of Glasgow. In his lectures on phthisis, he entered carefully into the contagion theory, at that date-1846-rather popular. He held a wise reserve on his own part; but he told us the question was a vexed one, and he urged us all to watch most carefully for ourselves in our future lives. I was one who determined to watch intently, without bias-how could I have any occasion for bias?-and persistently. I have sustained my watchfulness in the same spirit from then until this day-i. e., over a period of nearly fifty years. Every opportunity has been afforded me for watching. I entered early in life into the experience of a large general practice; I left that for physician's practice in London. I became physician to an infirmary for diseases of the chest, situated in a densely populated part of London. I held my post for about fourteen years, rising to the senior physicianship. During a part of this same period I acted as one of the physicians to the Metropolitan Dispensary, the Blenheim Street Dispensary, and the Margaret Street Dispensary, another institution for the treatment of consumption. This was a wide field for practice and for observation. Moreover, at these institutions, where I gave systematic instruction, I was fortunate in having able assistants, who kept careful notes of the cases under treatment. In the course of the period named no fewer than three thousand patients suffering from phthisis came before me; and during all the time the question of evidence on the point of contagion was never for a moment lost sight of. It is the fact that in all this field of practice not a single particle of evidence ever came before me that sustained the contagion theory, or gave, on reliable data, the least color to it. No professional brother, no assistant, no nurse, no person connected in any way with the phthisical sick, ever afforded indication of having received the disease by communication; and it is worthy of remark that no physician of my acquaintance, in the days I speak of, ever expressed a suspicion of communication by contagion. In the fifties, we had in London a society for the special study of chest diseases. In it were men of acute observation, and of skill in diagnosis. We were all engaged in hospital practice, and we all worked earnestly. The late Dr. Baly, Dr. Snow, Dr. Leared, Dr. Sibson, Dr. Francis Webb, Dr. Risdon Bennett, Dr. Edward Smith were members of this society, as were Sir Richard Quain, Dr. Hawksley, Dr. Cockle, and one or two more whose names escape me. We met in turn in each other's homes; we drafted patients to our meetings for careful study; we discussed every point with the utmost freedom of discussion; but I feel sure at that time not one of us entertained seriously the hypothesis of contagion, Was it that we were all blind to evidence which must have been passing every day before our eyes-evidence which should have occurred to us, apart from any hypothesis, if it existed? Was this revived hypothesis wanted to open our eyes? Or was it that when the hypothesis was once restarted those who accepted if did not really see what they had failed to see previously, but were led to adapt their discernment to the requirement and to receive what was necessary to be received in order that the hypothesis might stand on a logical foundation?

"I resigned my work as physician to the special institution for diseases of the chest toward the latter part of 1867, but I have remained up to the present time profiting from another course of experience in a practice of twenty-five years. In the tter part of that time much controversy has been revived on

this subject of the communicability of phthisis by contagion, and although I have taken little public part in the controversy, I have been as active in observation as ever I was, endeavoring to learn without the least prejudice the exact facts. For many years I have sat at a board of insurance directors, feeling all the responsibility that attaches to that official duty. In every case of phthisis pulmonalis that has come under my notice in practice, and in every case of the same disease of which I have had cognizance otherwise, I have been vigilant to arrive at the circumstances under which the first symptoms of the disease were manifested. Not once has there been evidence of origin of phthisis from contagion on which I could rely. It is true I may more than once have heard the conclusion that some contagious influence was at work, but on further inquiry the evidence has broken down. There were living near to me two sufferers from the malady who occupied the same house. They were brother and sister, the only children of a professional friend; they had the hereditary history painfully characteristic of phthisis, and in the course of the affection in them from the beginning to the fatal end their symptoms ran so closely as to be like twin phenomena. Could there have been contagion in these cases? Many might have said so who had not taken pains to investigate the facts. To me the facts were familiar. The brother was often assisting me in my work, so that I knew his history; and his attack dated from a severe cold contracted by exposure to an intense chill at an evening party, to which he went lightly clad, and in which he added to the risk from changing portions of his dress for some much lighter ones in order to take part in a charade or play. He sent for me at once when he became ill. It was the old story of pneumonia followed by rapid tubercular phthisis. The sister at this time was many miles in the country, where she had been for several months, during which time the two had not once met each other. She, like her brother, took a severe cold, and when she came home and passed under my care she was in the same state of phthisis as he. In neither case was there the remotest evidence of contagion, yet because of their affinity I afterward heard it adduced that contagion was at work. Not infrequently on being called upon to prescribe for phthisical patients the statement has in late times been made to me that the disease had been contracted by contagion, but in not one instance has any proof been supplied that would in a court of law of the first instance bear investigation.

"I ask naturally in conclusion, Can I be blind to open facts, or do I see correctly, and has the hypothesis of contagion blinded those who see differently from myself? Willingly I will admit myself blind, and will submit myself to any correction that will give me sight; but the correction must be supplied, and in a form that makes all so clear that he who runs may read. I must be shown one case of phthisis in which the evidence is absolute that the disease was contracted from contagion, and that it could not possibly have been produced by any other determining cause.

"Returning to Dr. Flick and his argument—that the mortality from consumption in Philadelphia, or any other city for the matter of that, is reduced by the precautions taken in regard to the disposal of the sputum of afflicted persons—the point is clear enough that what he traces as cause and effect is due to nothing more than coincidence.

"No sanitarian for the past forty years, to my knowledge, has doubted the fact that phthisis pulmonalis will disappear just in proportion as broad sanitary views are established and brought into practice. We have all believed and, as we think, proved that under new conditions, in which there is provision for a better heredity, in which cleanliness becomes the watchword of sanitation, in which the youth of both sexes can enjoy free

exercise and recreation in the open air, and in which the labor of life in confined places is being reduced to a proper standard; we have all believed that with these changes the disease would die out altogether. In my Essay on the Hygienic Treatment of Pulmonary Consumption, published in 1856, these principles were so strenuously enforced that I was looked upon in entorcing them as a visionary, and as wanting in that practical acumen which was necessary for successful effort in the treatment and prevention of disease. I was not alone in that argument, but I was one of a very few. In time our principles prevailed, and the reduction of mortality from consumption in military barracks, owing to reforms which were insisted upon in our teaching, afforded direct evidence, long before this contagious idea was advanced, of the truth and correctness of our observation.

"The process of purification has since then gone on by leaps and bounds, and we are beginning to see the good results; a new hypothesis springs up coincidently which may or may not be right to a certain extent within its own narrow range, but which has no more to do with the great results at this time boasted of than the reduction of typhus in its worst forms has to do with carrying of camphor in the pocket, or placing rue in the wardrobe or on the desk before the judge of assize. It may be quite practical, it is quite practical, to take care that the expectorated secretion of consumptive patients is destroyed. The late Dr. William Farr put his finger on this fact, and every sanitarian felt the importance of his advice. But this is merely a matter of cleanliness, merely a part of the whole system of perfect hygiene; and if we let this one thing stand as if it were the whole thing, we shall merely lead to carelessness in regard to everything else, and shall make matters worse instead of better. Dr. Flick is so good an observer and so earnest a man, there can be no hesitation in being critical on this particular part of his instructions, and it is only because it is painful to see him parrowing himself to one issue that this criticism is ventured upon. I hope he will take a wider view as time rolls on, and accepting the old message of the Mishna, that 'Outward cleanliness is inward godliness,' or, as John Wesley transformed it, 'Cleanliness is next to godliness,' will become a preacher of true catholic doctrine in all that relates to sanitation and the physical welfare of the world,"

The Extraordinary Effects of a Large Dose of Hyoscine. -In the March number of the Indian Medical Record, Assistant Surgeon Balagopal, L. M. S., relates the case of a man, fifty years old, who was an inmate of the Chhatarpur Hospital suffering from mania. For twenty-five years he had had maniacal attacks each of which lasted at least a month, after which he gradually recovered his sanity and remained quite sane for six or seven months. He had been treated by various eminent physicians, but only with the result of tempering the violence of his maniacal paroxysms; the attacks continued to occur twice a year. At last, after having been forced to retire from his work as a post-office employee, he had asked the author to treat him, remarking that life was a burden, and that he would rather poison himself than suffer any longer from his dreadful disease. Two or three days after this a severe attack of maniacal delirium occurred, and the author tried divers sorts of nervine, sedative, and antispasmodic medicines, together with the use of plasters, blisters, and setons, but all proved of no avail. As a last resort he gave the patient a hypodermic injection of a sixth of a grain of hyoscine hydrobromide. In two or three minutes after the injection the patient fell down prostrate upon the ground and cried out that he was dying. His face became deadly pale and the conjunctive insensitive. The pupils were extremely dilated, the breathing was very difficult and

stertorous, the limbs were contracted spasmodically, the pulse was very weak and compressible, and the temperature was subnormal. The author, being very much alarmed at the man's condition, hastened to his bookcase to ascertain the proper dose of the medicine, and to his utter dismay found that it was from 0.03 to 0.01 of a grain, while he had given a sixth of a grain. Feeling that he had unwittingly poisoned the poor maniac, he began to stimulate him by means of hypodermic injections of twenty minims of sulphuric ether every half hour. After the third injection the spasms were seen to diminish in frequency and in strength, and after the fourth they ceased, the conjunctivæ responded to the touch, and the breathing became a little easier. At the same time the color was seen to return to the man's face. In half an hour after the fifth injection the man tried to open his eyes and to speak; after this he improved gradually and recovered consciousness in five or six hours after he had received the dose of hyoscine. After this the patient improved day by day, and in the course of a week he was of sound mind, and had since shown no signs of cerebral trouble.

The Use of Sulphur in Surgery,-In the Lancet for April 7th Mr. W. Arbuthnot Lane, assistant surgeon to Guy's Hospital and to the Hospital for Sick Children, London, refers to a short paper published by him in the Medical Week for December 8, 1893, entitled How Far is Sulphur likely to be of Service to the Surgeon? wherein he had described two cases of very extensive tuberculous disease of the hip and elbow in which sulphur had been used with very satisfactory results, since both patients had recovered rapidly and perfectly. Mr. Lane now repeats the summarized conclusions of that paper as follows: 1. Sulphur applied locally appears to exert no deleterious effect on the health of the individual. 2. It gives rise to products which are powerfully caustic in their action; therefore it must be used in small quantities and with discretion. 3. It destroys all organisms, whether free in a space or growing in the surrounding tissues. 4. It acts much more powerfully upon recently incised structures than upon granulating surfaces. 5. Its action is rendered more uniform and general and less violent by mixing it with glycerin. 6. If used in any quantity the drug must be removed within a day or two and irrigation subsequently adopted.

Mr. Lane states that since he wrote that paper he has used sulphur very largely, not only in tuberculous conditions, but in other infective processes, and with the most satisfactory results. In the treatment of extensive tuberculous disease with much destruction of bone his rule is, if there is a well-defined cavity in the bone, to pack it with iodoform in the way described by him in the Lancet for July 15, 1893; if there is no such suitable space, and if it is impossible to remove all tuberculous material with certainty, he places an emulsion of glycerin and sulphur in the cavity, allows it to remain for twenty-four hours, and then irrigates daily for a time with a weak solution of mercury bichloride or with a sterile normal saline solution. He thinks its action is seen to the best advantage perhaps in recent foul wounds with extensive laceration and bruising. He relates a case illustrative of this. A man, thirty years old, was admitted into Guy's Hospital under his care on February 11th. While cleaning a window he had fallen forty feet. His forearm had been transfixed on a spike of the area railing and he had been suspended upon it. The skin and muscles of the forearm were found extensively lacerated along the whole of its length, and portions of the man's coat, which was very dirty, were found imbedded among the "pulped" muscles. Such portions of the muscles as were very much mashed and soiled were removed. The ulnar artery was not injured. The damage to the soft parts was so extensive and the fouling so considerable that the

author believed that, however thoroughly the parts might be washed with germicidal lotions alone, amputation would soon become necessary. Therefore, after cutting away some parts, cleaning up others, and removing the foreign matter present, he introduced everywhere into and between the lacerated tissues gauze saturated with an emulsion of sulphur and glycerin. At the end of twenty-four hours this was removed; the wound was then found to give out a decided odor of sulphureted hydrogen and the tissues were covered with a soft black slough. Irrigation with a weak bichloride-of-mercury solution was used daily, and the intervals in and between the lacerated muscles were packed with cyanide gauze. The slough soon separated, leaving a healthy granulating surface. The highest temperature recorded was 100.6° F., during the evening following the operation. The author says there is little or no doubt in his mind that such a result could not have been obtained by means of the germicides in general use.

Mr. Lane's experience is that there is no topical remedy so perfectly satisfactory in its results in cases of lupus as sulphur, whether in the form of powder, emulsion, or ointment. In every case in which he has used it a rapid cure has resulted, with practically no destruction of tissue other than the lupus tissue. In case of cancerous or sarcomatous ulceration, he says, the destruction of the soft parts can be regulated and determined very accurately. Unlike the escharotics in common use, sulphur has practically no effect on healthy cutaneous or mucous surfaces, but requires the action of a granulating raw surface to determine the formation of sulphurous and sulphuric acids, which are apparently the agents that influence the vitality of the organisms and tissues with which they come in contact. Mr. Lane has also found sulphur most useful in the foul ulcerative stomatitis which is so common among the children of the poor and so obstinately resists the local treatment usually adopted. In such cases, if gauze or wool dusted abundantly with the finely powdered drug is retained in firm contact with the foul ulcerated surface for an hour or two, sufficient destruction results to clear the surface of its infective organisms, and it then heals rapidly. Should one application not produce a sufficient result, others may be resorted to, the number depending on the extent and locality of the ulceration, the facility with which the plug can be retained in position, etc. He has found applications of sulphur equally effectual in destroying the microorganisms that produce the foul impetiginous ulcers seen in children. Sulphur, like iodoform, says Mr. Lane, becomes active as a germicide, and is very considerably more powerful in its action than iodoform, only when in immediate contact with a raw surface, the living tissue causing it to form certain combinations with hydrogen and oxygen. In this connection the author refers to Dr. Ray-Pailhade's experimental researches on philothion, a substance which that writer infers to exist in living tissue and to be capable of combining with sulphur.

The National Association of Railway Surgeons,-The seventh annual meeting will be held in Harmony Hall, Galveston, Texas, on May 8th, 9th, 10th, and 11th, under the presidency of Dr. W. J. Galbraith, in addition to whose address the programme will include the following subjects for discussion: Conservatism in the Treatment of Compound Comminuted Fractures of the Leg, by Dr. George R. Dean, of Spartanburg, S. C.; Compound Fractures, by Dr. Milton Jay, of Chicago; Plaster-of-Paris Splints to Fractures, Simple and Compound, by Dr. J. G. Buchanan, of Pittsburgh, Pa.; Anæsthesia (Local and General), and its Proper Production, by Dr. E. A. McGannon, of Brockville, Ontario, Can.; Fracture and Dislocation of the Spine, by Dr. Thomas H. Manley, of New York; Diagnosis of

ture of the Spine, by Dr. C. H. Hughes, of St. Louis; The Treatment of Injuries of the Cord and its Envelopes with and without Fracture of the Spine, by Dr. W. B. Outten, of St. Louis; The Medico-legal Relation of Injuries of the Cord and its Envelopes with and without Fracture of the Spine, by Clark Bell, Esq., of New York; Some of the Uses of Hot Water in Recent Injuries in Railway Surgery, by Dr. N. A. Drake, of Kansas City, Mo.; Minor Surgery, by Dr. J. D. Myers, of Huntington, W. Va.; Color-blindness, by Dr. D. Emmett Welsh, of Grand Rapids, Mich.; Exhibition of New Tests for Simulated Blindness in One Eye, by Dr. James L. Minor, of Memphis, Tenn.; Evisceration vs. Enucleation following Injuries of the Eye, by Dr. A. E. Prince, of Springfield, Ill.; Rectal and Anal Surgery and its Relation to Railway Injuries, by Dr. S. G. Grant, of Kansas City, Mo.; Should the National Association of Railway Surgery become a Delegatory Body? by Dr. R. Harvey Reed, of Columbus, Ohio; Quarantine and its Relation to the Railway Surgeon, and Railway Surgeons' Relation to Quarantine, by Dr. Van B. Thornton, of Hempstead, Texas; Litigation Psychosis, by Dr. Matthew D. Field, of New York; A Case that Ought to have been One of Railway Spine, and its Treatment, by Dr. C. M. Woodward, of Tecumseh, Mich.; A Novel Case of Cerebral Traumatism, by Dr. J. R. Barnett, of Neenah, Wis.; A Case of Fracture of the Spine-Operation followed by Improvement, by Dr. John E. Sylvester, of McArthur, Ohio; The Evolution of Railway Surgery, by Dr. E. R. Lewis, of Kansas City, Mo.; Dressing of the Stump in Amputation, by Dr. A. B. Brumbaugh, of Huntington, W. Va.; Railways and Railway Surgery, by Clark Bell, Esq., of New York; An Improved Railway Stretcher, by Dr. R. Ortega, of Ciudad Porfirio Diaz, Mex.; Thiersch's Grafts in Extensive Destruction of the Soft Parts about the Large Joints, by Dr. Henry W. Coe, of Portland, Ore.; A Digest of Four Hundred Consecutive Railway Cases, by Dr. Howard J. Williams, of Macon, Ga.; The Management of Burns and Scalds, with Cases, by Dr. C. K. Cole, of Helena, Mont.; A Case of Spinal Injury with Rupture of Intestine; Operation and Recovery, by Dr. I. N. Warren, of Sioux City, Iowa; Concussion, by Dr. George W. Cox, of Brownsville, Oregon; Shock: its Phenomenal Results, by Dr. Willis M. Wilson, of Curtis, Neb.; Clinical Cases: Shock, Hæmorrhage, and Tendon Suture, by Dr. John Van Duyn, of Syracuse, N. Y.; and The Treatment of Shock, by Dr. James H. Letcher, of Henderson, Ky.

American Gynæcological Society.-The nineteenth annual meeting will be held in the Columbian University, corner of Fifteenth and H Streets, Washington, on May 29th, 30th, and 31st, under the presidency of Dr. William T. Lusk, of New York in addition to whose address the programme will include the following papers and subjects for discussion: Extirpation of the Uterus in Diseases of the Annexa (to be opened in the affirmative by Dr. J. M. Baldy, of Philadelphia, followed by Dr. Florian Krug and Dr. H. T. Hanks, of New York; in the negative by Dr. T. A. Reamy, of Cincinnati, followed by Dr. W. G. Wylie, of New York); The Management of Face Presentation (to be opened by Dr. Edward R. Reynolds, of Boston, followed by Dr. Charles Jewett, of Brooklyn, and Dr. B. C. Hirst, Dr. C. P. Noble, and Dr. E. P. Davis, of Philadelphia); The Abuse of Trachelorrhaphy, by Dr. William R. Pryor, of New York; The Fatal Nausea and Vomiting of Pregnancy, by Dr. Edward P. Davis, of Philadelphia; Myomectomy as a Substitute for Hystero-myomectomy, by Dr. E. C. Dudley, of Chicago; The Proper Position of Recent Surgical Methods in the Treatment of Uterine Fibroids, by Dr. William T. Lusk, of New York; Rupture of the Uterus (to be opened by Dr. Charles M. Green, of Boston, fol-Injuries of the Cord and its Envelopes with and without Frac- lowed by Dr. Malcolm McLean and Dr. H. C. Coe, of New

York); The Alexander Operation, by Dr. Clement Cleveland, of New York; The Ultimate Results of the Treatment of Retrodisplacement by Pessaries, by Dr. Francis H. Davenport, of Boston; The Influence of Laceration of the Perinæum on the Uterus, and the Operation for its Repair, by Dr. W. Gill Wylie, of New York: Retroperitoneal and Intraligamentous Tumors of the Uterus and Annexa, by Dr. William H. Wathen, of Louisville; Inflammation of the Ureters from a Medical Standpoint, by Dr. Matthew D. Mann, of Buffalo; The Influence of Minor Forms of Tubal and Ovarian Disease in the Causation of Sterility, by Dr. Thomas A. Ashby, of Baltimore; The Results of Vaginal Fixation of the Stump in Abdominal Hysterectomy, by Dr. Henry T. Byford, of Chicago; Symphysiotomy versus the Induction of Premature Labor, by Dr. Charles P. Noble, of Philadelphia; The Conservative Surgery of the Female Pelvic Organs ("referee," Dr. William M. Polk, of New York; "co-referee," Dr. William Goodell, of Philadelphia); In Memoriam, Dr. Andrew Dunlap, by Dr. John C. Reeve, of Dayton, Ohio; and In Memoriam, Dr. John M. Keating, by Dr. Edward P. Davis, of Philadelphia.

The American Dermatological Association .- The eighteenth annual meeting will be held at the Arlington Hotel, Washington, on May 29th, 30th, 31st, and June 1st, under the presidency of Dr. R. B. Morison, of Baltimore, in addition to whose address the following papers will be presented: Thyreoid Feeding in Diseases of the Skin, by Dr. G. T. Jackson, of New York; The Rare Forms of Alopecia, by Dr. G. H. Fox, of New York; A Case of Favus of the Head and Body, by Dr. J. A. Cantrell and Dr. E. J. Stout, of Philadelphia; The Pathological Anatomy of Pearly Epithelioma of the Face, by Dr. J. A. Fordyce, of New York; The Question of the Contagiousness of Molluscum Contagiosum, by Dr. H. W. Stelwagon, of Philadelphia; The Therapeutic Value of Urea in the Treatment of Skin Diseases, by Dr. C. W. Cutler, of New York; Ichthyosis Congenita (so-called Harlequin Fœtus)-History of a Patient still Living, by Dr. S. Sherwell, of Brooklyn; Angeioma Serpiginosum and some other Dermatoses, by Dr. J. C. White, of Boston; The Protozoa-like Bodies of Herpes Zoster; a Contribution to the Study of Psorospermosis, by Dr. M. B. Hartzell, of Philadelphia; Cold as an Ætiological Factor in Diseases of the Skin, with a Report of Cases, by Dr. W. T. Corlett, of Cleveland; Acquired Idiosyncrasy for Quinine, showing Peculiar Cutaneous Manifestations, by Dr. C. W. Allen, of New York; a paper by Dr. E. B. Bronson, of New York (title to be announced); The Relation of Impetigo Herpetiformis to Pemphigus Vegetans, by Dr. J. Zeisler, of Chicago; and Notes on Drug Eruptions, by Dr. J. A. Fordyce, of New York.

Subjects for Discussion.—The Distribution and Control of Leprosy in North America: Distribution, by Dr. J. N. Hyde, of Chicago (to be discussed by Dr. J. E. Graham, of Toronto, Canada); Diagnostic Features and Treatment, by Dr. P. A. Morrow, of New York (to be discussed by Dr. A. Van Harlingen, of Philadelphia); Contagiousness, Prophylaxis, and Control, by Dr. J. C. White, of Boston (to be discussed by Dr. G. H. Fox, of New York, Dr. J. D. Bryant, of New York, and General W. C. Wyman, U. S. M. H., of Washington). Open discussion of the Clinical Forms, Ætiology, and Treatment of Dermatitis Exfoliativa.

American Pædiatric Society.—The sixth annual meeting will be held at the Arlington Hotel, Washington, on May 29th, 30th, 31st, and June 1st. The preliminary programme includes the following papers: A Eulogy on Dr. John M. Keating and Dr. Charles Warrington Earle, by Dr. F. Forcheimer, of Cincinnati; A Eulogy on Dr. T. F. Sherman, by Dr. T. M. Rotch, of Boston; The Influence of Blood Supply on the Irritability of

the Spinal Motor Centers, by Dr. B. K. Ratchford, of Newport, Ky.; The Early Diagnosis of Pott's Disease of the Spine in Children, by Dr. Dillon Brown, of New York; a case, by Dr. William P. Northrup, of New York; Tonsillotomy, followed by Diphtheria and Croup, by Dr. Augustus Caillé, of New York; The Ætiology and Prevention of Rickets-the Influence of Race (especially in Italians) and the Influence of Race in Negroes, by Dr. Irving M. Snow, of Buffalo, N. Y., and Dr. George N. Acker, of Washington; A Case of Congenital Rickets, by Dr. C. W. Townsend, of Boston; Infantile Scurvy, especially its Differential Diagnosis, by Dr. J. Henry Fruitnight, of New York; An Aid to the Sterilization of Milk in Artificial Infant Feeding, by Dr. A. Seibert, of New York; Report of the Committee on the Nomenclature of Diseases of the Gastro-enteric Tract, by Dr. T. M. Rotch, of Boston; Report of the Committee on the Nomenclature of Diseases of the Mouth; Acute Pvelitis in Infancy, by Dr. L. Emmett Holt, of New York; Infantile Myxœdema, by Dr. William P. Northrup, of New York; and the Hæmorrhagic Disease of the Newborn, by Dr. C. W. Townsend, of Boston.

Edema in the Newborn.—The April number of the Revue mensuelle des maladies de l'enfance publishes an article on this subject by M. Semet in which he remarks that edema is often wrongly confounded with selerema. The latter is nearly always fatal, but the former, although serious, may be cured. In the newborn ædema seems to occur especially in those who are weak, those who are born before the full term, and those subjected to bad hygienic conditions and cold. The principal cause seems to be a feebleness of the right heart, and an insufficiency of muscular contraction, especially on the part of the respiratory organs. Consequently thoracic aspiration can not be made with full strength, whence ensue defective haunatosis and, consecutively, obstruction of the cardiac cavities, of the blood-vessels, and chiefly of the veins.

In all cases, the newborn are not well nourished, they refuse to nurse, and cry incessantly. When ædema appears, the skin becomes pale, waxy, and hardened, and pressure with a finger leaves a very distinctive imprint. The disease can be checked and cured in a few days, or infiltration increases and the ædema becomes generalized. The parts most frequently involved are the lower limbs; rarely the upper limbs. It is more frequently developed on the posterior aspect of the leg, afterward reaching the thighs, the pubes, and the feet, and if it spreads upward, the face of the upper limbs, the cheeks, the eyelids, and finally, the back. Œdema is rarely completely generalized.

The skin, which is pale, becomes purplish-red, and cyanosed on the face and on the extremities. At the same time it becomes harder and a digital impression persists if cedema is slightly marked, but is impossible to obtain if infiltration is accentuated. In the latter case there can sometimes be observed difficulty in the movements and a rather marked hardness of the skin, but no immobilization of joints inducing rigidity of the body. The skin is cold, and the thermometer indicates the extremely low temperature of 92° and 95° F. In some cases a remarkable temperature has been observed. Henning and Letourneau speak respectively of 71° and 68°. A. Robin remarks that the axillary temperature is always equal, if not superior, to the rectal temperature.

Œdema, if it is not very extensive, may be cured; if generalized, it is often fatal. Recovery occurs after four or five days, sometimes longer. Resorption takes place little by little, the circulation and respiration are slowly restored, the body becomes warm, and recovery gradually sets in. Pulmonary and gastro-intestinal complications are frequent.

The diagnosis of ædema is generally quite easy, although

the affection is often confounded with sclerema, the nature of which is not well known. The latter is nearly always accompanied by athrepsia, and consists in a special hardening of the subcutaneous connective tissue. In the two diseases are found a certain number of similar phenomena, such as general feebleness, smallness of the pulse, which is sometimes scarcely perceptible, considerable falling of the temperature, and also, in some cases, hardening of the skin. Nevertheless, whereas in sclerema the skin can not be wrinkled, in cedema it can be pinched between the fingers, proving that there is infiltration in the subadjacent connective tissue. Sclerema attacks first the back, then the shoulders, and lastly the thighs. Œdema is more frequently found in the lower part of the abdomen, the genital organs, and the posterior face of the legs. Sclerema readily becomes generalized, and the hardness of the skin causes absolute immobility. With the exception of slight movements of the thorax, and sometimes also of the muscles of the face, the patient is in a condition which resembles cadaveric rigidity-Contraction also may exist in the lips and in the cheeks, and the rigidity of the muscles in this region may prevent suction. Nothing like this is found in œdema, and there is never seen sufficient rigidity to permit, as in sclerema, the child to be lifted bodily by any part without change of shape.

Infiltration may render the action of the joints difficult, but it never leads to tetanic rigidity. In ædema athrepsia is a rare complication, whereas it nearly always exists in sclerema.

The treatment consists especially in the employment of hygienic methods, of a tonic regimen, and of guarding against cold.

The Leucocyte's Lament.—We find the following verses in the March number of the Bristol Medico-chirurgical Journal;

The leucocyte was in a gland
With inflammation red,
He grasped a comrade by the hand
And with a sob he said:
"'Mid solitary follicles
I wend my weary way,
Deep down in crypts of Lieberkühn
Far far from light of day.
Alas! this aching nucleus
Can ne'er be free from pain,
While tissues hide my beauteous bride
I ne'er shall see again.
A rosy-red corpuscle she,

The pride of all the spleen.

Her like in this dark gland, I fear,
Will never more be seen.

A fierce bacillus captured her, And reft her from my side; Carbolic oil his plans did foil, But ah! it slew my bride.

With pseudopodia feebly bent
And bowed down nucleus, I
Must turn to pue?" And speekis

Must turn to pus."—And, speaking thus, He wandered forth to die.

Oh! lightly they'll talk of that leucocyte true As they label and mount and degrade him, But little he'll reck, when with aniline blue They've stained and in Canada laid him.

The Philadelphia County Medical Society and the American Medical Association.—At a meeting of the Philadelphia County Medical Society, held on April 18th, the following resolutions were adopted:

Whereas, The code of ethics of the American Medical Association declares it derogatory to professional character for a of the Medical Department.

physician to dispense or in any way promote the use of a secret nostrum, and the American Medical Association, by a resolution unanimously adopted at its meeting in 1892, forbade the advertising of such nostrums in its Journal; and

Whereas, The Journal of the association has continued to advertise such nostrums, and in defense of its course in this particular has published an anonymous personal attack on a member of the American Medical Δssociation and of this society:

Resolved, That the Philadelphia County Medical Society respectfully demands that the trustees of the Journal shall, in their public official acts, respect the spirit and letter of its code of ethics, and that the columns of its Journal shall not be used for the anonymous personal abuse of its members in good standing.

Resolved, That a copy of these resolutions be transmitted to the Medical Society of the State of Pennsylvania, to the American Medical Association, and to the weekly medical journals.

[Signed.] T. B. Schneideman, Secretary.

The Communication of Typhoid Fever to the Fætus.—In the Presse médicale for March 24th there is a summary of an account, published in the Münchener medicinische Wochenschrift by Dr. T. Janisewski, of a case in which a woman, who was eight months pregnant, was admitted into a hospital for typhoid fever, which was diagnosticated by a bacteriological examination of the stools. In twelve days she was delivered of a living child, but it died at the end of five days. At the post-mortem examination no lesions were found except moderate hypertrophy of the spleen. However, cultures from the lungs, the spleen, the kidneys, the intestine, and the mesenteric glands produced bacilli which had all the characteristics of Eberth's. In all respects they agreed with the culture made from liquid withdrawn by puncturing the spleen of a living person affected with typhoid fover.

Tricresol.—This substance, called in the trade "trikresol," has been made the subject of an experimental research by Dr. M. Charteris, professor of materia medica and therapeutics in the University of Glasgow, who reports in the Lancet for March 31st that the liquid is a mixture of orthocresol, metacresol, and paracresol, soluble in water in the proportion of from two to two and a half per cent. He finds that it is three times as strong as pure carbolic acid as a germicide and only a third as poisonous. Consequently, he remarks, its advantages for surgical purposes are very pronounced, and in all probability some combination of it with an alkaline base will in the future be prepared which may with safety and profit be administered internally in specific infectious diseases.

The District Medical Society of Union County, New Jersey.—At the annual meeting, held in Plainfield, on Wednesday, the 11th inst., the following officers were elected: President, Dr. Norton L. Wilson, of Elizabeth; vice-president, Dr. W. E. Cladek, of Rahway; secretary, Dr. E. B. Grier, of Elizabeth; treasurer, Dr. F. Westcott, of Scotch Plains; reporter, Dr. S. J. Keefe, of Elizabeth.

The Cleveland Medical Society.—At the second quarterly meeting, on Friday evening, June 22d, Dr. William Pepper, of Philadelphia, will deliver an address, and on the following morning he will hold a clinic in one of the Cleveland hospitals, open to the profession at large.

The Medical Department of the University of Cincinnati.—The Cincinnati College of Medicine and Surgery has been affiliated with the University of Cincinnati under the title of the Medical Department.

# LECTURES ON THE DIAGNOSIS OF ABDOMINAL TUMORS.

By WILLIAM OSLER, M. D., PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY.

LECTURE V.—TUMORS OF THE INTESTINE, OMENTUM, AND PANCREAS; MISCELLANEOUS TUMORS.

I. Tumors of the Intestine.—Cancer, the common cause of tumor, occurs most frequently (apart from the rectum) in the cæcum and the sigmoid, hepatic, and splenic flexures of the colon. Not one of the three cases which have been under observation presented a typical group of symptoms, but singly and together they illustrate many interesting features of the disease. In the first place, the affection may be latent, revealed at autopsy alone, or the early and indeed the chief symptoms may be due to the secondary tumors. The first case illustrates very well the latency of the disease. Without intestinal symptoms, for some months after he came under observation the sole objective feature was the progressive enlargement of the liver. Only six weeks before his death, after he had become greatly emaciated, we discovered a tumor in the right iliac region, and subsequently he had hæmorrhage from the bowel.

Case XLIII. Cancer of the Carum and Colon; Latent Course; Enormous Secondary Enlargement of Liver .- John R., aged twenty-nine years, admitted February 6, 1892; under observation until September 25th. The family history is good. The patient was healthy and strong until four years ago, when he had severe malaria. For eight months prior to his admission he had not been very well, and had had irregular pains in the abdomen. During the past eight months he has been pale, has felt weak, has not been able to work, and on several occasions he has been slightly jaundiced. His appetite has been good; bowels regular; has had no diarrhea. For several months past he has noticed that the upper part of the abdomen was swollen and tender to the touch. On admission, the patient was pale, but looked well nourished; no fever; pulse, 86. The lower thoracic zone is much expanded, particularly on the right side. The epigastric and hypochondriac regions bulge in a very prominent manner, and there is a rounded mass, nine centimetres in transverse extent, which extends from under the ribs on the right side. In the median line the edge is clearly defined, and reaches to within four centimetres of the navel. To the left it extends far over beyond the parasternal line, and to the right deep into the lumbar region. The percussion over this large mass is flat and continuous with the liver duliness, which begins in the median line at the base of the xiphoid, in the nipple line at the sixth cartilage, and in the axilla at the seventh. Although there was no fever and no definite history of any intestinal trouble, the patient's age and good condition seemed against the diagnosis of cancer of the liver. Accordingly, an aspirator needle was thrust in at the prominent part, but only blood obtained. Under observation the liver evidently increased in size, and there seemed to be no question that it was a new growth. The question then arose as to the primary seat of the disease. The stomach symptoms were insignificant, he had no vomiting, the appetite was good, and a test breakfast was readily disposed of. Subsequently, in August, very careful

examination of the abdomen revealed a hard mass low down in the flauk. It was usually ill-defined, but on several occasions Dr. Thayer thought that it was quite distinct. There was no diarrhœa; no special change in the fæces, which were always well formed. He remained under observation outside the hospital during the summer. The liver tumor did not increase very much in size. He became progressively weaker and very much emaciated. Two weeks before death he passed two large stools containing clots of blood. He became extremely emaciated before his death.

Autopsy.—The liver weighed seven thousand two hundred grammes; the right lobe was much disfigured, and presented numerous nodular tumors with elevated margins and depressed centers. A distinct groove marked off the anterior margin of the right lobe from the rest of the organ. On section, secondary cancerous nodules were found scattered through the entire organ. The primary growth was found to be at the head of the eæcum and the beginning of the colon, which presented an extensive fungating mass, softened and necrotic on the surface. The mesocolon was thickened and the glands much involved. Microscopically the tumor proved to be a cylindrical-celled epithelioma. Extensive secondary nodules were scattered through the lungs.

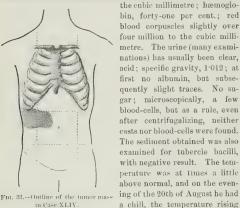

In the following, by far the most interesting and instructive case of the series, intestinal symptoms were absent throughout, and the presence of a solid, firm mass deep in the right side led us to think at first that there was a renal tumor. I give you the notes just as I dictated them from day to day, as they illustrate the erroneous diagnosis, and the gradual development of features which led to its revision.

Case XLIV. Tumor in Right Flank; Suspected to be a Renul Sarcoma; Subsequent Development of Dilatation of the Stomach and Signs of Tumor in the Bowel .- Thomas B., aged thirty-two years, admitted August 3, 1892, complaining of pains in the abdomen. There was nothing of special moment in his family history. Present illness began about eighteen months ago with griping pains in the abdomen, attacks of which occurred from time to time and were attributed to indiscretions in diet. On the voyage to this country, ten months ago, he was very seasick, and had a great deal of pain in the abdomen; and then for the first time he noticed a hardness or lump on the right side. The bowels were, as a rule, constipated. He has never passed blood in the stools or in the urine. For some months he has been gradually losing in weight, and has been getting pale and weak. When in good condition he weighs one hundred and seventy-seven pounds; he now weighs one hundred and twelve pounds.

Present Condition.—Patient is a tall, well-built man, pale, scarcely cachectic. The tongue is moist, slightly coated; pulse 104, of fair volume. The examination of the thoracic organs is negative. The abdomen is symmetrical, but looks a little fuller in the right flank. The right hypochondriac and lumbar regions are filled with a firm, somewhat irregularly rounded mass, which on bimanual palpation can be readily moved up and down. On making firm pressure with the left hand in the right renal region the mass becomes apparent beneath the skin just to the right of the navel. To the left it extends almost to the middle line; the lower border is three centimetres below the transverse navel line. Both the lower and the left borders are rounded, but toward the right, just beneath the tip of the eleventh rib, there is a distinct nodule to be felt. In its anterior part it can be separated distinctly from the liver both by

palpation and percussion, but in the anterior axillary line the tumor passes beneath the ribs, and the dullness is here continuous with that of the liver. On percussion there is resonance over the tumor mass to the left of the nipple line. The general situation of the tumor is indicated in the annexed chart. There are no glandular enlargements. The spleen is not palpable and the dullness is almost obliterated.

The patient has no sweats, no cough. There is a leucocytosis, the white corpuscles numbering over twenty thousand to

in Case XLIV

to 103.5°. On the 6th of September a medium sized aspirator needle was thrust upward and backward beneath the twelfth rib, and a little blood stained fluid removed, which contained round cells twice the size of leucocytes. The needle seemed imbedded in the firm substance. The patient objected to an exploratory operation.

The situation and shape of the tumor, the mobility, and the readiness with which it could be pushed forward by pressure from behind pointed to a renal origin. The nature of the growth was less certain. If he is correct in dating the first symptoms as far back as eighteen months the tumor has not attained the size usually reached by new growths of the kidney within this time. There has also been no blood in the urine. The single chill does not speak specially against new growth. Can it be tuberculous nephritis? The family history is good; the urine is and has been clear; there is no involvement of the epididymis, and fever has not been a marked feature. If the tumor were due to saccular dilatation following occlusion by tuberculous or calculous disease, certainly the aspirator would have withdrawn purulent fluid, and there would have been at some time pus in the urine. The rapid loss in weight points strongly in favor of new growth.

October 12th.—The patient was shown in clinic this morning. The emaciation has progressed; he has had for ten days much more fever, and a chill on the sixth in which the temperature rose to nearly 104°; on the seventh, eighth, and ninth it remained between 102° and 103°. There are no special changes in the urine. He has been at times constipated, but the stools show nothing peculiar. The tumor mass has not increased materially in size, though perhaps it reaches a little further toward the navel.

The patient says that he notices flatus bubbling in the vicinity of the tumor, and that it divides into, as he expresses it, two or three portions. The hand placed on the tumor experiences occasionally a feeling as if gas was escaping through it, and the left half is resonant; but this might be due to the presence of the colon over the mass.

This morning, with the students, the various probabilities of renal sarcoma, or tuberculosis, or calculous pyelitis were discussed. The state of the urine and the failure of aspiration to draw fluid seem opposed to the latter conditions. The chills and fever were not thought to be inconsistent with sarcoma.

The question was also discussed as to whether it really was a renal tumor, and whether it might not be associated with the liver or with the hepatic flexure of the colon. It did not seem possible, with the evidence at our disposal, to reach a definite diagnosis.

Since the above note of October 12th there have been several developments in this case.

15th.-For the past two days the patient has had a great deal of vomiting, often bringing up large quantities. Last night he vomited eight hundred cubic centimetres of brownish fluid containing half-digested food. The reaction was acid, the odor rancid, and tests for free hydrochloric acid were negative.

16th .- Ewald's test breakfast given this morning, and withdrawn fifty minutes later, gave nearly three hundred cubic centimetres of a slightly grayish, muddy fluid, containing comparatively little food matter. It was acid in reaction, odor rancid and sour, turned congo paper blue, and gave a very distinct rosy-red color with the phloroglucin-vapillin solution. Microscopically, there were fat crystals, undigested food stuffs, numerous bacilli, and yeast cells.

17th.—The vomiting has continued during the past twentyfour hours, and he does not look so well to-day. The tumor mass occupies the right hypochondriac region, extends into the right lumbar and umbilical regions, but not into the epigastric, reaching apparently to within about two centimetres of the navel. Below, it extends exactly eight centimetres from the costal margin in the nipple line. The greatest prominence is just below the point of the tenth rib. On first palpating it this morning there was at the lower margin a prominent rounded, ridge-like mass, firm and hard, which gradually disappeared, feeling as if it were a tubular, muscular structure in contraction. Again this morning gas was felt bubbling through the mass. Percussion over it gave flat tympany; slight change noted in rolling the patient over on the left side. At a second visit to-day there were noticed for the first time waves of peristalsis crossing the upper abdomen from left to right, and the outlines of the stomach could be distinctly seen, the lower border reaching to the navel. At the time of the passing of the waves the walls of the stomach became firm, and bubbles of gas could be felt passing through the tumor.

20th.—The signs of dilatation of the stomach have been for the past few days unusually distinct. He has had vomiting of large quantities of liquid. The amount of urinary secretion is very scanty. He sank gradually and died on the 20th.

Autopsy .- By Dr. Flexner. On opening the abdomen the stomach was seen to be greatly dilated, reaching considerably below the level of the navel (Fig. 35). In the right hypochondriac region a tumor mass was adherent in part to the anterior abdominal wall, just between the costal margin and the crest of the ilium. Just below the hepatic flexure of the colon there was a tumor the size of an orange completely encircling the bowel. It was seven centimetres in length and eight centimetres in circumference. The coats were uniformly infiltrated and the tissue looked infiltrated with colloid. The inner surface was ulcerated and the lumen of the bowel not here narrow. The cæcum and ascending colon were opened in situ. At the hepatic flexure the tumor mass was adherent to the right lobe of the liver and behind was attached to the kidney. The finger, introduced into the colon at this region, entered a number of pockets, one of | well nourished; no fever; tongue slightly furred. Abdomen is which directly led into the liver substance. On its posterior | full, and about six centimetres to the right of the navel there is surface and to the right the tumor was closely united to the a projection beneath the skin, uninfluenced in position by the curve of the duodenum, into which it had grown in such a respiratory movements. On palpation this is felt to corre-

Fig. 34 - Cancer of the colon; dilatation of the duodenum and stomach in Case XLIV

way as to cause a distinct narrowing. The mucous membrane before. There were no peristaltic waves. On several occasions of the duodenum was ulcerated from the central part of the tumor, but was intact elsewhere. The stomach was greatly dilated; the mucous membrane smooth. The pylorus itself and first part of the duodenum were greatly stretched; the groove between them is well seen in the figure. The finger could be passed into the duodenum, but the narrowed lumen would not more than admit the tip of the little finger. The liver showed numerous secondary nodules of cancer. The mesenteric glands were enlarged and contained metastatic nodules.

The third case presented a very prominent movable tumor which, from its general characters and situation, seemed to be connected with the bowel, though the intestinal symptoms were here also quite in the background.

Case XLV. Tumor in Right Flank; Removal of Growth in Cacum and Ascending Colon .- Sylvester H., aged sixty years, admitted October 15th, complaining of a lump in the abdomen. He has been a very healthy man. For two years past has had slight pain after eating, with nausea and constipation.

His present illness began about three months ago with troublesome constipation, and three or four days would pass without a movement from the bowels, and the faces would be hard and lumpy. He took medicine for it, since which time the bowels have been rather loose, the stools yellow and containing slime, but never blood. No tenesmus, no cramps. Five weeks ago he had an attack of vomiting, followed by a second attack a week later; brought up sour material; no blood. In the past three months he has lost a great deal in weight, and has become, he thinks, a little pale. He has been short of breath on exertion, and lately the feet have been swollen.

Present Condition .- Patient looks a little pale, but is fairly

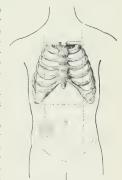

spond to a rounded nodular mass, feeling of about the size of a cricket ball, situated midway between the navel and the anterior superior spine of the ilium. It feels very superficial; is not tender; is very hard; and one or two ridges can be felt upon it. There are no changes in its consistence. On deep inspiration it descends slightly. It is freely movable and can be pushed over as far as the navel. No gas is to be felt to bubble through it. On light percussion there is a flat tympany over it.

As the patient had had very few intestinal symptoms and had had dyspepsia for several years, with recently two attacks of vomiting, the attention was naturally directed, in the first place, to the condition of the stomach. Palpation was negative in the region of the pylorus. There was no clapôtage. The organ did not appear to be dilated. The upper limit of resonance was at the fifth rib in the nipple line, and the lower limit above the navel. On October 17th the tests for free hydrochloric acid were negative. On the 21st it seemed that the stomach tympany was somewhat more extensive than

a test breakfast was given, and on October 26th the mucus withdrawn was blood-stained; no free hydrochloric acid. The tumor could be readily separated from the liver and could be moved far down into the right iliac fossa. While the symp-

toms in this case pointed rather to disease of the stomach, the situation and general character of the tumor were those of an intestinal growth. The stomach, too, seemed somewhat relaxed, and the absence of free hydrochloric acid was suggest-

On November 7th Dr. Halsted operated and found that the tumor occupied the cæcum and the commencement of the ascending colon. It was readily removed. The patient seemed to do very well, taking his nourishment and gaining in strength until the 13th, when, after an attack of nausea and coughing, Fig. 25. Situation of the tumor in the stitches gave way and about two feet and a half of the

small intestine protruded. He became very restless, gradually sank, and died the same day. The tumor was a cylindricalcelled epithelioma, involving the entire circumference of the gut. but excavated and not narrowing in any way the lumen of the gut. The autopsy showed an interesting feature-namely, the presence also of a cancer on the posterior wall of the stomach and of a second small tumor mass in the jejunum.

In the diagnosis of cancer of the intestine the following points may be taken into consideration. In comparison with the subjects of malignant disease of the stomach very many of the patients are young; thus you have noticed that Case XLIII was only twenty-nine years of age, and Case XLIV was only thirty-two. Intestinal features are present in a majority of cases, though they were by no means suggestive in the patients who have been under our observation. Griping, colicky pains are common, even without the signs of obstruction. With narrowing of the lumen of the gut very characteristic features occurattacks of severe griping pain, abdominal distention, the presence of active, sometimes visible peristalsis in the distended coils of bowel, and, if the condition persists, vomiting and all the signs of intestinal obstruction. In the case of Sylvester H., I called your attention repeatedly to the fact that the intestinal symptoms depended largely upon the state of the lumen of the bowel at the seat of the tumor. If fungous masses project and cause more or less narrowing, colicky pains and constipation are inevitable; but, on the other hand, as the tumor grows, if there is necrosis of its surface, with excavation, neither pain nor constipation may be present. Diarrhea and the passage of much slime with the fæces are not infrequent symptoms. Hæmorrhage is also common. The blood is not often in large quantities; when the tumor is in the sigmoid flexure it may be bright and very little changed, but in growths about the excum it is often much altered before it appears in the stools. There are cases in which constant loss of small quantities of blood is a very special feature, and the patient becomes profoundly anæmic. Sloughy fragments of the tumor may sometimes be passed in the fæces.

A cachexia develops progressively but with very variable rapidity. It may, however, be well marked before any features have arisen suggestive of intestinal trouble. The loss in weight may, too, be slight, even after the tumor has persisted for many months. There is at present a patient in Ward C with a tumor in the right iliac region, which has persisted for nine or ten months, and upon the nature of which very many opinions have been expressed. She is well nourished, but profoundly anæmic. It did not seem possible from the symptoms, general or local, to make a definite diagnosis, but an exploratory operation showed an extensive new growth in the cæcum. Another patient, who had repeated small hæmorrhages, developed an extreme anemia, with retention of the general fatty panniculus. When extensive secondary growths develop, as in Case XLIII, the cachexia may be profound. The tumor in cancer of the intestines may be readily and easily discoveredindeed, evident on inspection, as in Case XLV. On the other hand, as in Case XLIII, it may not be until the terminal stage of the disease that the growth is found. A small tumor of the hepatic or splenic flexure of the colon may escape repeated examinations. Mobility is a special feature of growths in the large bowel. Large tumors, however, of the cocum may be quite fixed. The most

movable growths are those connected with the sigmoid flexure. Variability in size is also a marked character, and at one examination the mass may appear as large as the closed fist or even two fists, and the next day it appears not larger than a small apple. These variations are due largely to the presence of facal masses in the vicinity. Two very important features in the intestinal tumor may sometimes be detected on careful palpation—namely, the hardening during contraction of the hypertrophied wall in the vicinity of the growth, and the bubbling of gas through the tumor, which may be heard as well as felt. This latter feature drew our attention to the possibility of the tumor in Case XLIV being associated with the colon. The intestinal symptoms above referred to and a progressive cachexia are generally sufficient to warrant a diagnosis.

II. OMENTAL TUMORS.—In two cases a rolled, thickened omentum formed a definite tumor in the upper portion of the abdomen. I will not enter into full details, but just mention the cases in abstract.

Case XLVI. Pleuro-peritoneal Tuberculosis; Ridge-like Tumor in the Epigastric Region .- A man, aged thirty years. admitted May 9, 1893, with ascites. In October he had had shortness of breath with swelling of the legs and abdomen. He improved gradually, but the ascites has persisted and on admission there were signs also of effusion in the right pleura. In the abdomen there was an ill-defined resistance, a hand's breadth in width, at the junction of the umbilical and epigastric regions; below it terminated in a well-defined, hard border, which could be very easily felt, and was indeed at first thought to be the edge of the liver. On percussion there was a flat tympany above the hard transverse ridge. There was in this region also a very well marked peritoneal friction rub. The history of the case, the involvement of pleura and peritonæum, and the existence of this transversely placed tumor mass in the upper abdominal zone led to the diagnosis of tuberculosis. Dr. Finney made an exploratory operation and drained the peritonæum. The omentum was rolled up, thickened, and attached to the transverse colon. The patient did well and was discharged from the hospital greatly improved.

Case XLVII. Chronic Proliferative Peritonitis; Thickened Omentum .- In this patient the tumor was more interesting and unusual, though I must say no diagnosis was made. I refer to it especially because I have been talking to you so much in the ward class about chronic proliferative peritonitis in connection with the case of the little girl with a visibly pulsating liver. Without going into unnecessary details, the patient, aged about fifty-five years, was admitted with suppurative cellulitis of the left leg which had come on in connection with an ascites of some weeks' duration. His condition was very serious, and one for which we could not do very much. He gradually sank, and died ten days after admission. The abdomen was persistently distended, and we never arrived at a definite opinion as to the cause of the dropsy. The parietal peritonæum was adherent to the anterior surface of the colon and to the omentum for a distance of 3.5 centimetres. The omentum was represented by a thick fold, seven centimetres in vertical by nineteen centimetres in transverse extent, the upper part of which was converted into a white, shining, leathery-like structure, not, however, rolled or curled upon itself. Similar thickenings were present over the anterior surface of the colon. The intestines, particularly the loops of small bowel, were bound together by dense adhesions, separated with the greatest difficulty, and there were patches of thickening on the mesentery. There was

a condition of chronic perisplenitis and perihepatitis. There was a thrombus in the portal vein.

As in the chronic tuberculous peritonitis, this simple proliferative form may pucker the omentum into a definite tumor, lying athwart the upper zone of the abdomen. Encapsulated exudate may also form tumor-like masses. More frequently, however, the recurring ascites simulates cirrhosis of the liver. In one way the proliferative peritonitis may produce a very extraordinary tumor, of which I have reported an example.\* So great may be the thickening of the mesentery that the whole bowel is shortened, and the coils of intestine matted together may form a mass the size of a cocoanut firmly bound to the spine.

III. Tumors of the Pancreas.—Two cases of disease of this organ came before me for diagnosis—one a cancer, the other possibly a cyst.

The cancer case you will remember, as I demonstrated the specimens after a ward class early in the session, reasonable probability may sometimes be reached in the diagnosis. The following may be mentioned as suggestive points: Rapid emaciation with early, intense, and persistent jaundice; dilatation of the gall bladder, fatty stools, glycosuria, salivation, and the presence of a tumor between the umbilicus and ensiform cartilage. Nausea and vomiting, though often present, are variable features. Beginning usually in the head of the pancreas, the growth early compresses the common duct and causes obstructive jaundice. A persistent, intense icterus may also result from compression of the duct in the gastro-hepatic omentum by infiltrated glands, secondary to cancer of the stomach, to invasion of the ducts themselves by cancer, and by stenosis of the common duct, rarely by gallstones without any complication. The emaciation is rapid, and stress is laid by some writers upon an excessive cachexia. There may be very little pain throughout the illness; in some cases, however, attacks of colic occur. A dilated soft gall bladder, while not in itself of special import, is often suggestive, taken in connection with other features. In the primary cancer of the bile passages, which also causes an early and intense icterus, the gall bladder, if enlarged, is more often hard and firm. Disturbance of the function of the organ may be manifest by (1) the presence of fat in the stools (even a definite stearrhea), which is not a constant symptom, but of value when present; (2) by glycosuria, which is also not constant. Salivation is sometimes present, and Dr. Lainé, of Media, has called my attention to several cases in which this symptom was present, and in which the diagnosis of cancer was confirmed by autopsy.

The tumor in cancer of the panereas is not always to be felt, and, as in Case XLVIII, there may be ascites, which renders it difficult. The mass may be between the navel and the margin of the right lobe of the liver, as in our case. It is deep seated, not mobile, variable with the degree of distention of the stomach and intestines. The involvement of the adjacent parts may give to it the characters of a deep-seated, dense, massive tumor. Bear in mind that in

very thin-walled persons, particularly in women with enteroptosis, the pancreas can be felt with distinctness, but the conditions are very exceptional in which it could be mistaken for a tumor.

Case XLVIII. Intense Jaundice; Progressive Cachexia; Ascites; Tumor in Epigastric Region.—E. V., aged thirty-four years, admitted to Ward C, October 24th, complaining of dyspepsia and jaundice. Family history is good.

With the exception of chills and fever fifteen years ago, he has been a very healthy man. For a year he does not think he has been in his usual health, feeling tired and out of sorts; but has had no nausea and no vomiting. For about two months he has been losing rapidly in weight, and has had uncomfortable sensations in the abdomen after eating. A month ago jaundice developed, and has gradually become very intense. He has had no severe pain. The upper part of the abdomen has been a good deal swollen. He came to hospital on account of the jaundice, weakness, and progressive emaciation. Patient presented all the characters of severe obstructive jaundice. He is much emaciated; skin everywhere of a deep yellow color; no fever; pulse, 76. The abdomen is distended, particularly in the upper zone. It is tympanitic in front and dull in the flanks, with well-marked movable dullness. No peristalsis seen in epigastric region. The prominent tympanitic zone extends as low as the umbilious. On deep pressure in the right epigastric region, between the navel and the costal margin there is a hard nodular mass, difficult to outline, owing to the distention. There is enlargement of the lymph glands. The test breakfast showed the presence of free hydrochloric acid, and the stomach did not appear to be dilated. Examination of the heart and lungs was negative. On October 28th and on November 1st he had some stomach distress, for which lavage was practiced, and a quantity of dark, coffee-ground-looking material was washed out. On November 2d it was noted that the distention in this case was unusual; no coils were to be seen; no peristalsis. The tympany extended to the fifth rib on the left side, and a little above the costal margin on the right side. The stools were clay-colored, rather firm, and he constantly had to take purgative mineral waters. Microscopically there was sometimes a good deal of fat. There was never any sugar in the urine, which had the usual characters of this secretion in obstructive jaundice.

The intensity of the jaundice, the rapid emaciation, without enlargement of the liver or recognizable disease of the stomach, and the presence of a deep-seated tumor mass led to the suggestion of pancreatic disease. The tumor was difficult to feel satisfactorily owing to the very great distention of the epigastric region, and as the patient's physician bad suggested that it was possibly due to gallstones, and as he was himself very anxious that something should be done, Dr. Halsted performed an exploratory operation. More fluid was found in the peritonæum than we had expected. The remarkable distention in the epigastrium was due to the floating up on the top of the fluid of the colon and small bowel. The gall bladder was found to be dilated; but the mass which had been felt was a deepseated growth in the situation of the head of the pancreas. The patient was a good deal relieved by the operation, but no essential change took place, and he gradually sank, becoming very intensely emaciated, and died November 18th.

The post-mortem by Dr. Flexner showed the head and body of the pancreas to be the seat of a tumor mass. The growth had infiltrated the wall of the duodenum, and the posterior wall of the stomach was involved directly from the tumor in an area eight centimetres in extent. The gall bladder and ducts were much dilated with dark, thick bile.

<sup>\*</sup> Tuberculous Peritonitis, Johns Hopkins Hospital Reports, vol. ii.

To the case of possible cyst of the pancreas I shall only just refer, and show you the chart, as Dr. Halsted, in whose practice it occurred, will publish it with full details.

The man (Case XLIX), aged about thirty years, was admitted April 14, 1893, with a greatly swollen abdomen, measuring over forty inches in circumference. His illness dated from January, 1890, when, without any fall or injury, he had for three days severe colic, not associated with vomiting or with jaundice. A month later he had a second attack, also lasting three days; in this one he vomited, and noticed for the first time swelling of the abdomen. Then the attacks recurred frequently, two or three a month, each time with nausea, vomiting, and colic, and the abdomen progressively enlarged until July, 1890, after which he had no further attacks of colic. The abdomen remained large, but his general condition was good and he was able to do light work. In July, 1892, he fell out of a wagon, jumped up, got into it again, but immediately had a severe attack of colic, and had to go to bed in a hotel near by for two days. He had nausea, vomiting, and great pain. The swelling gradually disappeared, and in ten days the girth of the abdomen decreased from forty-three to thirty-one inches. He had profuse diarrhea, but he does not think there was pus or blood in the stools. He gained in weight rapidly, and went to work. He was married in October, and remained well until January of this year, when he felt his trousers were tight at the waist; and during the past three months, without colic, vomiting, or jaundice, the abdomen has gradually increased in size.

Fig. 36. A cyst in the abdomen, probably of the pancreas (Case XLIX.)

A truly remarkable history! The man was unusually intelligent, and insisted that his statement about the complete disappearance of the tumor after the fall from a wagon was correct. When he came under observation the entire abdomen was distended, particularly in the upper zone; the ensiform cartilage and the lower ribs were everted. The distance from the tip of the ensiform cartilage to the navel was 21.5 centimetres; from the navel to the pubes, 16.5 centimetres. The wall was tense and elastic; fluctuation was readily obtained. The percussion outlines are given in the chart. There was resonance only in the epigastric angle, in the hy-

pochondriac regions, and in the flanks. In the right inguinal region there was an elevated ridge. Dr. Halsted incised and drained the cyst, which was found adherent to the abdominal wall. Eighteen litres of a dark, coffee-colored fluid were removed, which was alkaline in reaction, contained granular debris and much altered blood, fresh red blood-corpuscles, and a few large cells deeply stained with blood pigment.

The patient had a tardy convalescence, but ultimately left the hospital in good condition. The diagnosis of pancreatic cyst in this case rests rather on general than special grounds. The gradual development with attacks of colic, the persistence without serious damage to the health, the disappearance once after a fall, the gradual reaccumulation—all point to a retention cyst. There were no features pointing to loss of the function of the pancreas—neither

fatty stools nor glycosuria. Large pancreatic cysts may fill, as did this one, the entire abdomen; in long-standing cases the contents consist, as a rule, of altered blood, and while an amylolytic ferment, which is not in any way distinctive, may exist, the trypsin, which would be definite and conclusive, is usually not present.

Many of the cases described as cysts of the pancreas are really instances of hæmorrhage into the lesser peritonæum. Let me refer you to Mr. Jordan Lloyd's suggestive and timely contribution.\* From four of his conclusions you may gather the gist of the whole matter:

- 1. "That contusions of the upper part of the abdomen may be followed by the development of a tumor in the epigastric, umbilical, and left hypochondriac regions."
- 2. "That such tumors may be due to fluid accumulations in the lesser peritoneal cavity."
- 3. "That, when the contents of such tumors are found to have the property of rapidly converting starch into sugar, we may assume that the pancreas has been injured."
- 4. "That many such tumors have been regarded as true retention 'cysts of the pancreas,' and that this opinion has been formed upon insufficient evidence."

(To be concluded.)

#### A CASE OF TRAUMATIC CHORDEE.\*

By W. M. NELSON, M. D., C. M., SYBACUSE, N. Y.

The deformity I desire calling to your attention this evening is one that must be rather uncommon, as the greater number of standard works in the English language on surgery and genito-urinary disease make no mention of it, and the few that do merely state that such a condition has been met with, and have little or nothing to say regarding its ætiology, pathology, and morbid anatomy. Morrow's System of Genito-urinary Diseases, which is supposed to mirror the best thought and knowledge of this branch of science, devotes but a few lines to this deformity and its causation.

Dr. F. Tilden Brown, author of the article mentioned, says that Otis has reported three cases following internal urethrotomy, all of which got well in from two months to a year, but that he (Dr. Brown) has seen several cases of the same character that after slight improvement bade fair to remain during life. He states that these curvatures are due to a cavernitis of chronic course with exudation into the meshes of the cavernous tissue, which exudation may be unilateral or bilateral, and, of course, producing lateral and upward curvatures respectively.

In the American Text-book of Surgery is found a statement that escape of blood into spongy tissue is sometimes

<sup>\*</sup> British Medical Journal, November 12, 1892.

<sup>+</sup> Read before the Syracuse Academy of Medicine, April 3, 1894.

followed by upward, lateral, or downward curvature, that may be so marked as to interfere with or render coitus impossible.

By "spongy tissue" I suppose is meant the erectile tissue of both corpus spongiosum and corpora cavernosa, as loss of function of a portion of one of these bodies alone would hardly produce three different forms of curvature.

The only complete exposition of the ætiology and pa thology of disease of the erectile bodies of the penis is given by Ernest Finger in his work on Syphilis and the Venereal Diseases, published in 1892. Before giving a brief résumé of what he has to say about cavernitis, it is as well to explain that he does not recognize a corpus spongiosum, but groups the erectile tissues of the penis under the one term—corpora cavernosa.

"If the blennorrhagic process be very acute, or the parts subjected to violent coitus, catheterization, strong injections, etc., the inflammation of the mucous membrane may extend by continuity to the corpus cavernosum itself, causing inflammation, suppuration, or necrosis of that part. If the process proceeds from the follicles, it is customary not only to have a perifollicular inflammation but also an inflammatory infiltration of the cavernous body. When this last is the result of extension only it is apt to be circumscribed, but when the cavernous tissue is directly affected the inflammation is more apt to be diffuse.

"More ominous than the peri-urethral are the cavernous infiltrates proper, which may localize themselves in all three corpora cavernosa of penis. They are developed as moderately firm, seldom distinctly circumscribed infiltrates of one or other corpus cavernosum, running a slow course and accompanied by acute inflammatory phenomena. They rarely affect a whole corpus, usually only a part of it, and appear as indistinctly circumscribed, painful knots which increase the volume and alter the consistence of the corpus itself, and place it in a condition of partial erection, and, since the other two corpora are flaccid, there occurs an arching of the half-erected penis, whose convexity is formed by the affected corpus.

"If all three corpora take part in the inflammation, priapistic erection of the whole penis results. After disappearance of the inflammation the inflatrate may be absorbed and the integrity of the tissue restored. On the other hand, the inflatrate may remain, become organized, and induration of the affected corpus result.

"Finally, the infiltrate may become purulent and break in any direction, and after healing there remains, of course, partial destruction of the corpus. Induration or abscess formation may make a corpus partially or wholly functionless, so that the erection is incomplete and a bending of the penis toward the affected corpus cavernosum results."

After these few preliminary remarks, I will attempt to describe the condition obtaining in a young man now under my care, and trust that the photographs to be passed round will counterbalance the defects in my word picture.

W. W., aged twenty-three years, was referred to me by a fellow of this academy on January 11, 1894. The patient stated that there was a downward curving of the penis during erection, and that this condition had first appeared three weeks after

an internal urethrotomy which was performed in a New York hospital, May 17, 1890. He also complained of frequent nocturnal emissions that were seldom the result of lascivious dreams, slight discharge of muco-pus, inability to project his urine—the stream being of the waterfall character—lassitude, vertigo, loss of ability for consecutive thought, tachycardia,

Fig. 1. Incomplete erection (showing corrugation).

lumbar pain, and occasional intercostal neuralgia. He was also practically impotent, due not only to the curvature but also to the orgasm taking place prematurely.

Examination.—A No. 30 (French scale) sound passed by its own weight. Meatus large, but neither sunken nor abnormally placed. Secured an erection by the patient's rubbing in a little simple ointment, when the penis assumed the curves shown in photographs.

Neither while the sound was in the urethra nor during erection could anything abnormal be detected by palpation.

Fig. 2.- Complete election.

Endoscopic Examination.—Bulbous portion of the urethra of a deep livid red, finely granular, or stippled and partially covered with muco-pos, which was removed easily.

On reintroduction of tube the membranous urethra was seen to be in a somewhat similar condition, but with smoother surface. The pendulous urethra was fairly normal for the first couple of inches from the meatus, but beyond that it was first congested, then faintly stippled, and finally merged into the condition of the bulbous.

Some rigidity of the congested and stippled pendulous ure-

thra was shown by the depth of funnel produced by the tube. No cicatricial tissue observed anywhere.

The following is a transcript of the hospital record of this case:

May 16, 1890.—Examination with bulbs: Stricture tissue, caliber 22, is found from an inch and three quarters to three inches and a quarter from the meatus.

17th.—Ether anæsthesia; urethra irrigated. Bulbs again used, with following results: Meatus, 30; stricture from an inch and a quarter to three inches. Meatus incised with meatotome, and urethra, from an inch and a quarter to three inches and a quarter from the meatus, was cut to 32 by an Otis urethrotome.

Stricture tissue dense, and several cuts were made before the instrument could be turned to 32. The 30 bulb stopped at three inches and three quarters, and this was cut to 34. Sounds were then used, but 33 would not pass. A 33 bulb showed stricture at two inches and a quarter, and this was cut to 33.

Sound No. 34 was passed, and will be used to maintain patency of urethra.

18th.—Temperature, 100°.

20th.—Considerable hæmorrhage at 11:48 p. m., and chills, Penis irrigated and strapped to abdomen. Whisky and quinine administered,

22d.—Sounds Nos. 33 and 34 passed, followed by hæmorrhage.

26th.-Passed sounds of same caliber as last.

28th.—Discharged.

The patient, who is exceptionally intelligent, gives further details—viz, that at the time of the operation there was a free urethral discharge of pus, of the existence of which he thinks the operator was unaware. Also that, on the third day after the operation, he had an erection during which something seemed to give way, and this sensation was immediately followed by profuse hemorrhage. For three months after leaving the hospital there persisted a free discharge of pus; after this period it became less in quantity and muco-purulent in character.

Three weeks after the operation he first noticed the curvature, and states that it was as pronounced then as now. No pain has accompanied erection or ejaculation at any time. He has had one attack of pseudo-gonorrhoma since operation, but this yielded to treatment quickly, so far as the acuteness was concerned, and his condition resumed its former character.

From the history and status præsens, I think there can be no doubt of there having been an exudative inflammation of that portion of the corpus spongiosum that corresponds with the concavity of the incurvation, and to those who hold one of the two theories regarding the pathology of ordinary chordee the title of this paper will not appear inappropriate.

The history of this case shows conclusively, I think, that more than stricture tissue was incised during the operation, and that the sheath of the corpus spongiosum was nicked or cut through, leaving the erectile tissue unprotected, or even slightly wounded. The state of things, then, being favorable to tearing of the spongy body, it promptly took place during the distention accompanying the first erection, and perhaps further damage followed the introduction of sounds two days later.

The statement of the patient, to the effect that at the acme of the erection he felt something give way in the passage and that hæmorrhage immediately followed, is corroborative of this.

This tearing of the erectile tissue originated an inflammation that was aggravated, probably, by the presence of the urethral discharge, and the inflammatory process went on till obliteration of the meshes of the affected portion of the corpus spongiosum took place.

It may not be out of the way to say here that free hæmorrhage and other complications of internal urethrotomy seldom or never occur when stricture tissue alone is incised; but the reverse holds good when the healthy mucous membrane and deeper structures are wounded—events not at all unlikely to occur in the use of instruments the knives of which are not directly under the control of the operator.

Treatment.—This has been in some measure a success. The granular condition of the urethra cleared up under the topical applications of silver-nitrate solutions of increasing strengths.

The use of full sized sounds, together with deep injections of glycerine of tannin, has lessened the frequency of emissions. The incurvation has slightly but appreciably decreased under massage, inunctions of protiodide of mercury and atropine, and the use of electrolysis.

Massage of the whole body, cold spinal douches, and the internal administration of phosphorus and nux vomica about complete the course of treatment followed.

406 WARREN STREET.

# THE PRACTICAL WORKINGS OF THE NEW LAWS FOR THE STATE CARE OF THE INSANE.\*

BY CARLOS F. MacDONALD, M. D.,
PRESIDENT OF THE NEW YORK STATE COMMISSION IN LUXACT:
PROFESSOR OF MENTAL DISEASES IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE;
LATE LECTURER ON INSANITY IN THE ALBANY MEDICAL COLLEGE.

THE fact that the Medical Society of the State of New York is in large measure entitled to credit for the original impulse and the early effort which resulted in two greatly advanced steps taken by the State in dealing with its dependent insane, first in 1836 and again in 1865, and also that it actively participated in the final movement which culminated in the passage in 1890 of the so-called State Care Act-steps which may not inaptly be termed epochs in the progressive development of this most important subject of the State's relations to those of its citizens, who, afflicted by insanity, are thereby reduced to dependence on the State's charity for their subsistence-would seem to be sufficient in itself to warrant the writer, who is the medical member of the only official body of the State charged with the administration of the laws relating to the insane and the general supervision and oversight of the hospitals, asylums, homes, and retreats, both public and private, established for the care and treatment of this unfortunate class, in presenting to the society an outline of what that administration has done and is doing, and of the general condition of the insane in the State at the present

<sup>\*</sup> Read before the Medical Society of the State of New York at its eighty-eighth annual meeting.

time as contrasted with the state of things which formerly prevailed in relation thereto.

Furthermore, in view of the great frequency and widespread prevalence of insanity throughout the civilized nations of the globe, as compared with other diseases, many of which are properly regarded as of very great importance, and respecting whose nature, symptoms, and treatment we, as physicians, are required to be well informed; and in view of the fact that insanity involves a wider range of interests and is more far-reaching in its effects-whether as regards the individual sufferer, his family, or the community at large-than any other disease to which mankind is liable, the subject of the care and treatment of the insane is obviously one of great public importance; while to the medical profession, whose members must encounter cases of mental disease with more or less frequency from the very outset of their professional practice, it has a peculiar interest. Then, too, our lawmakers, in recognition of the fact that insanity is a disease, or, in other words, a medical question, have conferred exceptional powers upon our profession in the matter of making certificates in lunacy, whose effect is to deprive persons of their liberty, the deprivation of this constitutional right being in most cases of insanity a necessary incident to the patient's proper treatment and safe keeping as well as essential to the public safety. Such being the case, it is eminently proper that the medical profession, to whom alone is delegated this extraordinary power-at least so far as the initial legal step is concerned-should insist that those who are deprived of their liberty by reason of the action of its members are properly housed, fed, and clothed, and supplied with competent supervision and medical care and treatment. In a word, it is the duty of the medical profession to insist that the insane shall be amply provided with everything which medical science has declared to be essential to the restoration of those who are recoverable and to the proper care and comfort of those who do not recover.

Our interest, both as physicians and as public-spirited citizens, should especially be invoked in behalf of the dependent insane, in whose ranks are found representatives of all professions, trades, and occupations, and most of whom were self-supporting, respectable citizens before the onset of their disease, and who, though necessarily now maintained at public expense, are, with few exceptions, in no proper sense of the term, paupers—the term insane pauper being properly applied only to those who were paupers before they became insane. It should be borne in mind in connection with this subject that many self-supporting citizens are not possessed of any large amount of means over and above their immediate necessities, so that if the hard-working professional man, mechanic, farmer, teacher, or laborer falls a victim to insanity, he must necessarily, sooner or later, become a dependent upon the public bounty, even though he may have been a taxpaver before the onset of his disease.

In support of the claim here indicated respecting the importance of insanity as compared with other diseases, the writer would recall the trite facts that the symptom 8,423; and in licensed private asylums, homes, and re-

group which we denominate insanity is in every case but the outward expression, on the mental side, of existing disease or disturbance of the brain, the organ through which the operations of the mind are made manifest to us-the term mind being here used in a physiological sense, and implying the sum total of those brain functions which are known as thought, feeling, and will; that insanity is a disease which invades all classes and from which no one, be he rich or poor, high or low, can claim exemption; that it involves to its victim, to his immediate friends, and to the community a wider range of interests than any other disease. To the individual it involves a loss or perversion of that faculty which alone distinguishes man from the lower animals; it also involves usually the loss of the liberty guaranteed to every individual by the Constitution; it involves the loss of control of his property and affairs, a disturbance or destruction of his social and business relations, enforced separation from his family, and, if his disease happens to take an unhappy form, it involves great mental anguish and suffering, and possibly the loss of his life through self-destruction or exhaustion; or, if the case fail of recovery, it involves a prolonged and often weary existence, which might properly be termed "a living death." To the individual's family it usually involves great anxiety and distress, occasioned by the sad spectacle of a loved one with reason dethroned, and the putting of this loved one away in the care of strangers; it involves the stigma which society unfortunately and unjustly attaches to the taint of insanity, and which is usually regarded by the relatives of the sufferer as something akin to shame and distress. It frequently involves a cutting off of the source of income, especially if the afflicted one be the breadwinner of the family; also the added expense of commitment to and maintenance in a hospital for the insane; and finally, it involves exposure of the lives and property of the family to danger from violent and destructive tendencies of the patient. To the community it involves great danger to life and property from the acts of homicidal and dangerous lunatics; also a large loss to the body politic by the withdrawal from the ranks of wage-earners of the earning capacity of many thousands of individuals-substantially all of the insane being adults and for the most part in the active stage of life; and last, though by no means least, it devolves upon the community an enormous burden of taxation incident to providing for and maintaining hospitals and asylums for the custody and care of a vast army of insane people, there being to-day in the public and private hospitals and asylums, homes and retreats in the State of New York alone upward of eighteen thousand insane persons held under certificates of lunacy, not to mention the large number of unapprehended, unrecognized, and socalled "border-land" cases, which are liable at any time to call for medical attention and advice.

The number of committed insane in the State of New York on the first day of January, 1894, was: In State hospitals, exclusive of the Hospital for Insane Criminals, 8,901; in the so-called exempted county system, embracing the asylums of New York city and Kings County, 8,423; and in licensed private asylums, homes, and re-

treats, 830-making a total of 18,154. Of this number, 8,500 were men and 9,654 women. The aggregate cost of lands, buildings, equipment, and furniture devoted to their uses on October 1, 1893, was, in round numbers: For the State hospitals, \$11,000,000; for the asylums of New York and Kings Counties, \$4,600,000; and for the licensed private institutions, \$1,110,000-making a total cost for this purpose of \$16,710,000. The cost of maintenance of the insane for the fiscal year ending September 30, 1893, was, in round numbers: State hospitals, \$1,837,000; asylums of New York and Kings Counties, \$1,254,000; licensed private asylums, \$480,000-making a total annual cost for maintenance, in round numbers, of \$3,376,000. The institutions in the State, not including the Hospital for insane Criminals, are: State hospitals, 8; county asylums of New York and Kings, 6; licensed private institutions, 17; or 31 in all.

The foregoing statement of facts and figures is here presented merely for the purpose of calling attention by way of introduction to the magnitude and importance of the disease under consideration, and as suggestive of the wide range of interests it involves, whether viewed from a professional, sociological, or economical standpoint.

The first attempt on the part of the State of New York to provide State care for the insane was made nearly sixty years ago, when, in 1836, the Legislature, in response to a memorial from this society, praying for the establishment of a suitable State asylum for the insane, created the State Lunatic Asylum at Utica, now the Utica State Hospital. Prior to that time the insane poor, both acute and chronic, were mostly cared for in county or town poorhouses, there being substantially no other provision for them. Provision was made in the original charter of the Utica Asylum whereby patients who failed to recover after a certain period of time or who should be pronounced incurable, might be removed to the county poorhouse, upon the superintendent's certificate that the patient was "incurable" or "not likely to be benefited by further treatment, and could probably be made comfortable in the poorhouse." This was a most inhumane and barbarous provision, and one that was continued in operation under certain modifications, though with practically the same results, until the creation of the State Commission in Lunacy in 1889, and the subsequent passage of the State Care Act in 1890; so that while the establishment of the State Lunatic Asylum in Utica in 1836 \* was a practical recognition on the part of the State of the principle of State care, its beneficence extended only to State care for the acute or recent insane, while at the same time it countenanced, or at least tolerated, a system of county or poorhouse care in its worst form by permitting the superintendent of the asylum, in his discretion, to transfer to county houses under the guise of incurability the friendless, the violent and destructive, the filthy and infirm, and the feeble and helpless-the very classes which of all others most need the fostering care and protection of the State. This pernicious system continued for a period of nearly thirty years, during which time the poorhouses became filled to overflowing with mentally

afflicted human beings, who were restricted to the merest pretense of custodial care and maintained in a spirit of parsimony whose chief apparent ambition was to see on how small a pittance body and soul could be kept together. The keeper of one county poorhouse publicly proclaimed in 1889 that he maintained the insane of his county at a cost of ninety cents a head per week, including food, clothing, bedding, warmth, lights, and medical attendance.

Subsequently, in 1865, again through the active agency of this society, which, through its secretary, the late Sylvester D. Willard, investigated and reported upon the condition of the insane in the various poorhouses of the State, the Legislature passed the "Willard Asylum Act," which provided for the establishment of a State asylum for the chronic insane. This act, which has been aptly characterized as the "second era of the lunacy legislation of the State-that of State care of the chronic insane," contemplated the removal of all the chronic insane from the county houses to the Willard Asylum, and aimed to prohibit the counties, except New York, Kings, and Monroe, from thereafter caring for their chronic insane. So that, with the establishment of the Utica Asylum for the acute insane and the Willard Asylum for the chronic insane, the State had, theoretically at least, adopted the policy of caring for all its dependent insane. But through delay in establishing and extending the Willard institution, and despite the subsequent opening of the Hudson River State Hospital and the Homeopathic Hospital in 1871, the Buffalo Asylum in 1880, and the Binghamton Asylum for the chronic insane in 1881, the supply of accommodations for the State's insane was still inadequate to the demand. This lack of accommodations in the State asylums was made the basis of an appeal to the Legislature by county authorities and others to permit the counties to again care for their chronic insane. In response to this appeal the Legislature granted exemption to several counties by special act, and also in 1871 authorized the State Board of Charities, in its discretion, to grant licenses to counties to care for their chronic insane under certain conditions, and to exempt such counties from the Willard Act, and also to revoke said licenses in case of failure to comply with the terms and conditions imposed. Under the provisions of this scheme for a return to the wretched county system, the State Board of Charities, a majority of whose members were adherents and advocates of separate provision for the chronic insane in either State or county asylums, granted licenses to nineteen counties, in which were established so-called county asylums, located for the most part on the grounds of and adjacent to the poorhouses and under the same management, being, as a matter of fact, in most cases merely an integral part of the poorhouse, under the control of a lay keeper, and conducted on a similar basis as regards the standard of care.

One of the evils of this system, aside from the wretched surroundings and care to which it consigned the dependent insane, was that it pauperized substantially all who failed of recovery after a year's residence in a State asylum, and even those who were transferred from the "acute asylums" to the Willard and Binghamton Asylums as incurable were

<sup>\*</sup> Opened for the reception of patients in 1843.

made unhappy by the lower standard of care and treatment which they received at the latter institutions, as well as by the implied fact that hope of recovery in their cases had been abandoned. Furthermore, it was found to be the practice of many of these exempted counties to receive into their so-called asylums acute cases directly from their homes, which was a clear violation of law. And yet, strange as it may now appear, the licenses granted to these counties by the State Board of Charities were permitted to stand in the face of the evils here referred to; and, moreover, and still more strange, the board which granted them indirectly encouraged and commended this system in some of its official reports.

The State Charities Aid Association, a voluntary organization, in its report on the insane for 1893, says: "Meanwhile, the humane thought of the day being thus earnestly engaged in trying to solve the difficult problem of how to obtain for the indigent insane the best treatment that an advanced civilization could give them, the pernicious legislation of 1871, already referred to, was slowly but surely sapping the vitality of the reform movement of 1865 in behalf of the chronic insane. County after county applied for and obtained exemption from the Willard Act. By October 1, 1887, nineteen counties had thus been authorized to keep their milder cases of insanity. It is true these exemptions were granted by the State Board of Charities under promise from the counties 'to give their insane just as good care as the State gave'-promises, alas! never kept. No longer, as of old, were the chronic insane to go from poorhouse to State hospital, but from State hospital to poorhouse. Gradually, year by year, and so slowly that we scarcely realized it, the poorhouse officials were tightening their grasp upon these poor people, until suddenly we were confronted by the alarming fact that the supervisors of one third of the counties were arrayed in favor of the poorhouse system."

This was the condition of affairs when, in 1889, the State Commission in Lunacy was created, to which body was transferred, among other things, the power hitherto possessed by the State Board of Charities in the matter of granting exemptions from the Willard Act. It is needless to say that the Commission in Lunacy promptly declined to grant any further exemptions to counties; and how the commission, after having made a tour of the county asylums of the State, exposed and denounced what it there discovered in its first annual report to the Legislature in 1889, is a matter of recent history in relation to the insane which is too well known to all who are interested in the welfare of this class to call for more than passing notice here.

The State Charities Aid Association, which for years had strenuously opposed the county care system, and had unsuccessfully striven for two successive years to induce the Legislature to pass its bill for State care of the insane, in the report above referred to says: "As one reads the first annual report of the Commission in Lunacy, written in 1890, glowing with indignation as it recounts the sufferings of these poor people, one is surprised to find how little progress had been made in all those years. The system of poorhouse care has proved itself radically defective. Thank

God! this horrible system is now a thing of the past." And again in the same report: "Heretofore the State Commissioner in Lunacy had almost no power beyond that of inspection and report. He had neither office nor clerical assistance, and could accomplish but little. When, therefore, the Legislature of 1889 created a State Commission in Lunacy of three members, with greatly enlarged powers and duties, a much-needed reform had been effected. . . . The thorough inspection made by this commission of the asylums of the entire State, and their outspoken denunciation of the dreadful condition of the insane in the exempted county asylums, as submitted in their first report to the Legislature, may justly be regarded as the deathblow to the poorhouse system."

Following this first report of the Lunacy Commission to the Legislature, the State Charities Aid Association, under the able leadership of that stanch friend of the dependent insane, Miss Louisa Lee Schuyler, again brought forward its bill for State care, and this time succeeded in passing it, in spite of "organized, vigorous, and determined opposition emanating from supervisors and superintendents of the poor of exempted counties."

The essential features of the State Care Act may be briefly summarized as follows: The abolition of the unscientific and inhumane legal distinction between acute and chronic insanity; the division of the State by counties into hospital districts, and compelling the hospitals to receive and care for all the dependent insane, both acute and chronic, within their respective districts; requiring the Commission in Lunacy to cause the removal of the insane poor from the county houses to State hospitals as fast as accommodations could be provided therefor; providing for the erection of comparatively inexpensive buildings of sufficient capacity on the grounds of existing State hospitals, the cost of erection, equipment, and furnishing of said buildings not to exceed the sum of \$550 per capita, upon plans to be approved by the State Commission in Lunacy; requiring all county superintendents of the poor, or town, county, or city authorities, before sending a patient to any asylum, to see that he is in a state of bodily cleanliness and is comfortably clad, in accordance with regulations to be prescribed by the president of the commission; requiring that, in the case of transfer of a female patient, she shall be accompanied by a female attendant, unless she be transferred by her husband, father, brother, or son, and that, after said patient or patients have been delivered to the managers or trustees of the State hospitals, the care and custody of the county authorities over said insane persons shall cease, the expense of such transfer to be paid by the State; after sufficient accommodations shall have been provided in State institutions for all the pauper and indigent insane of all the counties of the State, the expense of such care, maintenance, treatment, and clothing of indigent insane patients in State hospitals to be no longer a charge upon any county, after the 1st of October next ensuing, but the cost of the same shall be paid out of the funds provided by the State for the support of the insane; that, after the board created by the State Care Act for the purpose of districting the State shall have certified to the Secretary of State that sufficient

accommodations have been provided in State institutions for the indigent insane, no insane person shall be permitted to remain under county care, and that all insane who are now or may hereafter become a public charge shall be transferred to a State hospital, without unnecessary delay, there to be regarded and known as the wards of the State and to be wholly supported by the State; requiring the State Commission in Lunacy, whenever it shall deem it necessary and expedient, by reason of overcrowding, or in order to prevent the same, to recommend in its annual report to the Legislature the erection of such additional buildings on the grounds of any or all State hospitals then existing as shall in the judgment of the commission provide sufficient accommodations for the immediate and prospective wants of the insane of the State, or, if said commission shall deem it more expedient, it shall recommend the establishment of another State hospital or hospitals in such part of the State as, in its judgment, will best meet the requirements of the dependent insane; requiring the State Commission in Lunacy to hereafter furnish the Comptroller, on or before the 15th of September in each year, an estimate as to the probable number of persons who will become inmates of the respective State hospitals during the year beginning on the 1st of October next ensuing, and the cost of the necessary buildings and equipment, if any, which will be required to carry out the provisions of this act; requiring the managers or trustees of each of the said hospitals, on or before the 15th of September in each year, to furnish to the Comptroller an estimate of the cost of maintaining the probable number of patients who will be inmates of the respective hospitals during the year beginning on the 1st of October next ensuing; on the basis of these estimates the Comptroller to report, in his next annual report to the Legislature, his estimate of the amount to be provided for by the State for the support of such insane patients, and for the erection and equipment of such buildings as may be recommended.

The counties of New York, Kings, and Monroe are exempted from the operations of the State Care Act, but provision is made that whenever these counties, or any one of them, shall desire to be included under the provisions of the act, application may be made in writing to the Governor by the local authorities to transfer their asylums to the State upon such terms and conditions as may be specified in their application, the Governor to transmit the application to the Board for the Establishment of State Insane Asylum Districts created by the act, whereupon said board shall examine into the condition of the buildings, lands, and appurtenances sought to be transferred with reference to their value, and to ascertain whether such property is suitable for the purpose of a State hospital for the insane, and, if so, whether the terms and conditions proposed are just and proper, and to report its findings and conclusions to the Governor, whereupon the Governor shall transmit to the Legislature the report of said board with such recommendations, if any, as he may deem proper for the conversion of such county asylum into a State hospital for the insane.\*

The act, moreover, revoked all exemptions heretofore granted to counties to care for their insane and prohibits the granting of further exemptions; it also provides that no insane person now or hereafter under the care of any State hospital shall be returned to or committed to the care of any superintendent of the poor of any county or to any other town, county, or city authorities, and the said superintendents of the poor are forbidden to receive any such patient who may be returned or committed to them in violation of the act.

By the adoption of the State Care Act, as outlined above, the State not only emphatically reaffirmed its policy of State care, which began in 1836, and which was extended in 1865, but unequivocally committed itself to the extreme and logical limit of the principle, in fact as well as in theory, that the dependent insane are the wards of the State and that the interests and maintenance of the insane should be confided exclusively to the State; while the terms of the act render it easily workable and susceptible of unlimited extension to meet the increasing demands which may from time to time be made upon it.

Following the passage of the State Care Act, and supplemental thereto, the Legislature appropriated \$454,850 for the erection of additional buildings upon the grounds of the existing State hospitals, which, together with the partial completion of the St. Lawrence State Hospital, at Ogdensburg, were sufficient to provide accommodations for all of the insane then in the custody of the counties as well as for recent cases.

The erection of these buildings was rapidly accomplished within the per capita cost, \$550, fixed by the act, and in 1893 the board was able to certify that sufficient accommodations within the purview of the statute had been provided, whereupon the Legislature, upon estimates furnished by the commission, passed an act known as Chapter 214 of the Laws of 1893, for the care, medical treatment, clothing, support, and transportation to State hospitals of the insane poor. This act provided for the levying of a tax of a third of a mill upon the taxable property of the State for the support of the State hospitals, the sum realized from this tax amounting, in round numbers, to \$1,350,000, which, together with the estimated receipts of the State hospitals for the support of private patients and from other sources, brought the sum up to, in round numbers, \$1,650,-000. This act, which went into effect on October 1, 1893, provides for the submission to the Commission in Lunacy by the hospitals of itemized monthly estimates for their current expenses, these estimates to be revised by the commission as to quantity, quality, and price of supplies and wages, and subsequently to be certified to the Comptroller for payment of the amount of the estimates, as revised, to the respective treasurers of the State hospitals.

Having thus imperfectly outlined substantially all the legislation had for the insane, including the creation of the Commission in Lunacy in 1889—which in reality was the initial step in the final effort for the establishment of State care for the dependent insane—down to and including Chapter 214 of the Laws of 1893, which carried this humane and beneficent measure into full operation, it becomes

<sup>\*</sup> Under this provision the Monroe County Asylum was converted into the Rochester State Hospital in 1891.

pertinent to inquire as to what have thus far been the practical results of this legislation. In other words, what improvements, if any, have been made in the methods governing the commitment and general and medical care and treatment of the insane, and in the condition and management of the hospitals and asylums established and maintained for the benefit of this unfortunate class; also what, if any, advantages are derived to the taxpayers of the State as a result of the new method of supporting the dependent insane?

(To be continued.)

# NEURALGIA OF THE GREAT OCCIPITAL NERVE, ASSOCIATED WITH SYMPTOMS OF A DESTRUCTIVE LESION OF THE CERVICAL SYMPATHETIC.\* By ALEXANDER B, JOHNSON, M, D,

The following case seems to the writer worthy of recording on account of its comparative rarity, and because the exact locality of the lesion seems a little obscure:

The immediate effect of operation is also of some interest.

J. B. presented himself for treatment on November 1, 1893, on account of severe pain in the right side of the head, which made it impossible for him to work. The patient is sixty years old, married, a railroad conductor, and has always led a temperate life. He denies venereal disease. No alcoholic habit. Malaria thirty years ago. No distinct history of rheumatism. Physical examination shows a robust-looking man, a little senile, not anemic. Heart and lungs apparently normal. Pulse 70, of moderate tension. No atheroma detected in external bloodvessels, but arcus senilis fairly marked in both corneæ. There are several old, white, depressed, irregular, and rounded scars, an inch or more in diameter, scattered over the chest and back. They do not appear to be adherent to the bones, and the patient can not describe them more nearly than to say that they were abscesses which he had many years ago and that they were a long time in healing.

Examination of the urine shows nothing abnormal beyond the fact that the quantity is large during twenty-four hours, with correspondingly low specific gravity. The trouble from which he now suffers began three years ago. At that time he was conductor on one of the railroads in the western part of the State, and had worked long hours with but little sleep for several weeks.

He fell asleep one night sitting by an open window of the moving train, his right side exposed to the draught of air which entered. He awoke chilled and feeling ill. His run finished, he made his way home with some difficulty and went to bed, where he remained for several weeks suffering from "a disease of the kidneys," and from his present symptoms, which are described by him as follows:

"He has severe pain of an aching character which occurs in paroxysms for the most part, and is referred to a point about two inches behind the lobule of the right ear and radiates upward and backward to the vertex. Sometimes he is free from pain for a few hours or a day, and again he suffers more or less constantly for weeks. There is marked tenderness on pressure over an area beginning about two inches behind the lobule of the right ear and spreading out fan-like posteriorly to the ver-

tex. The patient further complains of inability to see well with the right eye, especially when objects are above him. He has pretty constant lacrymation from the right eye, and the right side of his face is flushed. The two last symptoms are more marked during the severer paroxysms of pain. He perspires more freely from the right side of the face. He complains of shortness of breath on exertion.

Objectively, the patient's face has an appearance which is characteristic. The upper eyelid on the right side droops so far as nearly to cover the pupil when the patient looks straight before him; the lower eyelid is also slightly elevated, so that the palpebral fissure is symmetrically narrowed. The right pupil is contracted, smaller than the left, and does not react to light. The right eye is watery, and the entire right side of the face is redder than the left.

There is no paralysis of the face; but the skin and muscles appear less full and feel flabby in comparison with the opposite side.

The patient was examined by Dr. M. A. Starr, who located the lesion in the cervical sympathetic, and advised an exploratory operation, having for its object an examination of the superior cervical ganglion and of the cord above and below it, believing that the lesion being evidently a destructive one, a new growth capable of removal might be found which was causing the paralytic symptoms by pressure on the ganglion or cord.

The patient had undergone medical treatment of various kinds during the past three years without relief, and a seton had been introduced into the skin behind the ear with slight temporary benefit.

He was quite unable to continue his work, and felt ready to accept any form of treatment which might give him relief from his suffering. It was thought that an incision, exposing at the same time the posterior branches of the upper cervical nerves and the cervical sympathetic, might be made; but a trial upon the cadaver showed that such an incision would have to be quite extensive, and that so many structures would have to be divided that the operation would be a very severe one for an individual advanced in life; and it was decided that an exposure of the sympathetic would suffice in view of the doubtful benefit of the former procedure.

Operation, November 4, 1893. Incision three inches and a half in length along posterior border of right sterno-mastoid, beginning just below the mastoid process. The sterno-mastoid muscle was drawn forward and the internal jugular vein was drawn by means of a blunt hook in the same direction. The internal carotid artery was lifted and search was made for the superior cervical ganglion upon the surface of the rectus capitis anticus major muscle.

The ganglion was found, however, included within the sheath of the internal carotid, to which it appeared to be distinctly adherent.

The adhesions were divided and the ganglion was freed, as well as the cord below, to the extent of two inches.

No abnormity in appearance could be recognized either in the ganglion or cord, and the wound was closed, a small piece of rubber tissue having been inserted for drainage.

This was removed at the end of three days, and the wound was solidly healed at the end of eight days. There was no rise of temperature.

The neuralgic pains from which the patient had suffered disappeared at once after the operation; he had no tenderness of the scalp. The lacrymation and flushing of the face ceased. His pupil on the right side became a little larger and reacted slightly to light, and his right upper eyelid drooped so little that it was scarcely noticeable and did not at all interfere with vision.

<sup>\*</sup> Read before the New York Neurological Society, March 6, 1894.

He left the city at the end of a fortnight entirely free from any pain or discomfort.

This gratifying condition lasted, however, but a few weeks, and at the end of a month and a half all the symptoms had returned, and at the present writing the patient finds himself in no way improved.

Diagnosis.-The neuralgia from which the patient suffered was for the most part confined to the great occipital or posterior branch of the second cervical nerve; the area of distribution of the anterior branch or lesser occipital nerve in the skin immediately behind the ear was not tender, nor was it the seat of pain except to a slight degree occasionally.

The symptoms of lesions of the cervical sympathetic are thus described by Dr. M. A. Starr in his article on that subject in Pepper's System of Medicine, vol. v, page 1263, and following:

"The symptoms of irritation of the cervical sympathetic are dilatation of the pupil, widening of the palpebral fissure, protrusion of the eyeball, pallor of the entire side of the face and head, with slight fall of local temperature and possibly an increased secretion of perspiration, and an increased frequency of the heart.

"The symptoms of destructive disease of the cervical sympathetic are the converse of those just mentioned, and they are all present when the part is seriously involved.

"The patient will then have a marked contraction of the pupil which no longer responds to light, nor to irritation of the skin of the neck, but may change slightly in the act of accommodation. It resists the action of mydriatics. The vessels of the chorioid and retina may be dilated, as well as those of the iris, in which case the patient will feel a sense of weariness on any long-continued attempt to use the eyes. There is no actual disturbance of vision. There is a noticeable narrowing of the palpebral fissure, the upper lid falling slightly, as in a mild state of ptosis, and the lower lid being slightly elevated.

"This is due to the paralysis of the muscles of Müller in the eyelid, which are controlled by the sympathetic. marked symptom, and one which is constant, is a dilatation of the vessels of the face, conjunctiva, nasal mucous membrane, ear, and scalp.

"An increased secretion of tears sometimes accompanies dilatation of the vessels of the skin of the head.

"A difference between the degree of moisture on the two sides of the face on exposure to heat is usually present.

"Palpitation of the heart has been an annoying symptom in many cases. This is usually associated with a marked slowing of the pulse.

"A slight atrophy of the affected side of the face has been observed in several cases, appearing after the disease had existed for some time. The muscles of the cheek feel flabby and are slightly sunken, but the condition does not approach in severity true facial hemiatrophy, nor is it sufficiently rapid to be considered due to atrophic disturbance."

From the symptoms of the patient whose history forms the subject of this paper, it can be seen that he presented in a fairly typical way the condition of paralysis or of a destructive lesion of the cervical sympathetic.

The only other disease with which this might be confounded is possibly paralysis of the third cranial nerve. A comparison of the essential symptoms of the two conditions placed in parallel columns renders the diagnosis sufficiently clear:

Paralysis of the Third Paralysis of the Cervical NERVE.

Eveball immovable except outward and a little downward and inward.

Slight external strabismus often present.

Pupil at first of medium size, becoming gradually and permanently dilated.

No reaction to light. Accommodative reaction

Ptosis complete or par-

Lower lid unaffected.

Vaso-motor symptoms absent.

No disturbance of heart action.

Breathing not disturbed.

SYMPATHETIC.

Movements of the eyeball unrestricted.

Pupil contracted.

No reaction to light. Accommodative reaction may be present.

Ptosis partial, never complete. Lower lid slightly ele-

vated. Palpebral fissure sym-

metrically narrowed. Vaso-motor symptoms

commonly marked. Flushing of the face and

scalp; sweating.

Pulse usually slow. Palpitation of the heart a

common symptom.

Dyspnœa on exertion a regular symptom.

As bearing directly upon the locality of the lesion in the case under consideration, some of the facts known in regard to the origin and course of the fibers of the cervical sympathetic are interesting; many of them, especially the vaso-motor fibers and those which being excited cause dilatation of the pupil of the eye, are derived from the spinal cord; this being shown by experiments on animals, and in certain cases where wounds of the spinal cord in the lower cervical region have caused crossed motor and sensory paralysis attended by symptoms of paralysis of the cervical sympathetic. A case of this kind is described by Brown-Séquard in the Journal de physiologie, vol. vi, January, 1863, in which both pupillary and vaso-motor symptoms were present in a marked degree.

The writer has seen a similar case within a few weeks, in one of the hospitals in this city, where after a fall an injury of the lower cervical and upper dorsal regions was followed by crossed motor and sensory palsy and by wellmarked symptoms of paralysis of the cervical sympathetic. These facts show that symptoms of a destructive lesion of the sympathetic may be caused by some disturbance within the spinal cord. Also, in A Text-book of Physiology, by Michael Foster, sixth edition, part iv, pp. 40, 41, there occurs the following paragraph: "The pupil-dilating influence of the cervical sympathetic may, as in the case of a vaso-constrictor action of the same nerve, be traced backward down the neck to the upper thoracic ganglion, and thence to the spinal cord along the ramus communicans and anterior root of the second thoracic nerve, in the case of the dog, the monkey, and man," It will be remembered that in the case now under consideration the neuralgic symptoms were quite closely confined to the area of distribution of the posterior root of the second cervical nerve-namely, to the great occipital nerve, which therefore could have no direct anatomical connection with the cervical sympathetic fibers outside the spinal canal. Hence the writer thinks it fair to suppose that both sensory and sympathetic symptoms were due to a lesion situated in the spinal cord, small in extent and of a destructive character, the exact location of which it is at present impossible to determine; and, since the sympathetic symptoms were of a nature pointing to the disintegration of nervous material rather than to an irritative process, the writer further believes that such a symptom complex would furnish a contraindication to operative interference, except in cases where some new growth capable of removal was causing pressure upon both the spinal nerve and sympathetic in the neck. The writer is at a loss to explain the immediate temporary benefit of operation in this case, except on the ground that a powerful peripheral impression often has this effect even in organic disease where a slighter one would cause pain.

The writer desires to express his thanks to Dr. M. A. Starr and to Dr. E. C. Seguin for suggestions which have assisted him greatly in the preparation of this paper.

# TOTAL ABLATION OF THE UTERUS FOR FIBROID TUMORS,

BY LIGATION, CUTTING, ENUCLEATION, AND VAGINAL DRAINAGE.

BY R. STANSBURY SUTTON, M. D.,

ALLEGHENY, PA.,
FELLOW OF THE AMERICAN GYNECOLOGICAL SOCIETY;
SURGEON TO TERRACE BANK HOSPITAL FOR WOMEN;
GYNECOLOGIST TO THE ALLEGHENY GENERAL HOSPITAL.

Total ablation of the uterus by a method, the various stages of which make up the title of this brief article, is pressing its claims for recognition and favor.

The extraperitoneal treatment of the pedicle, supported in the abdominal incision, was a good method, and is probably the safest method for inexperienced operators even yet; but the time has arrived when this method will no longer be held in its former high esteem by many operators of experience and aseptic proclivities.

Surgical evolution is of slow growth. It has required an entire decade to pass from the operation as established by Péan and Kæberlé, cultivated by Keith, Hegar, and Bantock, and many others, to an operation which does away with the sloughing stump, the deep sinus, and the long convalescence of forty to forty-five days, to an operation comparatively free from the septic influence of decomposing tissue, the undelayed closure of the entire abdominal wound, and a convalescence varying from eighteen to twenty-eight days. Secondary to these advantages it has been a

transition to a method involving much less expense to the patient or to the hospital which maintains her amid its many charities.

Distinct methods of operating have been given us by many of our own countrymen, able operators; among them I recall Krug, Goffe, Polk, Baer, Baldy, Hall, Byford, Martin, and Joseph Eastman. I have carefully studied these methods and have practiced all of them, excepting that of Byford and the more recent ligation per vaginam of Martin. The outcome of the practical research on my own part is that I have abandoned the extraperitoneal (abdominal) treatment of the pedicle. I can fully indorse the advance as advocated by Krug, Goffe, Polk, Baer, Hall, Baldy, and Eastman.

The Trendelenburg position, with the staff of Eastman, has made the operation with experienced surgeons safe and in most cases fairly easy.

The slight difference between total ablation and leaving a section of the cervix in the vaginal grasp, as advocated by Baer and Baldy, is not of great practical moment in operating; whether this section of cervix is left or not, the method of operating gets rid of the sloughing stump previously left in the grasp of the abdominal wound.

In operating, I sometimes leave the cervix below the internal os, or I take it out, as I think best at the time. But total ablation, without regard to any method of procedure and with the sole object in view of safely removing the entire uterus and its fibroids, has now become a frequent operation in my hands and is accomplished in the following surgical fashion:

The vagina is made aseptic after the suggestions of Krug; the patient is prepared for abdominal section with the most scrupulous detail known to all operators. For several days prior to operation she is given strychnine and quinine, and the time preferred for operation is a day or two before her expected menstruation-I like to take the patient at her best. She is given chloroform or the A. C. E. mixture, never ether, which alone is to my taste objectionable. I prefer chloroform, but I must know the man who administers it; given properly, it is the most satisfactory of all anæsthetics; I have used it in the presence of organic cardiac affections in my operations and no one has been injured by it. The anæsthetic is always preceded by a hypodermic of an eighth of a grain of morphine and a hundred and twentieth of a grain of atropine. and followed at the close of the operation very frequently by a fiftieth of a grain of trinitrin, even when the indication for it is wanting. Chloroform depression occasionally comes on after the patient has been put to bed; the trinitrin is a safeguard.

The abdomen is opened in the median line a distance of four inches, unless the patient is very fat, when all the space from the umbilieus downward is utilized at the start. The mass (uterus and tumor) is now explored with the fingers and hand, if necessary the incision is extended, and the mass is brought through the incision by means of pressure from the loins by the assistant and direct pulling on my part with a screw or forceps or transfixing pin thrust through the mass like a skewer in a roast of beef; the

mass is held well toward the pubis by the assistant, while I pack a half dozen flat sponges in between its base and the intestines. The end of the table (Edebohls's) is now raised still higher, and the abdominal contents descend more completely toward the diaphragm; adhesions of omentum or intestines have already been separated, if they existed. Down the sides of the mass lie the hypertrophied broad ligaments and the hypertrophied Falloppian tubes and ovaries, usually abnormal. Well down below the ovaries and tubes a curved needle (Goodell's), perfectly round, is passed so as to embrace the fold of broad ligament from its outer edge to the wall of the mass. The ligature carried by the needle is of very heavy silk which has been boiled for three hours in plain water, and is tied under the greatest possible strain which it will bear. Above it a short distance a pair of lock-handled, large compression forceps are placed, embracing the ligament up to the mass. The ligament is now divided below the forceps. The opposite side is treated in the same manner. The mass now becomes more movable, freer from its moorings. At this stage of the operation an incision through the anterior peritoneal covering of the uterus may be made above the bladder, and a corresponding incision may be made on the posterior surface on the same plane. The peritoneal layer, front and back, may be stripped down to the vaginal attachment, at which point the uterus may be amputated, and the operation may be concluded as advised by Dr. Baer and Dr. Baldy. But to go on to total ablation: With the fingers feel for the uterine artery low down on the left side and try to carry a second ligature beneath it, keeping close to the wall of the uterus. This ligature, firmly tied, should be left long. The same procedure is gone through with on the opposite side. An incision, front and rear, is made as noted above, and the enucleation of the cervix is carried on, front and rear, to the vaginal attachment. On the sides the scissors complete the freeing process to the vaginal attachment also. During this last manœuvre the uterine arteries, if missed by the second ligature, will spout freely, and are caught up by the hæmostatic forceps and ligated. Eastman's staff is now pushed to the vault of the vagina, and on it the last cutting which liberates the cervix is done; any spurting vessels are ligated. The long ends of the ligature are now carried with the forceps through the vagina, to be left protruding at the vulva. The abdominal side of the open end of the vagina is closed with catgut, silkworm-gut interrupted suture, or fine silk. The peritoneal retracted flaps are turned with their raw surfaces toward the vagina, and the sutures, closing the wound, embrace the edges of the vaginal ring and pass through both layers of the peritonæum. Any gaps in the broad ligament are closed with catgut running suture. The sponges are now removed; they are loaded with blood which has escaped from the mass, not from the general circulation. The peritoneal cavity is left clean. Not one bleeding point is allowed to escape observation and treatment. The abdominal wound is closed with through-and-through silkworm-gut sutures, three to the inch, if the patient is lean; but when layers of fat fully two to two inches and a half lie under the skin I do not attempt this method, but the

following: The peritoneum is closed with a running catgut suture. The aponeurosis and recti muscles are approximated with interrupted sutures, three to the inch, of carefully sterilized silkworm gut. The remaining tissues are approximated with heavy silk sutures, two to the inch, a silkworm-gut drain having first been laid along the entire length of the wound at the bottom of the fatty layer (Edebohls). The abdominal surface is now carefully sterilized with creolin solution. The wound is covered with aristol or iodoform; a gauze and cotton dressing, sterilized, and bandage complete the abdominal dressing. The patient is now lowered, her knees are brought up and in the lithotomy position, the vagina is washed out with sterilized hot water and lightly filled with iodoform gauze. So thus by ligation, cutting, enucleation, and vaginal drainage the operation is completed. There is practically no shock after the operation, and the highest temperature I have seen in the process of recovery was 100.4° F. The shortest period of convalescence has been fourteen days' confinement to bed. The longest has been twenty-one days-in a fat subject. In my first case I wounded the bladder, and the patient was here for two months after the operation before the bladder wound entirely healed; but barring this accident, which must be rare, the period of convalescence is about equal to that after ovariotomy.

In my last seventeen operations for the removal of fibroid tumors of the uterus, in every one of which I have removed the entire uterus or the uterus above the vaginal attachment, I have had sixteen recoveries and one death. Of these seventeen operations, eleven were done by Hegar's method, with one death. Of the remaining six, four were total ablations, as above described; all the patients recovered. One was after Baer's or Baldy's method; this patient also recovered. In one case I dropped the pedicle on something after Schröder's plan, and the patient recovered. These seventeen consecutive operations by four different methods have given a mortality of one, or less than six per cent.

#### ANTISEPTICS

IN SURGERY, GYN.ECOLOGY, AND MEDICINE.\*
By EDWIN R. MAXSON, M. D., A. M., LL. D.,
STRACUSE, N. Y.

Since Professor Joseph Lister, now Sir Joseph, demonstrated in the Royal Infirmary of Glasgow the beneficial effects of antiseptics in surgery, which I witnessed in 1867, there has been ample confirmation of their efficacy.

It was my report to an American journal, first submitted to him, that brought an early if not the first account of his observations to this country. And carbolic acid, one part, to five of boiled linseed oil, usually made into a paste or putty with whiting (a carbonate of calcium), was applied to suppurating, granulating, local diseased conditions, wounds, etc., as is well known.

This, of course, kept the air in the surgical wards charged with carbolic acid, and to an appreciable extent in

<sup>\*</sup> Read before the Syracuse Academy of Medicine, March 6, 1894.

the contiguous medical wards, alleviating, as it appeared to us, their non-surgical diseases also.

Since that time progressive surgeons the world over have quite generally resorted to antiseptics in some form in all septic surgical diseases, constituting the greatest advancement that has been made in surgery since it became a science, undoubtedly. And now, with the multitude of antiseptics at hand for internal and external use, the alleviation and cutting short of surgical disease are beyond computation, as our best practical surgeons can not fail to see in the healing of contused wounds, compound fractures, prevention of suppuration in thoracic, abdominal, and other perforations, operations on large joints, gunshot wounds, and a multitude of operations and conditions too numerous to mention here. Not only is the alleviation they afford of infinite value, but the cutting short of surgical diseased conditions is of still greater utility when the disease is even of a local character for which they are used.

Great, however, as the local use of antiseptics in surgery may be, their internal administration in preventing and curing blood-poisoning is also beyond all human computation, not only saving life, but also hastening the cure of the local disease at the same time. Hence the progressive, humane surgeon is no longer groping in forlorn darkness as to what should be done in all putrid surgical disease, local and general, as he did to a great extent before the introduction of antiseptic surgery. And it is a credit to surgeons that, though doubting at first, they have generally yielded to the dictates of common sense, and like "good Samaritans" are now preventing general sepsis by local antiseptics and curing general sepsis by administering general antiseptics, and thus aiding to cure local sepsis as well. Though by a proper selection and application locally, or by internal administration or both, as may be indicated, the good surgeon does not omit such other means as may be indicated to cure the disease; he feels, however, an assurance that whatever poison may have caused, or may be aggravating the disease, will be rendered inoperative, and he has only to resort to such other means as may be indicated to give the patient the greatest possible chance of a cure in the shortest possible time; and in just so far as they prevent and destroy the cause of septic conditions, local and general, is antiseptic surgery an advance in or improvement of the former treatment of surgical diseased conditions.

In Gynacology.—The same holds true in the surgical department of gynæcology, and perhaps to even a greater extent than in general surgery, in cases too numerous to mention here. And the gynæcologist who heeds the indications afforded by such cases is sure to have the approval of an enlightened conscience and also the gratitude of the better half of our divine humanity. Antiseptic gynæcology then should be religiously adhered to, both local and general, to give the least possible suffering and danger for the shortest possible time to mothers, wives, sisters, daughters, and maids, in a great degree subject to the chances of life and death, through wise, conscientious, and judicious antiseptic treatment of the diseases peculiar to them.

from unnecessary operations, always a matter of delicacy, especially to them; with antiseptic helps, local and general, the duration of treatment may be thus cut short to the least possible time, and the number of them rendered as few as may be consistent with life and health. And the judicious gynæcologist will never neglect such other measures as may aid in this very desirable result, I am sure.

In Medicine.- In general medical practice, including all septic and contagious diseased conditions, antiseptics are as efficacious in aborting, cutting short, and rendering milder the disease, as in surgical cases. Why not?

This has become too well established by leading physicians in this and other countries to be gainsaid, and in the near future intelligent common sense, progressive medical treatment will recognize and prompt to the use of antiseptics in septic and contagious diseases of every character as much as in surgical cases undoubtedly, with such other measures as may be indicated. But it takes time to bring about a radical change of such a character, involving the relinquishment of traditions in relation to what has been regarded as self-limited disease.

It has not formerly been duly realized that it is the poison or septic cause of contagious diseases that requires a limited time for the system to eliminate or throw off the offending cause, and hence it was supposed that some contagious diseases were self-limited in duration, and could not be aborted, or even cut short, by any treatment whatever. But observation and the exercise of common sense, with enlightened reason, have clearly demonstrated to those willing and able to break away from the fogvish fossils of the past that by early destroying the poisonous, septic, or contagious principle the system has little or nothing to eliminate; and hence, if the disease is not aborted in every case, it is cut short and rendered much lighter. This has been the testimony of many of our most substantial physicians in Europe and the United States during the past few years, and more are coming to know it by the best possible evidence-experience.

Having carefully watched this matter from its inception, first with Sir Joseph Lister, in the Royal Infirmary of Glasgow, as before stated, and since in a great variety and number of appropriate cases, I am prepared to emphatically add my testimony in favor of antiseptic treatment in septic and all contagious diseases that have fallen under my observation in an extensive general practice since 1867; by no means ignoring or neglecting such other measures as may be indicated in any case. But, in my experience, antiseptics very early, with warm drinks, warm foot baths, sinapisms, if needed, a mild alterative laxative, as an improved cathartic pill, as may be required, suitable nourishment, and a tonic, as cinchonidine, in two-grain (thirteen centigrammes) doses every six hours, alternating with the antiseptic, say two grains (thirteen centigrammes) of sulphocarbolate of sodium for adults, less for children, may very generally abort septic and such contagious diseases as have fallen under my observation. But in such cases, when neglected early, my observation has been that, though not aborted, they are materially cut short and rendered lighter by such antisep-I need not specify here the cases in which, abstaining I tic and tonic treatment; complications, of course, being

562

liable to occur, calling for wet or dry cups, blisters, etc., as the complications may indicate.

This applies to all non contagious septic diseases, including typhoid pneumonia, puerperal fever, erysipelas, dysentery, diarrhea, rheumatism, influenza (la grippe), and a multitude of others. And among contagious diseases I will only refer to varicella, parotiditis, diphtheria, rubeola, scarlatina, and enteric or typhoid fever, in all of which I have found so many cases, either aborted entirely or so far cut short and rendered milder, that I have entirely abandoned the fossil idea that there are any self-limited diseases among them, or, in fact, any others, provided a suitable antiseptic is selected and judiciously administered, early, with such other treatment as may be indicated as before described. And, while I have not treated smallpox to test antiseptics in that disease, Dr. Samayoa, of Guatemala, in Escuela de Medicina, recently reported like results in aborting, cutting short, and rendering lighter small-pox by hydrochloride of cocaine, a strong antiseptic. He states, after using this alkaloid in several cases of small-pox, his results were as follows:

"Cocaine, given continuously from the beginning, can completely abort the disease.

"If given after the eruption has appeared, it will transform confluent or hæmorrhagic into discrete forms.

"Sometimes when cocaine is given from the beginning of the disease the eruption assumes a corneal aspect and the pustules fall very soon.

"Cocaine prevents suppuration; hence there is no secondary fever, and no marks remaining on the skin.

"To obtain these results it is necessary to give the cocaine as soon as the initial symptoms appear, and it must be continued without interruption.

"The best preparation is the hydrochlorate, and should be continued five days, or even nine if necessary."—La Escuela de Medicina." \*

This is high authority and corresponds with my observations in the treatment of contagious diseases.

To accomplish this, however, in the diseases I have treated antiseptically, warm, plain, suitable food and hot drinks, as toast-water with milk, and at meal hours the same or weak tea and toast, should only be allowed, and no trash at any time, such as oranges, lemonade, or other drink than I have mentioned, and only gradually other food. And in enteric or typhoid fever, and in other diseases in which the alimentary, bronchial, or other internal mucous membranes or structures are primarily or become secondarily involved, sinapisms early, and, if not subdued, cups or even blisters may be required. The antiseptic should be continued till all the spores have germinated and been destroyed—one week at least after all symptoms of the disease disappear. For I am convinced that no safe antiseptic will destroy the spores before they germinate.

Among the antiseptics for internal use I oftener give the sulphocarbolate of sodium, as it is soluble, tasteless, and efficient; two-grain (thirteen-centigramme) doses for adults, less for children, in proportion to the age, in any 818 Madison Street.

SYMMETRICAL CONGENITAL DEFECTS IN THE ANTERIOR PILLARS OF THE FAUCES.\*

BY HUBERT DOUGLAS HAMILTON, B. A., M. D., LARYNGOLOGIST TO THE MONTREAL DISPENSARY.

It is desired here to put on record this somewhat rare malformation, noted by Dr. George W. Major.

J. C., aged twenty-five years, of the fire police, subject of laryngeal phthisis. Referred by Dr. William A. Molson for local treatment on December 8, 1890. (No. 2,048 in Register of Department of Diseases of Nose and Throat, Montreal General Hospital.)

On examination, the anterior pillars of the fauces present two longitudinal slits or fissures, the left being slightly the larger, and measuring half an inch in length by about three sixteenths of an inch in width at the widest part.

These openings are of a somewhat oval form, extending down to the sides of the base of the tongue.

As the tonsils are deficient, the condition is very easy of observation. There are no evidences of cicatricial tissue anywhere, the edges of the openings being smooth, and presenting the natural appearances of the surrounding parts.

These cases are interesting as curiosities, and a knowledge of them is important in diagnosticating from other affections. Max Toeplitz, of New York, reports a case in the Archives of Otology for January, 1892, and states that the literature of the subject contains six similar observations up to that date.

The cases so far recorded have been by Wolters in 1859 (Zeitschrift f. rat. Medic., dritte Reihe, Bd. vii, p. 156).

J. Solis-Cohen, in the Medical Record (July 20, 1878, p. 45), and in the second edition of his work on Diseases of the Throat (p. 206). This writer maintains that a separate investment of the fibers of the palato-glossus muscle is the cause of the condition.

Lefferts reports a case in the Philadelphia Medical News (January 7, 1882), besides communicating privately with Toeplitz regarding two unpublished cases in 1890.

Chiari, a case in 1884 (Monatschr. f. Ohrenheilk., Jahrg. xviii, 1884, No. 8, Aug., p. 140).

Schapringer, a case in the same year (Monatschr. f. Ohrenheilk., No. 11).

Besides these cases of symmetrical defects, observations have also been made upon unilateral malformations of the anterior pillars by Schapringer, Claiborne (American Journal of the Medical Sciences, April, 1885, p. 495), and Toeplitz (Archiv. of Otol., January, 1892, p. 89).

139 Metcalfe Street.

ordinary septic or contagious disease, given every six hours, may be sufficient, as a rule. Locally, boroglyceride and ichthyol are favorites with me. I never use quack nostrums, antiseptic or other. In addition to the antiseptic, non-toxic to the patient, when a tonic is indicated, such as are also antiseptic should be preferred, and the use of antiseptics should never be to the exclusion of other measures indicated.

THE

## NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by D. Appleton & Co.

Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 5, 1894.

#### CONGENITAL HEART DISEASE IN CHILDREN.

In the Journal de clinique et de thérapeutique infantiles for April 12th there is an article on the diagnosis of congenital affections of the heart in children, by Dr. G. Variot. The author divides these affections into two great groups, according as they are accompanied by cyanosis or not. Cyanosis, he says, is a symptom of such capital importance that on the strength of its existence alone we may make a positive diagnosis of malformation of the heart. The auscultatory signs which co-exist are inconstant and too untrustworthy, he says, to admit of the exact determination of the congenital lesion; therefore they should be considered secondary in eyanotic children. On the other hand, in congenital affections of the heart without cyanosis, physical exploration of the heart by inspection, palpation, percussion, and above all auscultation is the leading resource, often indeed the only one on which we can base a substantial diagnosis. The functional troubles which may be taken into account as symptoms, as revealing indications, are so slight as to pass unperceived until we practice auscultation and discover a lesion previously as latent for the patient as for others.

When, he continues, without any acute or chronic disease of the respiratory passages and without signs of asphyxia, we find continuous cyanosis in a child, we may affirm at once that it is the subject of a congenital lesion of the heart. The existence of a congenital lesion with cyanosis unaccompanied by any abnormal murmur is not very exceptional. The absence of such a murmur has been distinctly noticed by Peacock, Goodbart, and various French physicians. The variability of the auscultatory signs in children affected with congenital cyanosis is such that these signs ought to be relegated to a secondary position. and indeed it is rarely practicable, according to the best observers, to make use of them when they exist for distinguishing various malformations. Given, then, a well-marked case of cyanosis, what is the most probable congenital lesion, proper reserve being understood? According to Peacock, whose anatomical and clinical writings on anomalies of the heart are generally accepted, congenital lesions present themselves in the following order of frequency and gravity: 1. Stenosis of the pulmonary artery. 2. Stenosis of the pulmonary artery and persistence of the foramen ovale. 3. Stenosis of the pulmonary artery and imperfect separation of the ventricles. 4. Atresia of the pulmonary artery. 5. The existence of only one ventricle with one or two auricles. The two last-named lesions are very exceptional and rarely allow of prolonged survival. Theoretically, they must always be taken into consideration, but, practically, they may be disregarded.

The first three lesions remain. Stenosis of the pulmonary artery is not habitually complicated with cyanosis. The persistence of Botal's foramen with stenosis of the pulmonary artery has frequently been encountered unaccompanied by cvanotic signs. But the intraventricular perforation with stenosis of the pulmonary artery is invariably accompanied by cyanosis. This latter lesion is supposed to exist in a large majority of cases of congenital cyanosis. It is not impossible for a persistence of Botal's foramen or an unclosed ductus arteriosus to be found at the same time, but these two last anomalies have no characteristic physical signs by which they may be revealed. Congenital lesions of the heart with cyanosis in children are ordinarily latent. It is by chance auscultation, if the expression may be allowed, says the author, that they are nearly always discovered. A systolic souffle, with a maximum intensity at the pulmonary orifice, is not, however, always pathognomonic of stenosis of the pulmonary artery. Goodhart observed the same physical signs in connection with dilatation of the pulmonary artery following a premature and prolonged atelectasis impeding the depletion of the right ventricle and consequently of the pulmonary artery. He reports a very exceptional anomaly of the aorta, consisting in stenosis situated below the subclavian artery. This stenosis, more or less marked, may be replaced by a complete obliteration of the aorta. If there is only stenosis, a systolic souffle can be ascertained, also, at the same time, dilatation of the branches of the subclavian artery, which serve to establish collateral circulation. Essential mitral stenosis is more frequently found in women, and, since Peacock's researches, it has commonly been classed among congenital affections of the heart.

#### ADAPTATION IN THERAPEUTICS.

Perhaps one of the most striking advantages that can accrue to a general practitioner by observing the methods of a specialist, or to a specialist by giving attention to the procedures of those engaged in other specialties than his own, is the guidance to adapting to his own work the devices which he sees fall into use with greater precision than he would be likely to attain if he contented himself with reading, reflection, and association exclusively with those of his own class. This is more particularly true of topical medication. The ophthalmologist is almost sure to show to a practitioner who follows his work some special application to the eye which the observer may turn to good account in the medication of other organs of the body. The same is true of the otologist, the rhinologist, the laryngologist, the dermatologist, the gynæcologist, and so on.

It is seldom that an opportunity to carry on this advantageous observation beyond one's own territory, this sort of reconnaissance, so to speak, is presented on so large a scale and with such capabilities of variation as when a number of special societies meet in the same town at one time, as is the case on the occasions when the Congress of American Physicians and Surgeons assembles. It is almost as much on this account as by reason of the attractive programme provided for the general

sessions of the congress that we again urge upon our readers the advantage of attending the approaching sessions of that body and of its constituent organizations, to be held in Washington on the 29th, 30th, and 31st of this mouth and the 1st of June. To draw inspiration from these meetings it is not necessary that one should be a member of any of the societies that go to make up the congress; any practitioner may avail himself to the utmost of the opportunities that will be lavisbly presented of bettering himself in therapeutic acquirements, to say nothing of improving himself in diagnosis and all the other accomplishments that go to make a successful physician or surgeon.

#### MINOR PARAGRAPHS.

#### GUAIACOL IN THE TREATMENT OF BLENNORRHAGIC EPIDIDYMITIS.

AT a recent meeting of the Société médicale des hôpitaux, of Paris, a report of which we find in the Union médicale for April 10th, M. Balzer and M. Lacour stated that they had obtained excellent results in the treatment of blennorrhagic epididymitis with guaiacol. On the skin of the inguinal region, they said, pure guaiacol could be applied; on the scrotum it was better to employ an ointment of from two to five parts of guaiacol to thirty of vaseline. One of the first effects of the application of this ointment was a rather sharp burning, lasting for about ten minutes; then the patient felt a sensation of heat, and almost immediately the pain disappeared, at least for three or four hours, and sometimes it did not return. Ordinarily it was necessary to make two applications on the first day, but after the third day there was no longer any pain. The applications were then discontinued, for they did not seem to exert any very decided resolvent action upon the inflammatory infiltration of the epididymis. It was evident, the authors said, that guaiacol exerted a very clear and energetic effect upon the pain of the disease; moreover, it overcame certain of the general symptoms which were due to the pain, for example, sleeplessness. It gave rise to a slight erythema of the scrotum, followed by drying and exfoliation of the epidermis. The authors had treated twenty cases with guaiacol, and in all of them the results had been most favorable and very rapid.

#### THE DENISON INHALER.

We have been favored by the manufacturers, the Denver Surgical Instrument Company, with two samples of a most ingenious inhaler devised by Dr. Charles Denison, of Denver, and called by him the "air-pressure inhaler and exhaler." By a clever arrangement of passages of influx and efflux for the air breathed through it, which can be so adjusted in capacity as to restrict or facilitate the current in either one of them independently of the other, the air-pressure within the lungs can be controlled. In a little chamber through which the current of air passes one can place a small absorbent packet moistened with any liquid of which it is desired that the vapor should be inhaled. The apparatus is made of hard rubber. It is light and of a convenient size for carrying in the pocket.

#### THE COUNTY MEDICAL SOCIETY'S DETECTIVE WORK.

THE Medical Society of the County of New York undertakes to assist in the enforcement of the laws governing medical practice by seeking out and prosecuting offenders. One of its agents

has lately been represented before the public as having acted the part of a go-between for ill-informed midwives and the utterers of certain certificates purporting to license them to practice. The society has investigated the matter and, while it does not find that any illegal acts have been performed by its agent, it has concluded that his course has been ill advised and that it is well to dispense with his further services.

#### THE PHYSICAL EXAMINATION LAW.

SOMEWHAT more than two months ago we chronicled a judicial order for the physical examination of a young woman who had brought suit against a railway company to obtain damages for bodily injury. We expressed our disapproval of the law under which the order was issued, and not altogether on sentimental grounds. The order was afterward reversed by a higher court, and now it is announced that the Court of Appeals has sustained the reversal.

#### THE DOMESTIC FOWL AS A SURGEON.

In a recent number of the Lyon médical there is a summary of an account, given in the Mouvement médical and afterward in abstract in La Médecine moderne, of a case in which a chicken was suffocating as the result of too great haste in attempting to swallow a piece of bread. The cock, grave and majestic, stalked up, threw a side glance into the throat of the distressed chicken, then placed himself face to face with her and plunged his beak into her mouth, whence he withdrew a large piece of bread. The success of the operation was testified to by the operator and the patient crowing and cackling in concert.

#### THE ABSORPTION OF IODINE BY THE UTERUS.

In the Centralblatt für Gynäkologie for April 14th there is a summary of an account, published in the Revue médicale de la Suisse romande, of a case in which toxic effects were observed within ten minutes after cauterization of the canal of the cervix uteri with tincture of iodine; also of the case of a woman who had goître, and, being unwilling to undergo the iodine treatment of the tumor, was treated by frequent applications of tincture of iodine to the cervical canal on account of some disease of that part. The goître soon began to grow smaller.

#### THE DEMAND FOR LOYALTY IN A PHYSICIAN.

A RECENT number of the *Progrès médical* contains an announcement to the effect that a town of six thousand inhabitants is in need of a physician. It is stated that the locality is very desirable, and that the physician must be young, capable, industrious, and a supporter of the Republic.

#### ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending May 1, 1894:

DISEASES.	Week end	ing Apr. 24.	Week ending May 1.			
DISEASES.	Cases.	Deaths.	Cases.	Deaths.		
Typhoid fever	130	14 14 1 1 16	6 147 0 239	0 11 0 14		
Diphtheria	170	63	202 16	50 5		

The Wisconsin State Medical Society held its forty-eighth annual meeting in Milwaukee on Wednesday, Thursday, and Friday of this week, under the presidency of Dr. B. C. Brett, of Green Bay. The programme included the following titles:

An Address in Surgery, by Dr. H. Reineking, of Sheboygan; Tubercular Affections of the Knee Joint, by Dr. W. Mackie and Dr. H. M. Brown, of Milwaukee; Injuries of the Cranium and Contents: Diagnosis by Dr. B. G. Gudden, of Oshkosh; Treatment by Dr. W. H. Earles, of Milwaukee; Medico-legal Aspects by Dr. J. A. Jackson, of Madison; Hernia-Anatomical Considerations, by Dr. F. W. Epley, of New Richmond; The Treatment of Reducible Hernia, by Dr. B. T. Phillips, of Menomonee, Mich.; The Treatment of Strangulated Hernia and its Radical Cure, by Dr. A. H. Levings, of Milwaukee; Splints, by Dr. G. D. Ladd, of Milwaukee; Varicose Veins and their Treatment, by Dr. J. R. Minahan, of Green Bay; The Local Treatment of Acute Follicular Amygdalitis, by Dr. A. B. Farnham, of Milwaukee; The Internal Treatment of Acute Follicular Amygdalitis, by Dr. W. H. Neilson, of Milwaukee; Removal of the Tonsils, by Dr. Joseph Szoldrski, of Milwaukee; The Ætiology, Pathology, and Symptomatology of Tonsillar Hypertrophy, by Dr. F. C. Rogers, of Milwaukee; Tumors of the Tonsils, by Dr. O. M. Waterman, of Milwaukee; The Pathology of Granular Conjunctivitis, by Dr. H. V. Würdemann, of Milwaukee; The Medical Treatment of Granular Conjunctivitis, by Dr. C. Zimmermann, of Milwaukee; The Surgical Treatment of Granular Conjunctivitis, by Dr. J. A. Bach, of Milwaukee; The Complications of Granular Conjunctivitis and their Treatment. by Dr. E. H. Neymann, of Milwaukee; Acromegalia, by Dr. E. L. Bullard, of Waukesha; Pyrexia, by Dr. W. H. Washburn, of Milwaukee; Antipyretics and their Modus Operandi, by Dr. T. H. Hay, of Milwaukee; The Present Status of the Treatment of Acute Febrile Diseases by means of Antipyretic Drugs, by Dr. H. B. Sears, of Beaver Dam; Hyperpyrexia and its Management, by Dr. G. M. Steele, of Oshkosh; The Ephemeral Pyrexiæ of Childhood, by Dr. H. B. Tanner, of Kaukauna; The Pathology of Uramia, by Dr. B. J. Bill, of Genoa Junction; The Clinical Aspects of Uramia, by Dr. E. H. Townsend, of New Lisbon; The Therapeutics of Uræmia, by Dr. C. H. Lemon, of Milwaukee; The Principles and Ruts of the Practice of Medicine, by Dr. J. R. Currens, of Two Rivers; Stomach Catarrh and Lavage Treatment, by Dr. A. F. Heising, of Menomonee; Waiting, by Dr. S. W. French, of Milwaukee; The Country Doctor in Obstetrics, by Dr. W. T. Sarles, of Sparta; Hystero-myomectomy, by Dr. A. J. Puls, of Milwaukee; Observations on Seventy Recently Performed Laparotomies, by Dr. F. B. Robinson, of Chicago; Complications in Abdominal Surgery, by Dr. A. J. Burgess, of Milwaukee; Perineal Repair, by Dr. P. O'Keef, of Oconto; Strophanthus, by Dr. D. Mereness, of Milwaukee; The Use of Heart and Respiratory Stimulants in Anæsthesia, by Dr. H. M. Fisk, of Wauwatosa; The Use of Heart Tonics and Stimulants in Acute Febrile Diseases, by Dr. C. M. Gould, of Superior; The Treatment of Malignant Diphtheria, by Dr. S. P. Deahofe, of Mineral Point: Belladonna, by Dr. S. B. Sperry, of Milwaukee; House Disinfection, by Dr. O. T. Hougen, of Grand Rapids; The Duty of the State toward the Inebriate, by Dr. R. M. Wigginton, of Waukesha; The Hygiene of Villages, by Dr. L. H. Pelton, of Waupaca; Heredity and the Wards of the State, by Dr. E. H. Townsend, of New Lisbon; Provision for the Insane awaiting Commitment, by Dr. M. J. White, of Wauwatosa; Functional Nervous Diseases, by Dr. I. M. Wiltrout, of Hudson; Some Remarks on Disinfection of Baggage and Merchandise in Relation to Cholera, by Dr. Walter Kemster, of Milwaukee; The Treatment of Epilepsy, by Dr. W. F. Wegge, of Winnebago; Report of Two Cases of Unusual Parasitic Intestinal Disease, by Dr. E. F. Woods, of

Janesville; Croupous Pneumonia in Children, by Dr. J. Noer, of Stoughton; Catarrhal Pneumonia, by Dr. Julia P. Kelley, of Milwaukee; Cerebral Signs and Stimulations in Pneumonia, by Dr. J. R. Barnett, of Neenah; Gouty Deposits of the Testicle, by Dr. F. J. Tower, of Milwaukee; Infantile Cyanosis from Bismuth Poisoning, by Dr. A. S. Maxson, of Milton Junction; The Treatment of Opium Poisoning, by Dr. W. H. Hulburt, of Reedsburg; Ocular Affections in Syphilis of the Brain, with Report of Five Cases, by Dr. C. Zimmermann, of Milwaukee; Hæmophilia, with Report of Case, by Dr. H. A. Anderson, of Pine Bluff; The Importance of Surgical Treatment of Otitis Media Purulenta, by Dr. G. E. Seaman, of Milwaukee; A Few Remarks about Water, by Dr. A. J. Hodgson, of Palmyra; and the president's annual address.

The New York Post-graduate Medical School and Hospital.—The new building, on the corner of Second Avenue and East Twentieth Street, will be opened on Tuesday afternoon and evening, the 8th inst. The exercises will occupy the time from 2 to 6 and from 8 to 10 P. M.

The Medico-legal Society.—At the next meeting, on Wednesday evening, the 9th inst., Dr. H. W. Mitchell will read a paper on Medical Witnesses, and Mr. Clark Bell will read one on Railways and Railway Surgeons.

The Association of Military Surgeons of the United States.—The association's fourth annual meeting, held in Washington this week, had the advantage of very commendatory words from President Cleveland, who opened the meeting.

The Medical Department of the University of the City of New York held its fifty-third annual commencement on Tuesday evening, the 1st inst.

The Society of the Alumni of St. Luke's Hospital held its annual meeting on April 24th and elected the retiring officers to serve another year.

The late Dr. Albert C. Stanard.—At a recent meeting of the Harvard Medical Society the following preamble and resolutions were passed:

Whereus, Dr. Albert Cushman Stanard, an esteemed member of the Harvard Medical Society of New York, has in the infinite wisdom of God been called thus early to lay aside the duties of life, cut down in the vigor of early manhood, as the paths of usefulness and promises of prosperity were opening wide to him; therefore be it

Resolved, That in his untimely death we recognize the loss to the society of one of its most promising and worthy members and desire to pay to his memory a tribute of sincere respect.

Resolved, That we extend to his stricken sisters our heartfelt sympathy at the grief which has come upon them.

Resolved, That these resolutions be published in the New York Medical Journal.

[Signed.]

JOHN B. WALKER.
WILLIAM B. COLEY.
JOHN H. HUDDLESTON.

The Middleton Goldsmith Lecture was delivered before the New York Pathological Society by Dr. William H. Welch, of the Johns Hopkins University, Baltimore, on Saturday evening, April 28th, on the subject of Mixed and Secondary Infections.

Changes of Address.—Dr. H. J. Boldt, to No. 54 West Fifty-first Street; Dr. Andrew F. Currier, to No. 138 Madison Avenue; Dr. George T. Elliot, to No. 14 West Thirty-third Street; Dr. Ramon Guitéras, to No. 23 West Fifty-third Street; Dr. C. E. Lockwood, to No. 34 West Thirty-eighth Street; Dr. R. K. Macalester, to No. 23 West Fifty-third Street; Dr. Frederic E. Sondern, to No. 38 West Thirty-eighth Street.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 21 to April 28, 1894:

HAVARD, VALERY, Major and Surgeon, is relieved from duty at Fort D. A. Russell, Wyoming, and ordered to David's Island, New York, for duty at that depot, relieving Gibson, Joseph R., Major and Surgeon. Major Gibson, on being relieved by Major Havard, is ordered to Fort Snelling, Minnesota, for duty at that station, relieving Winne, Charles K., Major and Surgeon. Major Charles K. Winne, on being relieved by Major Gibson, is ordered to duty at Fort McHenry, Maryland, relieving Ewing, Charles B., Captain and Assistant Surgeon. Captain Ewing, on being relieved by Major Winne, will report for duty at Jefferson Barracks, Missouri.

Kneedler, William L., Captain and Assistant Surgeon, will, in addition to his present duties as post surgeon at Fort Mason, California, perform that of attending surgeon at San Francisco, Cal., until further orders.

GLENNAN, JAMES D., Captain and Asistant Surgeon, is granted leave of absence for one month, to take effect on or about April 24, 1894.

Marine-Hospital Service.—Official List of the Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service for the Five Weeks ending April 21, 1894:

MURRAY, R. D., Surgeon. To inspect quarantine stations of Florida. April 17, 1894.

Bailhache, P. H., Surgeon. To proceed to New London, Conn., as inspector. April 18, 1894.

Mead, F. W., Surgeon. To report to the chairman of the Committee on District of Columbia of the United States Senate for special duty. April 7, 1894.

CARMICHAEL, D. A., Passed Assistant Surgeon. To report to the medical officer in command at San Francisco, Cal., for temporary duty. April 11, 1894. To proceed to Fort Townsend, Washington, and inspect Marine-Hospital Service and quarantine service. April 1, 1894.

BROOKS, S. D., Passed Assistant Surgeon. To proceed to Chicago, Ill., for temporary duty. April 3, 1894.

Bratton, W. D., Passed Assistant Surgeon. To report at bureau. April 16, 1894. To proceed to Reedy Island Quarantine and await orders. April 20, 1894.

VAUGHAN, G. T., Passed Assistant Surgeon. Detailed as chairman of the board for physical examination of candidates for the Revenue Marine Service. March 19, 1894.

Cobb., J. O., Passed Assistant Surgeon. To proceed to Seattle and Tacoma, Wash., as inspector. April 12, 1894.

WERTENBAKER, C. P., Passed Assistant Surgeon. Granted leave of absence for two months. April 3, 1894.

Brown, B. W., Assistant Surgeon. Granted leave of absence for six days. April 7, 1894.

Decker, C. E., Assistant Surgeon. Placed on "waiting orders." April 1, 1894.

STRAYER, EDGAR, Assistant Surgeon. To proceed to Vineyard Haven, Mass., for temporary duty. April 4, 1894.

Oakley, J. H., Assistant Surgeon. To proceed to San Francisco Quarantine Station for temporary duty. April 11, 1894.

PROCHAZKA, EMIL, Assistant Surgeon. To proceed to Cleveland, Ohio, for temporary duty. April 2, 1894.

#### Society Meetings for the Coming Week:

Monday, May 7th: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society (private), New York; Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; Boston Medical Association (annual); St. Albans, Vt., Medical Association; Providence, R. I., Medical Association; Hartford, Conn., Medical Society; South Pittsburgh, Pa., Medical Society; Chicago Medical Society.

Tuesday, May 8th: National Association of Railway Surgeons (first day, Galveston); New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); Kings County, N. ## Proceedings of Societies.

PHILADELPHIA ACADEMY OF SURGERY.

Meeting of April 2, 1894.

The Vice-President, Dr. John B. Roberts, in the Chair.

Freedom from Recurring Appendicitis after Evacuation of the Abscess and Retention of the Appendix.—Dr. James M. Barton read a paper with this title. He said that at the

last meeting of the American Surgical Association he had reported nine recoveries from operations for appendicitis in which the appendix had not been removed. These had all been cases of ruptured appendix with circumscribed abscess, with no general peritonitis and no symptoms of obstruction.

The operation had consisted in opening the abdomen and using sterilized cheese-cloth to hold the movable intestines back and to protect the general peritoneal cavity while the abscess was opened and emptied. Drains were then introduced, some of the cheese-cloth was permitted to remain, and most of the wound was closed. No attempt was made to find or remove the appendix.

Before considering the eventual condition of the appendix in these cases he wished to report, briefly, five more cases in which he had operated in the same manner, in all of which the patients had recovered. Brief statements of the leading features of the cases were then made.

His object in bringing this subject up was to exhibit several of these patients and to read reports from most of the others to show that none whose histories he had been able to follow had been at all troubled by the retained appendix, and to learn if the experience of the fellows of the academy had been similar to his own.

It was becoming widely recognized that this method of operation was accompanied by a low rate of mortality. Richardson in this country, Tait in England, and Reclus and Schmidt on the Continent, as well as many others, contented themselves in these cases of local purulent peritonitis with protecting the peritoneal cavity and draining. Others, however, still considered that no operation was complete without removing the appendix. In the March number of the Annals of Surgery, Dr. Fowler advised, in these cases, the removal of as much of the appendix as could be removed without separating adhesions, but considered it necessary to remove the rest of the appendix at a second operation.

Of these fourteen cases, in eleven he had operated during the last two years. All on whom he had operated in this manner had recovered, and none, that he was aware of, had had any trouble with the retained appendix since.

As the mortality had been much greater when he had removed the appendix, he now rarely did so unless the appendix was unruptured, or, if it was ruptured, only when general peritonitis had occurred.

Of these eleven patients he had been able to follow the history of eight, several of whom were present for examination.

The three whom he had not been able to find were hospital patients; two of them had been brought to the hospital by physicians. If either of these had had a recurrence needing surgical aid he would probably have known of it.

Of the eight whose histories he had been able to follow, none had had the slightest symptom referable to the appendix since the operation. No tumor was to be felt, and there was no tenderness. Indeed, they all appeared to have been singularly free from diseases of all sorts since the operation.

From the uniformity with which full and complete recovery had occurred in the few cases that had come under his care, it looked as if the appendix was not very apt to give trouble if permitted to remain. Indeed, he thought it was quite likely, in cases such as he had been considering, that the opening from the appendix into the intestine was closed early in the attack—closed quite as firmly as any ligature would close it—and there was but little probability that fæcal matters would ever again be able to enter the appendix either to cause a fæcal fistula to follow the operation or to start another appendicitis in the future.

If it was not firmly closed, the pus would never have broken through the walls of the appendix, or, having broken through, the resulting abscess would not have increased in size, but would have emptied itself through the appendix into the bowel.

To further illustrate the strength of this obstruction at the base of the appendix he had observed in several cases where fæcal fistula had followed appendicitis, that in none did the fæces make their exit through the appendix, but through other portions of the intestines, showing that the inflammatory deposit closing the appendix was even stronger than the healthy bowel.

The mortality following operations for appendicitis was mainly due to general septic peritonitis and to intestinal obstruction.

If we looked into the cavity of a fully developed abscess, such as he had been considering, we could readily see how these complications might follow the search for or removal of the appendix. The cavity of the abscess was lined with a thick layer of grayish, poorly organized, aplastic lymph filled with micro-organisms. The appendix lay buried beneath this lymph, and its cavity communicated freely with the general abscess cavity. The opening could occasionally be seen, and was often the only guide by which the position of the appendix could be recognized.

To tear up this fragile and infected lymph and distribute it through the peritoneal cavity while searching for and liberating the appendix would greatly increase the probability of establishing a general septic peritonitis.

Intestinal obstruction following operations for appendicitis was probably due to kinking of the recently separated intestines. As they reunited, covered and stiffened as they were by inflammatory deposits, they could not adjust themselves as readily as at the first formation of the abscess.

To avoid any misunderstanding he would state that it was only in cases of circumscribed abscess that he had been permitting the appendix to remain.

When the appendix was still unruptured, or when it had ruptured and general peritonitis had occurred, or when obstruction was present, he was in the habit of removing it.

Dr. Orville Horwitz had had the pleasure of assisting in several of the cases reported. Three months before he had operated in a case of appendicitis with circumscribed abscess. It was impossible to find the appendix without an extensive search. He therefore opened the abscess and packed the wound. The patient made an excellent recovery without any trouble.

Dr. John B. Roberts said that in cases where he did not expect to remove the appendix he had cut through the side and behind the peritonæum entirely. He thought that in this way there was less liability of infection of the peritonæum.

Dr. Thomas R. Nellson said that two years before he had assisted one of his colleagues at the Episcopal Hospital in a case of appendicitis where the abscess was post excal. The incision was first made in the usual position, but he suggested that it be closed and another incision made in Petit's triangle, so that good drainage would be secured. This was done and the patient made a good recovery.

In a patient nine or ten years of age, with a large collection of pus, post-caecal, he had opened and drained, and subsequently, when the health had improved, he had operated from the front and removed the appendix. The patient was now entirely well.

Another case was that of a man fifty years of age, who had had appendicitis the summer before last, and practically a self-opened abscess. Last winter he had come to the speaker with

a sinus leading to this pus cavity. With the knowledge that he had then had he thought that the best thing was to drain from the back, which he had done. The result was that the posterior opening had closed and the anterior had closed for a time and then reopened. A month ago the patient had returned and he had removed the appendix. The appendix had been cut in two by ulceration.

He had had several cases in which he had followed the practice of not attempting to search for the appendix in a condition of acute abscess. He thought that the trend of all writing on this subject was in the direction of what Dr. Bartony had suggested—namely, not to search for the appendix at the risk of breaking down the wall of lymph and giving a chance to microbes. He had seen two patients so treated. One, who was in excellent general health, came back with pain in the iliac region, but this was traceable to indiscretion in diet. He was confident that the adhesions surrounding the abscess must, in the long run, lead to more or less trouble. It was, however, safer to leave the appendix alone, and if it did-not cause further trouble it would be bad surgery to disturb it.

Dr. W. W. Keen would mention a case illustrating the danger of removing the appendix in some cases and also the need of prompt action. He had seen that morning a young man who. two years and a half before, had had a vague attack which must have been one of appendicitis. Fifteen months ago he had had a second attack, and five months ago yesterday the present illness had begun after a very hearty meal. He had recovered after some two or three weeks, but still had a little pain in the right iliac fossa. Eight days ago he was seized with a prostrating illness, with a temperature of 103°. When the speaker saw him he was wasted to an extreme degree and sweating, with contracted pupils from opium, and in a state of most profound sepsis. The abdomen was flat on percussion in the lower segment and very tympanitic from two inches above the pubes upward. The speaker opened the abdomen in the middle line, and a large quantity of fœtid pus mingled with gas escaped. With his finger in the cavity he could reach nearly to the anterior superior spine of the ilium on the right side and half-way to the spine on the left side. He did nothing but introduce two drainage-tubes and make a counter-opening at the extreme right border and pass a piece of gauze drain. To search for the appendix in such a case would be most unwise.

Dr. Roberts said the difficulty was to decide in what cases to operate and in what cases not to operate. Two months before he had seen a man in the country with a history of appendicitis two months previously. He had a well-marked lump in the right side of the abdomen, with a normal temperature. He could flex the thigh without pain. From the symptoms and the history, he thought that the case was going on rapidly to a cure and did not recommend operation. He had heard nothing from the case for a month, when the physician came and stated that there was a swelling in the groin. He found an abscess burrowing down from the appendix into the inguinal region. He opened the cavity and inserted a drainage-tube and washed it out. He had heard that the man was improving, when again the physician came, stating that the man had had a chill and that a large amount of pus had been discharged from the opening. He then had the patient brought to the city. He reopened the original wound and made a new opening above, and found pus burrowing up around the kidney and down into the groin, entirely extraperitoneal. He simply laid everything open and made a wound six inches long, which he stuffed with gauze. This was a case in which, when he originally saw it, there seemed to be no reason for operating, yet it went from bad to worse.

He felt inclined, as a rule, not to search for the appendix if there was a large abscess. In some cases he preferred to make the opening in the lateral aspect and drain in that way. Whether or not these cases were permanently cured, he was unable to say.

Dr. Keen said that, as a rule, he removed the appendix. He thought that it was bad surgery to leave the appendix unless the adhesions were very marked and could not be separated without the risk of harm. Where there was liability of breaking into the general peritoneal cavity he would not search for the appendix. Where there was a tumor he would make the incision over the tumor. He thought that we should not open the peritoneal cavity. It was rare to have an appendicitis going on to a condition of distinct tumor without pus being present. He would rather operate before any appreciable tumor had formed. In cases of tumor he almost invariably operated, even with a normal temperature or a declining temperature.

Dr. Orville Horwitz said there was one symptom which he thought aided in the diagnosis of pus, and that was pain down the thigh, especially on motion.

The Surgical Relations of the Thoracic Duct in the Neck, with the Exhibition of Two Dissections made by Mr. Ward Brinton.—Dr. John II. Brandon read a paper with this title. He showed dissections illustrating the two most common terminations of the thoracic duct. He had always supposed that the anatomical relations of the ending of this duct were not more abnormal than those of any other duct or vessel in the body. But, from the study of several dissections, and especially from the comparison of the descriptions given by various anatomical writers, he found great diversity in this respect. The general law was that the duct discharged its contents into the great veins, jugular and subclavian, at the base of the left side of the neck. This was done in several ways.

In the first of these dissections made by Mr. Brinton there was the regular or normal type, the duct curving over the apex of the pleura and terminating exactly in the angle formed by the junction of the subclavian and internal jugular veins. In the second dissection we found the duct dividing into two branches, which formed a circle by their union above. From this circle one trunk arched outward and divided into three branches. Two of these emptied into the subclavian at the distance of a quarter and half an inch from the internal jugular. Between these divisions passed a communicating branch. A large branch was also given off from the right side of the circle. This passed upward, turned to the left, and, deeply seated, crossed the neck transversely. The last portion of this branch was uninjected.

From the examination of these dissections the two typical terminations of the thoracic duct as described by Meckel could be studied. In most cases it emptied into the angle of union of the internal jugular and subclavian veins by one trunk; when more than one trunk existed the terminations of the thoracic duct were in both the internal jugular and subclavian veins. The duct, as stated by this observer, rarely opened into only one of these two veins.

In Quain's Anatomy it was stated that the thoracic duct often divided into two or three branches, which terminated separately in the great veins, as in the second dissection shown. Sometimes these several ducts again united in a common trunk, and occasionally one of the branches might pass across and empty into the veins of the right side of the neck. The duct had also been known to terminate in the azygous vein. According to Sappey, there were many varieties of termination; Professor Harrison Allen, in his Treatise on Anatomy, stated that the thoracic duct might empty into the jugular, the azy-

gous, or the left innominate vein; infrequently it might be double. Sometimes as many as six terminal vessels were present, which were received into the subclavian, jugular, vertebral, and axillary veins.

The irregular terminations of the thoracic duct were alluded to by Henle and by Breschet. The latter, in his Système lymphatique, described minutely the many varieties, and instanced one case, cited by Haller from Bartholin, of the communication of a duct branch with the vena cava.

The formation of circles, or insulæ, as seen in the specimen shown, was also referred to. The multiple termination of the duct was frequently met with in animals.

Hyrtl, so accurate and practical, told us that the varieties of termination of the duct were very numerous, and did not in the least interest the practical surgeon. He could not but think that the latter remark was too sweeping, especially in cases where any portion of an arch formed by irregular terminal branches reached high into the neck. If drawn upon or stretched by contracting and indurated tissues, or during an operation, it might easily be cut or torn. In an instance where a duct branch passed transversely for a considerable distance to empty into the subclavian vein, it certainly might readily be endangered. It seemed to him, therefore, that the possibility of irregular and manifold endings of the thoracic ducts must be considered by the practical surgeon, and that in operating in this deep-seated, dangerous region he should bear in mind its recognized abnormities.

That he had not overrated the chances of accident to the thoracic duet and its terminations would, he was sure, be evident on the presentation of the next paper, by Professor Keen.

Operation Wounds of the Thoracic Duct in the Neck, with a Resume of the Two Prior Recorded Cases and Two Additional Cases .- Dr. W. W. KEEN read the following paper: When we consider the frequency with which operations are done on the left side of the neck in the vicinity of the junction of the jugular and subclavian veins for the removal of enlarged glands, for tumors, for goitre, etc., and of stab and other wounds, it is surprising that there are not a number of instances of wounds of the thoracic duct. The danger of wounding it may be greatly increased by the fact that Dieterich (Henle's Anatomy, 1876, iii, 453) has found the arch of the duct as much as five centimetres and a half (over two inches) above the top of the sternum and touching the thyreoid gland. Yet, so far as my investigations have gone, I have only been able to discover two cases of wound of the cervical portion of the duct reported in surgical literature. To these to-night I add two more, one of my own and another the notes of which have been kindly furnished me by Dr. A. M. Phelps, of New York.

Even in war, wounds of the duct in any part of its course are practically unknown. In neither the Italian war of 1859, the Crimean war, nor our own late civil war, is there a single instance recorded.

Case I (Cheever's case).—Dr. Cheever reports in the Boston Medical and Surgical Journal for 1875, page 422, the case of a tumor of the neck, during the removal of which "the subclavian vein and a large vessel near the internal jugular were both wounded. The distended veins mixed up with the friable glandular growth gave way repeatedly under the forceps and ligature. At this time occurred a new source of difficulty. A transparent, viscid, coagulable, and colorless fluid ran out from the tumor and from the lower corner of the wound in quantities as large as an ounce at a time, some six separate times. Together with the dark venous blood, this fluid constantly obscured and filled the bottom of the neck whenever pressure by the finger or sponges was taken off." The inner two thirds of the clavicle were then removed. "The subclavian artery was

sought and pushed aside and an aneurysm needle passed between it and the vein, first out toward the shoulder, and a ligature tied; and second, close to the sterno-clavicular articulation, where the needle and ligatures surrounded the venous trunks at or upon their junction in the left vena innominata. The artery was not wounded nor tied. All bleeding now ceased, but the transparent fluid still oozed out moderately. The wound was lightly packed with sponges and ferric alum; no hæmorrhage occurred, and the transparent fluid did not soak through the sponges. The patient died from shock and exhaustion thirtysix hours after the operation. "No formal autopsy was made, but an examination of the wound showed the subclavian vein tied externally, and also at the junction of the internal jugular and subclavian. The remains of the tumor extended two inches below the clavicle, but were enucleated without piercing the pleura. This fragment of tumor had incorporated into itself several venous trunks or sinuses caught and entangled in the gradual agglomeration of glands. There was no opening into the pleura, no sac running down into the thorax or axilla, no cyst in any direction. The source of the transparent effusion could not be traced. There would seem to be but little doubt that this fluid was lymph from a large branch of the lymphatics in the tumor, or more probably from the thoracic duct where it arches over to join the left subclavian vein. In contact with, if not surrounded by, the glandular enlargement, its thin and transparent walls were readily wounded in trying to remove the lower part of the tumor. No other source for the clear fluid could be found, there being neither cyst, hydrocele of the neck, nor pleural effusion to account for it. The fluid under the microscope exhibited no cells save a few stray blood corpuscles. The patient having fasted for twelve hours before the operation, there would be little, if any, of the milky emulsion of chyle in the duct.

"The fluid poured out of this wound coagulated after contact with the air in a firm jelly, just as blood coagulates. This, no doubt, was due to its fibrin. Its large quantity pointed to a considerable duct as its source, although it must be borne in mind that the whole lymphatic system of the neck was probably vastly enlarged, and secreted great quantities of lymph. Very probably the waste of nutritive plasma by this leakage of lymph in the wound hastened the exhaustion of the patient, and, if due to a wound in the thoracic duct, would have precluded his recovery."

Case II (Boegehold's case, Arch. f. klin. Chir., 1893, vol. xxix, p. 443) .-- In March, 1880, Wilms extirpated a tumor as large as a fist from the left side of the neck of a stout man fortyfive years of age. In the course of the operation Wilms gradually neared the junction of the subclavian and jugular veins. As he was carefully scraping the tissue with a sharp spoon, suddenly there poured out over the operation field a stream of whitish fluid the diameter of a straw, which mingled with the rather freely flowing blood. This fluid could not well be anything else than chyle, for a wounded lymph vessel would have given exit to a clear, or at the most a slightly yellowish, but not whitish, fluid. There was no abscess nor any purulent pleurisy. After this wound of the thoracic duct, the extirpation of the tumor was terminated at once. The milky fluid no longer escaped, and on account of the considerable hæmorrhage the idea of securing it in the depth of the wound was abandoned. The wound was then packed with salicylic wool and an antiseptic bandage applied. The packing was removed the next day without any further appearance of the chyle. The patient recovered without incident, and six months afterward died, presumably from pulmonary metastasis of the carcinoma.

Case III (Case of Dr. A. M. Phelps, of New York; personal communication).—June 4, 1893, at the Mary Fletcher Hospital,

Burlington, Vt., Dr. Phelps operated on a malignant tumor of the left side of the neck. "It was found that the jugular vein passed through the tumor, and this necessitated the removal of three inches of the jugular, near its junction with the subclavian. The tumor extended downward underneath the subclavian vein and involved the deep muscles of the neck. The wound was dressed four days later. There had been a constant profuse discharge, which at first was supposed to be serum, but its color, like that of skimmed milk, and its source from a single point in the wound, as well as its quantity, soon forbade that presumption. I estimate that about three pints a day had been lost. It was sufficient to saturate daily ten or fifteen ordinary bed-sheets folded in a number of thicknesses, in addition to saturating the surgical dressings. The man was rapidly losing flesh. A consultation of staff was held on June 11th, and the consensus of opinion was that the thoracic duet had been severed. The point of a probe the size of a large knitting-needle inserted at the point of evacuation entirely stopped the discharge. The point from which the liquid issued was caught by forceps, which were allowed to remain in place three days. The patient gained a pound a day after the discharge was stopped, and made an excellent recovery."

The duct cut, in his opinion, was one of the divisions or ramifications of the thoracic duct, but the staff thought that the main trunk had been severed.

The fourth case is my own.

Case IV .- Miss S., aged twenty years, was first brought to me in November, 1892, by Dr. Melcher, of Mount Holly, N. J. There was a small enlarged gland on the left side of her neck above the clavicle, a scar at a corresponding point on the right side, and another scar at the upper border of the right breast. From these two places showing scars Dr. Melcher had removed glands which were undoubtedly tubercular. Just below the right clavicle and a little external to its center was a tumor, evidently deep in the apex of the right axilla, firmly attached so as to be practically immovable, and extending, so far as could be ascertained, half way or more from the clavicle to the axillary border. It first appeared about a year ago. I judged it to be a series of enlarged glands, probably attached to the vessels. She had occasionally tingling and numbness in the right arm, and slight ædematous swelling. Soon after she was here Dr. Melcher made an attempt to remove the tumor, but the hæmorrhage was so great as to deter him, and he closed the wound, from which she made a good recovery.

Operation, Jefferson Hospital, January 28, 1893. I made an incision almost vertically in the axis of the body, from the clavicle about four inches downward. I came upon the tumor as soon as I was through the great pectoral muscle. Finding its extent, especially toward the axilla, greater than it appeared from the outside, I made two transverse incisions, converting the whole incision into a cross. I first dissected from the clavicle downward. I found the tumor adherent, not to the clavicle, but to the second rib and the costo-coracoid membrane. With a good deal of care and difficulty I was able to separate the upper border of the tumor from the clavicle and work my way downward and also outward toward the vessels. In a few moments I saw a part of the tissue collapse with inspiration, and I recognized that this was the subclavian vein.

I was finally able to remove the entire tumor, but only after one of the most difficult and tedious dissections I ever made. The tumor was a mass of enlarged glands extending three quarters of the way around the axillary vessels, the upper border alone being free. It was with the greatest difficulty that I could separate the tumor from the vein to which it was especially adherent, but I finally succeeded. The dissection took over an hour and the whole operation was nearly an hour

and a half long. I buttonholed the axillary skin at its posterior border and carried out a drainage tube, otherwise closing the wound and dressing it as usual. The hæmorrhage was moderate, not over eight or ten vessels requiring ligation.

February 11, 1893.—Her recovery was rapid and gratifying. The highest temperature was 99.8°. The drainage tube was removed in forty-eight hours, and the sutures on the third, fifth, and seventh days. On the eighth day she went home perfectly well.

Dr. Kyle reported as follows on the specimen: "Frozen sections from this specimen showed it to be tubercular. The sections were so arranged as to include portions of dense tissue, also the caseous mass. Macroscopically and on cutting through the specimen it resembled lympho-sarcoma, which appearance could be produced by the enlargement of the gland, which would cause pressure on intervening tissue, giving it that peculiar fibrous appearance. By the methyl violet and blue stain the tubercular condition was easily recognized."

She returned to me December 12, 1893, with enlarged glands in the neck on both sides, just above the clavicles and in both axillæ, especially the right one. These glands were high up in the axilla on both sides and were apparently (especially on the right side) very adherent. In the neck the glands were rather peculiar in that while they were very perceptible as tolerably large, nodular masses, evidently composed of a number of glands, the inner portion on both sides was soft, markedly lobular, and apparently contained some fluid. Those on the left side of the neck were larger and gave her a good deal of annoyance and pain, somewhat resembling in this respect those in the right axilla. I advised her therefore to have them removed.

Operation, Jefferson College Hospital, December 15, 1893. Present, Professor Clayton Parkhill, of Denver, and Dr. Hearn and Dr. William J. Taylor. Dr. J. Chalmers Da Costa and Dr. Weaver assisted me. When the patient was etherized and recumbent, I saw a marked change in the condition of all the tumors. The one in the left axilla just below the clavicle could not be found. That on the right side was apparently very much diminished, as were both of those in the neck, the right one being partially perceptible and the left moderately so. The soft, fluid part of the cervical swellings had entirely disappeared.

The right axilla was opened by an incision passing along the border of the tendon of the great pectoral muscle. The operation was tedious and very difficult mechanically, by reason of the extensive and very dense adhesions from the periadentitis and from the former operations. The adhesion to the axillary vein was particularly solid and sometimes was almost as tough as if it had been made of leather. However, after very slow, careful, and patient dissection I was able to get out a large mass of glands.

Having finished the dissection of the glands in the right axilla, I next made an incision above the left clavicle to remove the glands there. There was a great deal of periadenitis, creating very firm adhesions, especially downward and inward toward the junction of the left internal jugular and subclavian veins, both of which were laid bare nearly, but not to their junction. I was carefully dissecting these adhesions away with Allis's blunt dissector, when suddenly I made a small opening in what was apparently an adhesion, and instantly there welled out from it a perfectly limpid fluid. At first I thought I had opened a cyst; but, on observing that the fluid escaped continuously and with a very evident respiratory rhythm, and that the fluid apparently flowed from a tear a fourth of an inch in length, from a tabe about an eighth of an inch in diameter, it occurred to me that it was either one of the dilated left lymphatic ducts just before their

entrance into the thoracic duct, or that, more likely, it was the thoracic duct itself. About two onness of fluid escaped in all. I sucked up a little of it with a hypodermic syringe. It coagulated in a few minutes. Dr. Da Costa suggested that the distinction between the two fluids-i. e., from the lymphatic and the thoracic ducts-could be made by the fact that the fluid in the thoracic duct should be milky, but as she had taken no food since the previous evening (eighteen hours) this gave no help. Against its being the thoracic duct was the fact that it was just behind the upper border of the clavicle, and therefore lay too high for the thoracic duct; but as the glands were being dragged upward, this objection I felt was not valid. Also, although I could introduce a grooved director into the tube from which the fluid was escaping, the director only entered about a half to three quarters of an inch when it met some obstacle. In such a locality and in such a novel experience, I did not care to enlarge the boundaries of science at the possible expense of my patient, and hence I decided to desist from further exploration and remedy the apparent mischief at once. Accordingly I closed the opening by the pressure of one finger, and carefully removed the glands, which were almost entirely loosened at the moment of the accident. Then I seized the two edges of the opening with forceps, and by means of the finest Hagedorn semicircular needle and fine silk I closed the wound. Some little leakage still took place. There was also a little of a similar fluid from the upper part of the wound, but it seemed a general oozing rather than from any distinct vessel. The remainder of the operation was completed with ease, although it was extraordinary what a large mass of glands I removed, in view of the almost utter inability to perceive them when she was etherized and recumbent. Nothing was found to account for the soft and apparently fluid part of the tumor noticed when she was first examined. This soft mass was at least an inch and a half external to the site of the opening into the thoracic duct and nearly as much above it.

A drainage tube was inserted into the wound, but was removed after five hours, having served its function of conducting off most of the bloody wound-fluids, and I feared that its retention would be followed by a lymphatic fistula. Any escape of lymphatic fluid from the thoracic duct I thought should be repressed as quickly as possible by absolute closure of the wound. During the five hours the amount of wound-fluids was very large for so small a wound, amounting to nearly a pint, and its light color showed that the small amount of blood was diluted with a great deal of clear fluid. The dressing the next day was partially saturated by probably an ounce or two, and after that

On the eighth day after the operation, having made an absolutely uneventful recovery, she went home. Not the slightest evidence of trouble appeared in the wound in the neck-neither swelling, redness, nor pain. Her weight on December 11th, four days before the operation, was a hundred and six pounds, and eight days after it, in about the same clothing, a hundred and three pounds. Her highest temperature was 99.8° on the evening of the operation. The following table shows her weight since the operation:

																	Weight.		
December	28,	1893						۰		٠	٠		,					100 pound	ls.
January	6,	1894																101 "	
	12,	6.6			,													100.5	
**	19,	**							,									100:75 **	
**	26,	6.6						ı	ı					ı				100:75 **	

March 15, 1894, same weight; her cough troubles her considerably.

Dr. Kyle reported that in the fluid there were many lympho-

slightly granular, and there were many fat or oil globules, small in size, but large in number. The macroscopic appearance of the fluid was slightly opaque.

Remarks.—First. The anatomy of the thoracic duct. As has been shown here to-night in the beautiful dissections of Mr. Ward Brinton, the thoracic duct does not always empty by a single mouth at the junction of the left jugular and subclavian, but is apt sometimes to break up into two or three ducts or even into a delta, some of the branches emptying into each of these large veins, and, as Dr. Phelps finds from his dissections of the duct, into other deep veins of the neck. Verneuil (Le Sustème veineux, 1853) states that Boullard in twenty-four cases found it to empty by one mouth eighteen times, by two mouths three times, by three mouths twice, and finally once by six mouths, of which two opened into the subclavian, two into the jugular, and one each into the external jugular and the vertebral veins. Lacauchie (Henle, loc. cit.) gives an instance of four terminal canals. In twenty-one injections of the duct Boegehold found that in two cases it divided at its anastomosis with the veins into three or four branches, and in one case, about two inches before its termination, a branch as large as a straw passed to the subclavian, the main trunk emptying at the angle between the subclavian and the jugular. It is therefore possible in all these cases of wound that not the main trunk, but one of these branches-perhaps, as in Boegehold's case, a branch as large as a straw—was injured. Bayford (Boegehold, page 447) records one case of dislocation of the thoracic duct from a curvature of the spine, which might increase materially the possibility of its being wounded should an operation have to be done in such a case. Boegehold (page 455) also quotes a case from Scherb of the partial obstruction of the duct by a calculus. The occasional great height of the final curve of the duct in the neck has already been mentioned.

Secondly. The character of the fluid. There could be no possibility that the source of the fluid was other than the thoracic duct in Boegehold's and Phelps's cases, as, from its milky color, the fluid was evidently chyle. In the other two cases the fluid has been so clear that it resembled serum. I do not know the relation of the hour of operation to the hour of the last meal in Cheever's case. In my own case the patient, having had two prior operations, and suffering from ether nausea, had refused to eat any breakfast whatever, and when I operated, at twelve o'clock noon, it was eighteen hours since she had eaten the previous meal. The quantity of the fluid in Phelps's case was very extraordinary, and leaves no doubt that it could only have been from the thoracic duct. In Cheever's case and my own the quantity and character of the fluid make it reasonably certain that it was from the duct, but it is not so demonstrably sure as in the other two cases.

Third. Treatment. Cheever's case was so speedily fatal from other reasons that no inferences can be drawn from it. In Boegehold's case packing was sufficient to arrest the flow and the patient recovered. In Phelps's case pressure forceps arrested it entirely. In my own case the suture of the vessel was perfectly feasible, and the result was most satisfactory. It seems to me clear that if this procedure can be adopted it should always be done. I very anxiously watched the weight of my patient from week to week for the first few weeks after the operation. Then, finding that she was not losing ground, it was clear to me that she had permanently recovered from the accident, which at first caused me much anxiety.

Fourth. Experimental researches. Boegehold, so far as I know, is the only one who has tested the question by experiment. In his first two experiments, in dogs, he exposed the thoracic duct at its entrance into the veins and wounded it with cytes or lymph-corpuscles of different sizes; some few were scissors. Pneumothorax followed, but disappeared within five days. Eight days after the accident the dogs were killed. trace of pleurisy was found, and the duct at the level of the fourth dorsal vertebra was surrounded with a thin, whitish-red clot of fibrin. The duct was divided for over one fourth of its circumference. In the next three experiments the duct was cut obliquely. On the following day the dogs were evidently sick, with a rapidly increasing frequency of respiration. On the evening of the third or fourth day they died, and at the autopsy the pleural cavity was found full of chyle. The cause of death was compression of the heart and lung from effusion of chyle. In the sixth and seventh experiments he placed a cannula in the duct. This was followed by suppurative pleurisy, with death respectively on the fourteenth and tenth days. At the autopsy the pleura was found covered with fibrinous clots, but as the fever had subsided on the fifth day, he ascribed death to the loss of chyle. In the eighth experiment he ligated the ends of the duct in the neck. On the fourth day he inserted his finger into the pleural cavity. The duct was easily found, as it was distended with chyle. He wounded it slightly with scissors, and seventy-two hours later the dog was killed. The duct and the receptaculum were distended with chyle, and at the site of the wound a small red fibrinous clot was found. Very little chyle had escaped on account of the smallness of the wound.

As a result of his experience he thinks that the complete integrity of the duct for the support of life is not absolutely necessary. He gives a number of instances of complete obliteration or compression of the duct without any symptoms. The collateral circulation of the lymph seemed to be established, and Schmidt and Mulheim have shown experimentally that the closure of the duct in dogs, in whom the canal is always single, did not affect either the digestion or the absorption of albuminous matter. An injury followed by closure of the duct, therefore, is not necessarily fatal. The danger is that if the duct is not closed, either compression of the lungs and heart from the constantly augmenting accumulation of chyle in the pleural cavity will prove fatal, or that the loss of nourishment will be lethal if it escapes externally. Wounds of the duct seem to be entirely capable of healing. Should the heart and lungs be compressed, clearly the pleural cavity should be opened in order to avoid the immediate danger of death from compression, as is shown by Kirchner's case (Arch. f. klin. Chir., 1885, p. 156). This seems to have been an undoubted and severe rupture of the thoracic duct within the thorax, and yet was followed by recovery. It shows that even rupture of the duct may not necessarily be fatal.

A little girl, nine years of age, healthy although not very strong, was pushed violently against a window-sill, injuring her at the level of the third rib. Marked orthopnœa, with cyanosis and sweating, and dilatation of the nostrils followed in the course of two weeks. The right half of the thorax was broader than the left up to the level of the spine of the scapula and the third rib. The heart was pushed to the left, and the liver extended two fingers' breadth below the border of the ribs. The temperature was normal. The right chest was punctured in the fifth intercostal space and a litre of fluid resembling milk was poured out. Examination by the microscope showed undoubtedly that it was chyle. Ten days later the dyspnœa was so great that puncture was again contemplated, but under warm baths and slight purgation by senna the improvement was such that puncture was not done a second time, and complete recovery followed. In six months the child was better than prior to the attack.

Kirchner states that, even including some uncertain cases, there are but seventeen on record of injury of the thoracic duct, either in the neck, chest, or abdomen; six resulting in

chylous ascites; nine in chylo-thorax; one of hydrops lacteus from the collection of lymph in the mediastinum; and finally, the case of Boegehold, the only instance he gives of injury in the neck. The three additional cases I have reported here bring the total number up to twenty, and of wounds in the neck alone to four.

Busey (Trans. of the Assoc. of Amer. Phys., 1889, vol. iv, p. 76) refers to a number of cases of injury to peripheral lymphatics by bleeding, etc., and also the effusion of chyle into the thorax, abdomen, tunica vaginalis testis, etc. In the discussion Welch said: "I do not think that the mere occlusion of the thoracic duct, still less obstruction to the venous flow in the subclavian veins, is followed by serious interference with the flow of lymph and chyle. I have found the thoracic duct completely occluded by a tuberculous thrombus in a case of acute miliary tuberculosis without any such effect."

The pressure in the thoracic duct is not very high. According to Weiss, in the neck it reaches from nine to fifteen millimetres of mercury.

Dr. John II. Brinton said that, in such a case as Dr. Keen had reported, it was possible that the vessel wounded was one of several branches.

Dr. Joseph Hearn asked what would have been the objection to ligature in this case.

Dr. Keen said that the statistics which he had quoted showed that the termination in multiple ducts was quite rare, the usual termination being by a single duct. In this case the vessel cut had certainly been as large as a straw. He would object to the use of a ligature unless he was sure that there were other ductsIf he was sure of this he should not hesitate.

Dr. James M. Barton said that, in cases of longitudinal wounds in veins, he had closed them laterally by grasping the edges of the wound with two or three forceps and ligating. This made a bulky mass that encroached too much upon the caliber of the injured vessel. It had occurred to him that it would be better to close the wound in the vessel with a broad pressure forceps and allow it to remain. This would be even better than suture, for, no matter how fine the needle, the needleholes might leak, and, in addition, sutures would encroach more upon the caliber of the vessel than a properly applied pressure forceps would.

Dr. William J. Taylor said that, some years before, he had reported a case of hemorrhage from the superior longitudinal sinus, which he had been able to control by clamping the wound in the sinus with a hemostatic forceps. This he had allowed to remain for three days. The patient had made a complete recovery.

Dr. T. S. K. Morton said that some time before Dr. Edward Martin had made an interesting suggestion as to the treatment of lateral wounds of veins, etc., which was to use fine catgut soaked in alcohol, as the swelling of the catgut would close the small holes made by the needle.

## New Inbentions, etc.

A NEW LACRYMAL AND MIDDLE-EAR SYRINGE.

By Frank C. Todd, M. D., MINNEAPOLIS, MINN.

The value of antiseptic irrigation is unquestioned in the treatment of a lacrymal absecss, as is also that of the copious use of a warm boric-acid solution or ordinary astringents following the operation for stenosis for epiphora.

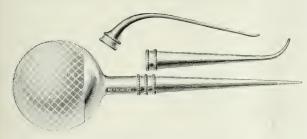

The piston lacrymal syringe, commonly used, is unsatisfactory, as it is continually getting out of order. It injects either air or bubbles into the lacrymal canal instead of the solution, or the piston stops half way, or goes by jerks, thus annoying the operator and causing unnecessary pain to the patient. Therefore one never feels confidence in the use of it.

Dr. Colburn's syringe is found useful as a means of applying cocaine or like remedies, but is useless for the purpose of antiseptic irrigation, and is as uncontrollable as the piston syringe.

This new lacrymal and middle-ear syringe, made by E. B. Meyrowitz from my design, is intended to obviate the objections to these instruments and retain the advantages of both. There are two lacrymal points and one middle-ear point, as shown in the cut. These points are small enough to introduce into the lacrymal or auditory canals and yet sufficiently large to prevent their breaking.

The lacrymal points may be introduced in the same way as those of any lacrymal syringe, the choice of the two depending upon the surgeon's habit of operating behind or in front of his patient.

After the introduction, the first and second fingers are placed

upon the shield, and the thumb is placed upon the bulb itself. By closing the first two fingers firmly around the instrument the operator obtains perfect control of the syringe. He then forces the current into the canal by pressure of the thumb, using as much or as little force as is desired.

The bulb is of such a size that a copious stream may be used, and one introduction, as a rule, will suffice for a thorough cleansing of the parts.

The points and the shield are detachable, and thus the instrument may be kept aseptic, and even the bulb may be washed in any of the ordinary antiseptic solutions.

The instrument is so constructed that the point may be taken off in order to fill the bulb, the hole in the point being so small that otherwise the bulb fills slowly. It will be observed that the point for the introduction of fluids into the middle enr is bent at an angle that enables the operator to retain his view.

## Miscellany.

The American Laryngological Association will hold its sixteenth annual congress at the Arlington Hotel, Washington, on May 30th and 31st and June 1st, under the presidency of Dr. D. Bryson Delavan, of New York. In addition to the president's address, the following papers will be read: Nasal Polypus; its Association with Ethmoditis and its Treatment by Resection of the Middle Turbinated Body, by Dr.

W. E. Casselberry, of Chicago; Papillary Hypertrophy of the Nasal Mucous Membrane compared with a Papillary Fibroma or Papilloma, by Dr. Jonathan Wright, of Brooklyn; The Use of Metallic Electrodes in the Treatment of Nasal and Post-nasal Disease, by Dr. Clarence C. Rice, of New York; Observations on some of the Results of Cutting Operations on the Nasal Sæptum, by Dr. Thomas R. French, of Brooklyn; Some Comments on the Surgery of the Antrum of Highmore, by Dr. W. H. Daly, of Pittsburgh, Pa.; A Case of Odontoma invading the Antrum of Highmore and corresponding Nasal Fossa, with the Application of an Improved Method of Anæsthesia adapted to Operations in the Mouth, and A Case of Foreign Body (Gold Coin) engaged in the Ventricles of the Larynx, by Dr. A. W. de Roaldes, of New Orleans; Foreign Bodies in the Larynx, with Report of a Case, by Dr. Charles M. Shields, of Richmond; Three Cases of Papilloma of the Larynx, by Dr. Charles H. Knight, of New York; Report of a Case of Sarcoma and of One of Epithelioma of the Larynx, by Dr. Arthur Ames Bliss, of Philadelphia; A Case of Laryngectomy by a Novel Method, by Dr. H. L. Smith, of New Haven; Two Cases of Tumor of the Epiglottis, by Dr. J. Solis-Cohen, of Philadel-

phia; Singers' Nodes, by Dr. F. I. Knight, of Boston; A Case of Cyst of the Larnyx—Pharyngomycosis, by Dr. E. F. Ingals, of Chicago; Exudative Pharyngitis, by Dr. W. C. Glasgow, of St. Louis; A Case of Sarcoma of the Tonsil, by Dr. A. W. Watson, of Philadelphia; The Importance of an Early Diagnosis of Malignant Tumors of the Throat, by Dr. J. W. Gleitsmann, of New York; On Neurasthenic Throat, with Illustrative Cases, by Dr. W. P. Porcher, of Charleston; and A Contribution to the Study of the Ætiology of Rheumatic Affections of the Body due to Tonsillar Diseases, by Dr. H. L. Wagner, of San Francisco.

In addition, there will be a discussion on the Surgery of the Accessory Sinuses of the Nose, by Dr. F. H. Bosworth, of New York, Dr. J. H. Bryan, of Washington, Dr. J. N. Mackenzie, of Baltimore, and Dr. J. O. Roc, of Rochester.

The New York Academy of Medicine.—The programme for the meeting of Thursday evening, the 3d inst., included a paper on The Adoption by the Academy of a Nomenclature for the Different Classes of Infectious Diseases, by Dr. W. II. Thomson, with a discussion by Dr. T. M. Prudden, Dr. II. M. Biggs, Dr. John Brannan, Dr. J. West Roosevelt, and others.

At the next meeting of the Section in Genito-urinary Surgery, on Tuesday evening, the 8th inst., Dr. R. W. Taylor will present pathological specimens and cases illustrative of the mixed malignant growth of the testicle; Dr. C. L. Gibson will present specimens and cases showing the result of castration for tubercular epididymitis, also read a paper on Castration for Tubercular Testis; and Dr. H. Goldenberg will read a paper entitled Posterior Urethritis, and the Diagnostic Value of the Modified Thompson Test.

At the next meeting of the Section in Pædiatrics, on Thursday evening, the 10th inst., cases will be presented and the subject of The Management of the Breast-fed Infant will be discussed as follows: Management of the Breast and Nipples before and during the Puerperal Period, by Dr. J. Clifton Edgar; Diet of the Nursing Mother, by Dr. Jerome Walker; Wet-nursing: Mixed Feeding—Indications for Weaning; Examination of Breast-milk, by Dr. L. Emmett Holt; and Feeding after Weaning, by Dr. William L. Stowell. A general discussion will follow.

At the next meeting of the Section in General Surgery, on Monday evening, the 14th inst., patients will be presented by Dr. R. F. Weir, Dr. W. T. Bull, Dr. V. P. Gibney, Dr. Robert Abbe, Dr. A. J. McCosh, and Dr. B. B. Gallaudet. Papers will be read as follows: The Influence of Physiological Rest on Prolapse of the Rectum, by Dr. J. D. Bryant; and Malignant Œdema, by Dr. George R. White. There will be an exhibition of pathological specimens and new apparatus.

Physical Fitness for Service in the French Army.—The Province médicale for March 31st contains an abstract of an article published in the Bulletin officiel, setting forth instructions which will, in the future, serve as a basis for the plan of operation in the examinations and in the recruiting bureau. This document carefully reviews all the preparations relative to the auxiliary service, to exclusion from it, to the enlisting, and to the pay and the pension. It indicates the method of examining men who are rendered incapable, by reason of sickness or infirmities, of serving, also the means of detecting those simulating sickness. The most interesting part of this document is the list of infirmities and deformities compatible with the auxiliary service. Men attacked with any one of these infirmities will not be called upon except in case of war or mobilization. Aside from these cases, young men who are simply sickly or of feeble constitution will be employed in the accessory service or in the section of administration. The following list is an enumeration of the infirmities under which are classed the men who are in the auxiliary service:

- 1. Feeble constitution.
- 2. Obesity.
- 3. Pityriasis and ichthyosis, if the first is not extensive and the second is not generalized.
- 4. Benign tumors, cysts, fatty tumors, etc., cicatrices situated in regions where they do not affect the ability to carry the regular equipments.
- Nævi materni and erectile tumors which are but slightly developed or are not exposed to constant pressure.
- 6. Extensive alopecia independent of favus and of ringworm of the scalp; benign tumors of the cranium, such as wens and exostoses; horny outgrowths and cicatrices which do not cause any inconvenience other than that of annoyance in wearing the military cap.
- 7. Entire loss of the external ear, its partial adhesion to the skull, and malformations which are not very extensive.
- 8. Perforation of the membrana tympani without otorrhœal complications.
  - 9. Extreme deformity.
  - 10. Facial mutilations.
- Symblepharon, which, unless causing much trouble in the movements of the eyelids, is no obstacle to the visual function.
  - 12. Ciliary blepharitis without inversion of the eyelids.
- 13. Opacity of the cornea, exudations involving the pupil, according to the intensity of diminution of the visual acuity.
- 14. Myopia exceeding six dioptres, if the visual acuity can be brought to the proper limit by means of concave glasses, and if there are no extensive chorioid lesions.
  - 15. Hypermetropia and astigmatism.
  - 16. Functional strabismus.
- 17. The loss of a large number of teeth, if the gums are not altered, and if the condition of the subject is satisfactory.
  - 18. Congenital or accidental harelip, if not very extensive.
- 19. Stuttering, if not sufficiently pronounced to prevent the intelligible transmission of orders.
- 20. Tumors of the neck, such as goitre, serous cysts, and adenitis, slightly developed.
- 21. Deformities of the chest, such as sinking or protuberance of the sternum or of the ribs which does not detract from the

functions of the internal organs; non-development, abnormal curvatures, pseudarthrosis of the clavicle, and deformities of the shoulder-blade which do not impede the movements of the upper limbs.

- 22. Inguinal and crural hernia which does not extend beyond the external orifice of the canal.
- 23. Cryptorchidism, when the subject presents the general characteristics of virility.
- 24. Congenital or acquired deformities which do not noticeably impede the functions, such as a voluminous and, at the same time, slightly deformed callosity, a moderate incurvation of the upper or lower limbs, inequality of the upper limbs, and contracture of the lower limbs if it results only in a slight lameness,
- 25. Varicose veins if they exist in the condition stipulated for non-acceptance in the active service.
- 26. Chronic hygroma and synovial cysts, if sufficiently pronounced for exclusion from active service, but not impeding the action of the joints.
- 27. Stiffness of a joint, with slight diminution of freedom in the movements, which does not perceptibly impede the action of the limbs, such as incomplete extension of the forearm on the arm and incomplete flexion of the leg on the thigh, the reverse movements being entirely free; permanent and complete flexion of the little finger of either hand, and incomplete flexion of several fingers.
- 28. Incurvation, loss, or mutilation of the fingers or of the toes, not compatible with active service, which do not noticeably embarrass the functions of the hand or foot.
- 29. Supernumerary fingers and toes, overriding of the toes, hammer toes, subungual exostosis presenting itself under the conditions named for non-acceptance for active service.
  - 30, Defective stature.

A Circular of Information to Physicians regarding the Measures adopted by the Board of Health for the Prevention of Tuberculosis in the City of New York.—The following circular, dated February 13, 1894, has been issued by the board:

The communicability of pulmonary tuberculosis has been so thoroughly established, and is now so generally recognized by the medical profession throughout the world, that the Board of Health of New York City has determined that the time has arrived when active steps should be taken looking toward its prevention in this city. The board has therefore resolved to adopt the following preliminary measures:

- 1. The department will hereafter register the name, address, sex, and age of every person suffering from tuberculosis in this city, so far as such information can be obtained, and respectfully requests that hereafter all physicians forward such information on the postal cards ordinarily employed for reporting cases of contagious disease. This information will be solely for the use of the department, and in no case will visits be made to such persons by the inspectors of the department, nor will the department assume any sanitary surveillance of such patients, unless the person resides in a tenement house, boarding house, or hotel, or unless the attending physician requests that an inspection of the premises be made; and in no case where the person resides in a tenement house, boarding house, or hotel will any action be taken if the physician requests that no visits be made by inspectors and is willing himself to deliver circulars of information or furnish such equivalent information as is required to prevent the communication of the disease to others.
- Where the department obtains knowledge of the existence of patients with pulmonary consumption residing in tenement houses, boarding houses, or hotels (unless the case has been reported by a physician and he requests that no visits be

made), inspectors will visit the premises and family, will leave circulars of information, will instruct the person suffering from consumption and the family as to the measures which should be taken to guard against the spread of the disease, and, if it is considered necessary, will make such recommendations for the cleansing or renovation of the apartment as may be required to render it free from infectious matter.

- 3. In all cases where it comes to the knowledge of the department that premises which have been occupied by a consumptive have been vacated by death or removal, an inspector will visit the premises and direct the removal of infected articles, such as carpets, 'rugs, bedding, etc., for disinfection, and will make such written recommendations to the board as to the cleansing and renovation of the apartment as may be required. An order embodying these recommendations will then be issued to the owner of the premises, and compliance with this order will be enforced. No other persons than those there residing at the time will be allowed to occupy such apartments until the order of the board has been complied with. Infected articles, such as carpets, rugs, etc., will be removed by the department, disinfected, and returned, without charge to the owner.
- 4. For the prevention and treatment of pulmonary tuberculosis it becomes of vital importance that a positive diagnosis shall be made at the earliest possible moment, and, that the value of bacteriological examinations of the sputa for this purpose may be at the service of physicians in all cases not under treatment in hospitals, the department is prepared to make such bacteriological examinations for diagnosis, if samples of the sputa, freshly discharged, are furnished in clean, wide-necked, stoppered bottles, accompanied by the name, age, sex, and address of the patient, the duration of the disease, and the name and address of the attending physician. Bottles for collecting such sputa, with blank forms to be filled in, can be obtained at any of the drug stores now used as stations for the distribution and collection of serum tubes for diphtheria cultures. After the sputum has been obtained, if the bottle, with the accompanying slip filled out, is left at any one of these stations, it will be collected by the department and examined microscopically, and a report of the examination forwarded to the attending physician free of charge.
- 5. The authorities of all public institutions, such as hospitals, dispensaries, asylums, prisons, homes, etc., will be required to furnish to the department the name, sex, age, occupation, and last address of every consumptive coming under observation within seven days of such time.

It is the earnest wish of the board of health that all practicing physicians in this city co-operate with the board in an earnest and determined effort to restrict the ravages of the most prevalent and formidable disease with which we have to deal.

The late Dr. Brown-Sequard.—The Lancet for April 14th contains a short account of this eminent physician, of which the following is the substance: Dr. Brown-Séquard was of French and Irish parentage, and was born in the Island of Mauritius in 1817. His earlier history is somewhat obscure, but it seems that he left Mauritius when still a child and went to the United States, where he received his early education. In 1838 he went to Paris, where he devoted himself almost entirely to experimental physiology, and in 1849 he described the sensory decussation in the spinal cord with which his name has since become so closely associated. He occupied himself chiefly in the study of nervous physiology and pathology, and established so great a reputation in that field that he was asked to deliver a course of lectures before the Royal College of Surgeons of England. These lectures aroused the keenest interest, not only because

they gave a clear and concise account of the current knowledge of nervous physiology and pathology, but because they contained much that was new and the result of the author's experiments. The originality of his views, the care taken in the acquirement of this knowledge, and the charming personality of the man excited an interest in nervous physiology and pathology, and so successful were the lectures that, shortly after, he was asked to deliver them in Edinburgh, in Glasgow, and in Dublin, In 1859 he established himself in London, and was appointed physician to the National Hospital for the Paralyzed and Epileptic. He also joined the Royal College of Physicians of London. He stayed, however, only a short time in England, and went to America to accept a chair at Harvard University, where he remained five years. At the end of that time he returned to Paris, where he became professor at the École de médecine. In 1873 he returned to America and began to practice in New York, and edited, in connection with Dr. Seguin, the Archives of Scientific and Practical Medicine. In 1876 he was again in London delivering a course of lectures in which he combated the current doctrines of nervous physiology and also other theories which have since been generally accepted. Two years later he once more returned to Paris and succeeded Claude Bernard as professor at the Collége de France, where he remained until his

He was an honest, single-minded man, devoting all his energies during the last years of his life to the investigation of his testicular fluid. In everything that he did a patient search for knowledge and truth was one of his highest characteristics. The sacrifices he made can never be fully appreciated except by those who knew him best. The following extract from a letter to one of his friends will serve as an illustration of this: "I have a very much harder fight for the doctrines relating to the brain than I had, at the time I first became acquainted with you, for doctrines relating to the spinal cord. If I did not love truth much more than comfort, ease, and quietness, I would give up the painful, heavy task I have given to myself. So long, however, as I have a breath of power of mind and body, I shall continue the efforts begun in London."

Dr. Brown-Séquard was a man of simple habits, going to bed and rising very early, as he found these hours best suited to his work. He cared for nothing outside of physiology, and spent nearly 10,000 francs during the last two years in dispensing his extract gratuitously. The writer gives the following illustrations of how little he cared for money: A wealthy Amercan asked him to go to Italy to see his son, and he refused on the ground that it was not a case where his advice was particularly indicated, and suggested another physician. The American wrote that it was Brown-Séquard he wanted, and offered the enormous sum of \$50,000; but he had made up his mind in this particular case, and the money had no temptation for him. On another occasion he received, when in London, a telegram asking him to go to Liverpool to see a patient, and telling him that the fee would be \$1,000. He replied that he should be in Liverpool in a day or two to sail for New York, when he would see the patient, and the fee would be five guineas. It is hardly to be wondered at, says the writer, that he died far from wealthy.

A Bit of Artistic Anatomy.—In the March number of the Revue illustrie de polytechnique médicule et chirusqueule Dr. Bougon makes the following statements: Let a man stand with his arms stretched horizontally one to each side, and to ascertain his height we have only to measure the distance from the tip of one hand to that of the other. If there is any error, the horizontal measurement is rather above than below the stature. Another way of ascertaining a man's stature is that of multiply-

ing the length of his foot by six and five tenths. If we multiply by seven we get the maximum limit, if by six, then a minimum limit; the real stature falls somewhere between the two. This method of measurement gives more correct results with men than with women. From the tip of the chin to the beginning of the hair of the head is three times the length of the nose. The forehead does not generally measure the same as the nose, because the latter organ is not always situated in the middle of the height of the face. In spite of many individual differences, it may be said that, as a general thing, the forehead measures a little less than the nose, and that the nose is itself a little shorter than that portion of the face which is beneath it. In persons who have lost their teeth the distance from the nose to the chin may be so reduced that the end of the nose seems on the lookout to meet the chin, the point of which seems to advance like the tip of a Scotch shoe. The lowest foreheads are seen in women. In some women the forehead is not more than a third as high as the length of the nose, even when the hair is dressed in Chinese fashion; but this is exceptional. The ear has the same length as the nose. It is situated on a level with the nose when the head is held quite horizontal. The space between the two eyes is equal to the length of an eye. As a rule, beginners draw the two eyes too near together. It is considered by artists that in a human being of fine type the total length of the body is seven and a half times that of the head; as a matter of fact, it is never more than seven times that length, save in certain young persons who are tall and thin, with the head quite small.

The Ice-bag as a Cardiac Stimulant.—A writer in La Médecine moderne is quoted in La Province médicale for April 7th as saying that the application of an ice-bag over the heart, according to Dr. Jullien, is a powerful therapeutic measure. It seems that in 1887 M. Jullien read in the Gazzetta delle cliniche an essay on this subject by Dr. Silva, and was struck with the author's conclusions. Experimentation upon animals had shown the possibility of raising the blood pressure rapidly from a hundred and twenty millimetres to a hundred and seventy and even a hundred and ninety, and of diminishing the frequency of the pulsations considerably; and these results had been confirmed clinically. M. Jullien was not slow to verify these observations for himself. One day he was called to take charge of a patient attacked with typhoid fever. He advised treatment by means of cold baths, and transferred the patient, a large and strong young girl, to the care of a colleague. Soon afterward, however, his colleague's illness rendered it necessary for him to take charge of the case again. It was a grave one and the febrile phenomena were intense. The elevation of temperature proved rebellious to the use of cold water. Soon there was a typical picture of the ataxo-adynamic form of the disease. The patient had lost consciousness entirely and lay on the bed entirely uncovered in a tetanic attitude varied only by certain spasms of the head. The temperature remained all the time above 104°; the pulse had reached successively 120, 140, and 160. Under these circumstances M. Jullien fancied that the application of ice over the heart might constitute a last resort, and he made bold to carry it out. He admits that it was not without timidity that he placed the rubber bag on the region which scarcely showed the tumultuous and enfeebled beats of the exhausted heart. He watched the pulse closely, ready to stop the attempt at the first signal of danger. But in less than fifteen minutes he saw the number of the pulsations diminish and their amplitude increase; in a short time the almost imperceptible undulations of the artery gave place to more decided elevations. Whenever he removed the refrigerant the alarming symptoms returned immediately, so that after

many trials he concluded to leave the ice-bag in place for several days. After that the temperature yielded, the cerebral phenomena disappeared, and the patient was out of danger. He is convinced that she owed her safety to the decisive measure which he had adopted. In another case also he accomplished a result equally remarkable by this means. In conclusion, he remarks that the beneficial effects show themselves in from fifteen to twenty minutes from the beginning of the application, and reach their maximum at the end of an hour. It is true, he says, that they are very evanescent, disappearing rapidly when the application is suspended, but there is no danger in prolonging it as long as the general condition remains precarious. In some cases, under its action, the height of the pulsation has been observed to be tripled, which means a pulse ampler, fuller, and more tense, with the subsidence of dicrotism, intermittence, and irregularity, and with a longer duration of the diastole. An interesting fact noted is that the effects of alcohol and those of atropine on the circulation are in a measure neutralized by the ice-bag. This, says the author, is not astonishing, since alcohol has the property of lowering the blood pressure by paralyzing the vaso-motor nerves, and atropine increases the frequency of the pulse by paralyzing the pneumogastric nerve. This antagonism, he suggests, may possibly be serviceable in some cases of poisoning.

The Treatment of Infantile Convulsions.—In the Lyon médical for April 8th we find a résumé of an article, by Dr. A. F. Plicque, which appeared in the Gazette médicale de Paris for March 24th. Whatever may be the cause of the convulsions, says the author, which may be investigated subsequently. action must be taken at once. It is well to use inhalations of ether as an antispasmodic, since that drug can almost always be obtained without loss of time. The bowels should be emptied if necessary by means of an enema containing salt (a tablespoonful of salt to a glass of warm water). This enema is to be preferred to those of more complicated constitution, because they require more time for their preparation. To keep up the antispasmodic action of the ether, Dr. J. Simon advises an enema consisting of twenty drops of tincture of musk, five grains of chloral, and two ounces of warm water. This is intended for a child from three to six months old. The dose of chloral should be not more than four grains for a child under that age, and may be increased to fifteen grains for a child a year old. The following is a suitable antispasmodic draught: Potassium bromide, fifteen grains; tincture of musk, twenty drops: syrup of ether, a drachm and a half to two drachms; syrup of orange flowers, an ounce; linden water, four ounces. Until the child has passed water abundantly there is danger of further convulsions, and he should be watched closely.

Tonsillar Nephritis .- In the April number of the Annales des maladies de l'oreille, du larynx, du nez et du pharynx there is a summary of an article by Dr. A. Thouvenet, published in the Limousin médical, in which he relates the case of a woman, forty-five years old, who was suddenly attacked with acute lacunar amygdalitis. In ten days after the beginning of convalescence she had headache, attacks of vertigo, and intense dyspnæa. The bruit de galop was observed, the eyelids and the legs were ædematous, and the urine was highly albuminous. After a month of treatment the albuminuria disappeared, and thenceforward the patient remained well. The author is convinced that many cases of nephritis which are ascribed to cold are in reality consequent on attacks of inflammation of the tonsils which have been overlooked, and that sometimes the nephritis occurs after such an interval that the idea of any relation between the two morbid manifestations is lost sight of.

## Vectures und Addresses.

# LECTURES ON THE DIAGNOSIS OF ABDOMINAL TUMORS.

By WILLIAM OSLER, M.D.,
PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY.

(Concluded from page 550.)

IV. MISCELLANEOUS TUMORS.—In this group I shall place seven cases, in two of which the diagnosis was doubtful or could not be definitely made.

(a) A Cyst of the Abdomen of Unknown Origin (Mesenteric).—The following case presents many remarkable features. For more than two years he has had recurring distention of the abdomen, which reaches such a size that he has to be tapped. With the exception of the period of onset, from October to December, 1891, during which he lost about fifty pounds in weight, he has remained in excellent condition, and is inconvenienced only by the bulk of the fluid as it accumulates. He has usually gone to work the day after the tapping. The physical signs are those of a cyst. The dullness is in the front of the abdomen, with resonance in the flanks. He was tapped eight times in 1892, and five times up to date this year. The quantity removed has varied from one gallon to five gallons and a half. At the last two tappings the amount has been only a gallon and a gallon and a half. At first the fluid was dark and bloody, but since the second aspiration it has been a turbid, muddylooking fluid, alkaline in reaction, containing leucocytes in a condition of disintegration, much granular and molecular débris, and very many cholesterin crystals. I regret that no chemical examination was made of the digestive properties of the sample of the fluid which was sent to me. Dr. Miller has reported recently that the patient is in the best of health, and the amount of fluid is gradually diminishing.

Case L. Cyst of Doubtful Origin.—November 29, 1892. I saw to-day the folio ring very unusual and remarkable case:

X. F., aged forty-four years. Referred to me by Dr. G. B. Miller, of Philadelphia. Patient is a large-framed, stout man, looking the picture of health.

Family history is good. His personal history is also excellent. He had the usual diseases of childhood; scarlet fever, but not a very severe attack. He has had two attacks of gonorrhœa; has never had syphilis. He has been married ten years; no children. He uses alcohol moderately; has never been a heavy drinker. At times during the past six or eight years 'he has had "gouty" pains about the joints. In October, 1891, he noticed that he was getting uncomfortably large in the abdomen, and for this he took three bottles of some "reduction remedy," and lost in weight everywhere except in the abdomen, which became progressively enlarged. He then consulted Dr. Loeling, who told him he had fluid in the abdomen. He kept at work, however, until December, feeling weak and having occasional attacks of nausea and vomiting. The distention of the abdomen became so extreme, in spite of active catharsis and diuretics, that, on December 26th, he was tapped and five gallons and a half of a dark, bloody fluid withdrawn. An examination of the abdomen after removal of the fluid failed to reveal any hardness, tenderness, or tumor. The urine at this

time was negative. He lost in weight from two bundred and fifty pounds to two hundred and two pounds. After the first tapping he gained in strength, and very quickly went to his business. Gradually, however, throughout January the fluid reaccumulated, and on February 14, 1892, he was again tapped, and three gallons of dark, bloody fluid removed. Without any aggravation of his general condition, and without any special interference with his business, the fluid continued to reaccumulate at intervals, and he was tapped on the following dates: March 25th, five gallons and a quarter; May 5th, five gallons and a half of dark serum; June 12th, one gallon; June 22d, dry tapping, no fluid was obtained; July 9th, twenty-eight pounds; August 12th, three gallons and a half of muddy, turbid fluid; October 4th, twenty-six pounds of turbid, muddy fluid; November 22d, last tapping, three gallons removed. He has felt no inconvenience from the tappings, and has usually resumed work on the following day. The only trouble has been the gradual increase in the size of the abdomen, which causes shortness of breath on exertion and a feeling of tension. He has never at any time had swelling of the feet; the bowels have been regular; the appetite has been lately very good, and, as a rule, with the exception of a short period this summer when he got pale and thin, he has been in very good health and has been able to attend to his work systematically.

Present Condition.—As stated, the patient is a large-framed, powerfully built man, looking the picture of health. The color is good; the venules on the cheeks are somewhat marked; the tongue is clean; the pulse is quiet, 78 a minute; tension moderate; no sclerosis of the arteries.

The abdomen is moderately full, but not larger than is frequently seen in a man of his build. It is symmetrical, not specially prominent in any region. The pulsation of the abdominal aorta is not transmitted to the surface; respiratory movements of the abdomen are natural. There is no special enlargement of the superficial veins. The inguinal glands are not enlarged. On palpation it is everywhere soft and painless. No tumor masses or areas of specially increased resistance are to be felt. On deep palpation below the right costal margin, and during inspiration, the edge of the liver can be touched. Fluctuation can not be obtained.

On percussion the entire front of the abdomen is flat, and only on the deepest percussion in the region of the navel is there flat tympany. The dullness continues into the left flank, but there is a flat tympany high up beneath the tenth and eleventh ribs, and this is continuous in the left hypochondriac and left epigastric areas with the stomach tympany. In the right flank, between the costal margin and the ileum, there is resonance. On turning from side to side, resonance on the left side becomes more extensive, that on the right side not much changed. In the nipple line the liver dullness begins at the lower margin of the sixth rib, and there is no tympanitic note below the costal margin. The flat note extends to the pubes. In the erect posture there is tympany in the epiga-tric and left hypochondriac regions, and on the left side beneath the lower ribs.

The material removed at the last tapping was turbid, somewhat creamy looking. On microscopical examination it contains numerous leucocytes in a condition of disintegration, larger cells in a state of advanced fatty degeneration, and very numerous cholesterin crystals.

Of course the first thought in this case that suggested itself was that the condition was an anomalous form of ascites, due either to chronic peritonitis or to liver disease. The patient's history, the absence of any trace of jaundice, the retention of general nutrition, and the absence of any evidences on examination of enlargement or contraction of the liver seems definitely to rule out hepatic disease—cirrhosis, perihepatitis, or tumor. Nor did it seem likely that any of the known forms of disease of the peritonaum itself could cause recurring ascites without serious deterioration in the health, tuberculosis, cancer, or those remarkable forms of epithelial papillomata involving chiefly the omentum to which Lawson Tait refers.

On the other hand, the existence at first of a bloody fluid, the filling of the abdomen repeatedly without serious damage to the health, the readiness with which the patient gets up and goes about immediately after the tapping, the physical examination, the presence of cholesterin in the fluid, suggest strongly the existence of cystic disease, either of the omentum or of the pancreas, most probably of the former.

January 26, 1893.—Patient looks in robust health. Abdomen full, but not so much as at former visit. Everywhere soft, but more resistant on the right side; and on deep pressure to the right of and a little above the navel there is an ill defined mass. No definite fluctuation obtained. Percussion is clear in epigastric and upper umbilical region and to the left side shading off toward the middle of Poppart's ligament. Dull in hypogastric, right iliac, right lumbar, and right half of umbilical, and when he turns on the left side the dullness persists and the bowel tympany on the left side is exaggerated.

Tapped again April 8, 1893, and only fifteen pounds of fluid removed. He was tapped June 17th, three fourths of a gallon removed; October 1st, a gallon and a half; and November 26th, one gallon removed.

Additional Note, February, 1894—He had been doing very well, and had been tapped only once since last date. One Friday, during a business trip, he felt very ill on the train, and had a great deal of abdominal pain and vomiting that night. There was no very special distention of the abdomen, but there was a great deal of sensitiveness on palpation. Attempts were made in various ways to move the bowels without any effect. On Saturday he was very much worse, and seemed collapsed and feeble. There were a few small discharges from the bowels, chiefly of blood. There was not very great abdominal distention. He had vomiting and great depression, which increased, and he died on the Sunday evening.

Through the kindness of Dr. Loeling and Dr. Miller I was notified of the post-mortem and was present. The body was that of a large-framed, well-nourished man. The panniculus over the abdomen was at least two inches and a half in thickness. There was no special distention of the abdomen.

Peritonæum: No exudation, serous or fibrinous. In the right iliac and lumbar regions there was a large cyst, the anterior wall of which was adherent in several places to the abdominal wall, and in addition there were several strong bridles of adhesions, one, the longest, from the left side of the cyst to the peritonæum in the neighborhood of the left crest of the ilium. Two groups of fibrous bands passed from the left cornu of the cyst to the abdominal wall, just to the left of the navel. There were also one or two smaller bands of adhesions, and at one point the upper part of the jejunum was closely adherent to the top of the cyst. After freely exposing the peritonæum by a crucial incision the cyst was seen occupying the position already mentioned. In the lumbar region there were several coils of the small intestine which had passed beneath the bands of adhesion, uniting the left cornu of the cyst with the abdominal

wall near the navel. There were two different loops through which the coils of intestine had passed; one anterior, through which about eight inches of the jejunum had passed and the intestine was only slightly reddened, whereas through the posterior loop about eighteen inches of the upper part of the ileum had passed and had become strangulated. The coils were of a deep maroon color, swollen and infiltrated, and the attached portion of the mesentery was enormously thickened and also plum-colored. The peritonæum over these strangulated coils was smooth, there was no fibrinous exudate, and they could be withdrawn without any difficulty through the snare.

The intestines were then removed as far as a foot above the ileo-cæcal valve. They presented nothing of note except in the strangulated portion just described. After their removal the position of the cyst could be clearly determined. It was of about the size of a man's head, occupied the right iliac and right lumbar regions, and extended to the left beyond the middle line. It lay directly upon the spine and on the lumbar and iliac muscles on the right side. The hand could be placed beneath it, and it could be lifted readily from its bed. The lower foot of the ileum was closely attached to its left and lower margin; below was the cæcum, and the appendix formed a long, flattened, cord-like structure passing up its posterior wall. The ascending colon lay along its right side. The tumor lay in the mesentery of the last foot or eighteen inches of the ileum, and it was removed very readily by stripping the ascending colon and cæcum from its attachment to the peritonæum. The sac had a grayish-white appearance, except at its left side, where it was stained of a greenish color. There were no other adhesions except those mentioned to the parietal peritonaum and to the jejunum. It was a little roughened and puckered in places When it was laid open, the fluid was a little turbid and slightly blood-stained.

(b) Multiple Tumor Masses in Abdomen; Phantom Tumor Case L1.—Mrs. E., aged fifty-two years, admitted June 8, 1893, complaining of a swelling below the right jaw, pain in the abdomen, and of having vomited blood. There is nothing of note in her family history.

She has had eight children; four are living. She has never been a very strong woman. Fourteen years ago she had a submucous uterine fibroid, which was removed. Twenty-eight years ago she had a severe attack of typhoid fever. In October of 1891 she had diphtheria, which was followed, she says, by a lump at the angle of the right jaw. Shortly after this, too, she began to have occasional pains in the abdomen. In October, 1892, after a period of a good deal of excitement and worry, she had what was called brain fever, and was unconscious for two weeks. She was in bed at this time for nearly three months, partly in consequence of a carbuncle on the back.

She dates her present illness from about February of this year, when she had a great deal of oppression after eating, sometimes nausea, which were unusual symptoms. She also had at times straining at stool and a desire to go very frequently. The dyspeptic symptoms increased, though she never had severe pain. Four weeks ago, after a day or two of much dyspeptic trouble, she had an attack of vomiting after breakfast, and brought up a large amount of black, clotted blood. Her appetite has been poor, and she has had a great deal of eructation and pain after eating, relieved sometimes by the use of soda. For a week before her admission the right foot began to swell. Within the past six months a tumor mass has developed below the right jaw. Her condition on admission was as follows: Much emaciated; sallow complexion. Attached in front of the angle of the right lower maxilla is a group of enlarged glands, which extend over the jawbone on the cheek. The whole mass can be readily moved; the skin is a little reddened; the individual glands can be felt. The supraclavicular glands are not enlarged. The abdomen looks a little full. The right epigastric vein is much distended with blood; the left vein not quite so large. The current in both is from below upward. In the epigastric region to the left of the navel several nodular masses can be seen beneath the skin. There is no peristalsis visible. On palpation to the left of the navel, there is a solid, somewhat cord-like mass, about six centimetres in length, which extends in an oblique direction toward the axilla. It is very firm and hard, superficial, and feels as if attached to something beneath, as it is only partially movable. No gas is felt bubbling in it. Just above and to the right of the navel is a firm mass which is more difficult to limit and define. Midway between the navel and the ensiform cartilage is a soft, buttonlike mass which at intervals projects beneath the skin, and then suddenly relaxes with a sizzling sound. In a few moments it appears, hardens into an ovoid, resistant body about three centimetres in lateral extent, and then relaxes again with a sound of gas bubbling in it. The right inguinal region is occupied by a large nodulated mass feeling like a collection of lymph glands. The left inguinal glands are somewhat enlarged. She had no diarrhœa; the stools were liquid, grayish-brown in color. The rectal examination was negative.

The patient remained under observation for two weeks, and no essential change took place in the condition. There was no dilatation of the stomach. The tumor masses above described were very evident.

She left the hospital on June 30th, unimproved.

In many respects no case in the series was more interesting than this one, but a definite conclusion as to the seat of the primary disease did not seem possible. Naturally, with dyspepsia, belching, loss of appetite, and progressive emaciation, one suspected the stomach to be the seat of the malady, the more so with an account of an attack of vomiting in which she brought up a large amount of clotted blood. While under observation in hospital, the condition was not such as to justify putting her to the worry of a test breakfast. Not one of the tumors in the abdomen was apparently connected with the stomach itself, nor were there signs of dilatation. The tumors were rather like masses of enlarged lymph glands. The enlargement of the glands in the right side of the neck dated, she insists, from the diphtheria in October, 1891, but they had enlarged very much since February. The supraclavicular glands were not especially enlarged. Altogether we inclined to the opinion that there was a new growth in the stomach with extensive secondary lymphatic infection. By far the most striking feature in the case was the phantom tumor appearing and disappearing midway between the navel and the ensiform cartilage. Every minute or two it would emerge beneath the skin like a button, get firm and hard, assume an ovoid shape, and then, as one watched it, relax and disappear with a sizzling noise, which could be heard as well as felt. Of course such a tumor is only felt in connection with the tubular muscle of the gastro-intestinal canal, and in this case it was in all probability a limited portion of the coat hypertrophied on the proximal side of a constriction, caused either by a new growth at the attachment of the mesentery, or by some narrowing neoplasm in the wall itself. There was admitted yesterday to the ward a case in which you can study another remarkable phantom muscle

tumor. The young man has a well-marked history of ulcer, with vomiting of blood and hyperacidity of the gastric juice. The stomach is somewhat dilated, and in the epigastric region there appears at intervals, readily seen beneath the skin, an ovoid tumor, four to five centimetres in length, which lifts the abdominal wall definitely, and then in a few moments relaxes and disappears. When visible it is very firm and hard, and when relaxed it can only just be felt.

(c) Uterine Fibroids.—It speaks well for the differentiation of the cases in the hospital that, so far as I know, the following is the only instance of tumor associated with the female pelvic organs which came before me for examination. This, too, was rather by accident. As she had tuberculosis of the lip and tongue, the question was raised whether the abdominal condition was not due also to tuberculosis:

Case LII. Tuberculosis of the Lip and Cheek; Multiple Tumors in the Abdomen.-The patient, aged about forty years, was admitted for tuberculosis of the lip, tongue, and cheek. The abdomen was distended, and I was asked to see her to determine the nature of the masses which could be felt. She stated that they had been present for many years, and had never given her any trouble. The characters were very definite. The lumbar, iliac, the greater part of the umbilical, and the entire hypogastric regions were occupied by solid masses, which in the iliac regions presented several rounded movable prominences. The aterus was firmly fixed, and the whole pelvis appeared blocked with the masses. One point only was of interest in connection with the differential diagnosis of tuberculous peritonitis. In the iliac regions palpation was much softer, and the areas of resistance were separated by distinct intervals, and only on deep pressure could solid, uniform masses be felt. On percussion, there was a flat tympany, such as one finds not infrequently when tuberculous tumors are scattered about among the coils of intestines. Here the history, the character of the masses, and the persistence for more than a dozen years were quite sufficient for the diagnosis.

(d) Sarcoma of the Abdominal Wall.—The following case is uncommon in my experience and is worth placing on record. Not only was there a large, massive, subcutaneous tumor in the lower umbilical and upper hypogastric regions, but there were secondary nodules beneath the skin of the other parts of the body.

CASE LIII. Sarcoma of the Abdominal Wall; Numerous Subcutaneous Metastases.—Mrs. A., aged fifty-two years. The patient had been a healthy woman, had worked hard, and brought up a large family. For two months previous to my consultation with Dr. Atherton, of Toronto, August 24th, she had suffered with diarrhea and attacks of dyspepsia. The frequent movements have persisted. There was considerable nausea during last month, and vomiting occurred frequently after eating or drinking. She said she felt full, and could not hold nuch in the stomach. Within the past two months she had lost flesh rapidly and had become very weak. When first seen by Dr. Atherton, August 9th, the tumor about to be described was present. The examination by him of the pelvic viscera was negative. There was no cancer of the breast.

The patient was a medium-sized woman; looked emaciated, scarcely cachectic; was somewhat pale; tongue furred. Nothing of special moment about the circulatory or respiratory sys-

tems. The pulse was a little rapid, but of fair volume, somewhat irregular. Slight cough and some bloody expectoration, which continued until her death.

On exposing the abdomen there was seen a remarkable condition of the abdominal walls. While the portion above the navel looked normal, below this point there was a large mass occupying the lower umbilical, the whole of the hypogastric region, and extending into the inguinal regions. The skin was not discolored and showed the linear albicantes.

On superficial inspection it might have been taken for a somewhat unusual localized development of the fatty panniculus. On palpation the mass was felt to be firm, hard, involving the skin (which could not be moved separately), and presented a curious nodular feel, suggestive rather of bunches of lymph glands, or of the sensation given by touching the lobulated kidney of a sheep. With this there was also a feeling of massiveness and solidity, as if the tumor extended through the subcutaneous tissues. The mass sloped, as it were, gradually toward the periphery, and here the nodules were more isolated, and in lines running obliquely toward the false ribs. There were chains of these little nodules, like lymph knots. The whole surface of the body seemed tender and painful on palpation. She complained bitterly of pain after much handling of the mass. There were nodules also beneath the skin of the right breast, one or two in the right thigh, and several in other parts.

Dr. Atherton writes that he saw her for the last time on September 3d, and that she died on September 17th. The daughter states that diarrhea and vomiting continued, but no blood was passed at any time. For a few days before death "blue lumps," of about the size of a small bean, appeared in various parts of the trunk and extremities, which were tender and painful, like those seen by us.

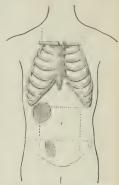

Whether or not this growth was primary in the abdominal walls is impossible to say in the absence of details which could be furnished by the autopsy alone. She had had gastro-intestinal trouble, but not such as pointed to malignant disease of stomach or bowel.

(e) Tumors of Doubtful Nature.—In none of the following cases did it seem possible to arrive at a satisfactory diagnosis. The salient points are as follows:

Case LIV. Dysentery; Two Tumor Masses in Abdomen .-Samuel T., aged about forty years, seen with Dr. F. R. Smith, November 17, 1892, complaining of a lump in the abdomen and diarrhea. His general health has been excellent, and his family history is good. He had typhoid fever when nine years of age. Ten years ago he was caught between two cars and injured about the hips and legs. He was laid up at this time for four months and had a dull pain in the right side, which has recurred at intervals, but never prevented him from working. Two months ago he appears to have had an attack of acute dysentery, frequent passages, and swelling of the legs. He was in bed for six weeks. As late as October 17th of this year he passed blood in the stools. He now has no swelling in the legs; appetite is good; bowels regular; and he has gained in weight and looks well, perhaps a little sallow. He has had no fever; tongue is clean. No enlargement of the lymph glands. In the right upper quadrant of the umbilical region, extending into the adjacent hypochondriac and lumbar regions, there is a firm, resistant mass, which reaches to about two centimetres below the level of the navel, and to the right can be felt as far out as the tip of the tenth rib. To the left it does not quite reach to the middle line. On bimanual palpation it is freely movable. It is not well felt below the ribs behind, but on deep pressure it can be pushed forward, and then is distinctly movable. It can be readily separated above from the liver, the edge of which is easily to be felt. In the hypogastric region, just above the pubes, and to the right of the middle line, there is a second tumor, feeling about the size of an orange, somewhat elongated. To the right it appears to have a definite

ridge-like edge. The percussion is everywhere resonant, and a clear note is clicited over both tumors, except for a short space to the right of the middle line over the one in the hypogastric region. Neither spleen nor liver dulness is increased. There is no dilatation of the stomach. The urine is clear and he has passed no blood, and there is no albumin; no tube casts.

The patient was seen again January 10th. General condition has been excellent, and he has been at work. There is no cachexia. The tumor masses previously noted were present with great distinctness. The lower one appeared to be scarcely so large as on previous exami-

The Fig. 37.—Situation of the tumors in carce-

nation. In the left inguinal region, about three centimetres from Poupart's ligament, there is a freely movable, subcutaneous nodular body about the size of a bean. The inguinal glands are not enlarged.

It did not seem possible to arrive at any conclusion as to the nature of these tumors. The strongest possibility seemed to be of their connection with the intestine, as he had had tenesmus, diarrhæa, and melæna, but the patient's excellent general condition and rapid improvement would seem to contraindicate new growth.

While preparing this lecture for the press this patient was seen (December 20th). His condition remains excellent and he has been steadily at work. The lower tumor is no longer palpable; the upper is still quite distinct, though smaller than at date of former note. Its position is unchanged.

The following case I regarded at first as tumor of the stomach, but on subsequent examination it seems to be extremely doubtful whether it is really in this organ:

Case LV. Tumor Mass in the Epigastrium of Doubtful Nature.-Kate H., aged forty-one years, admitted August 29, 1893, complaining of pain in the left side and swelling in the epigastrium. There is nothing of moment in the family history. She has been healthy with the exception of typhoid fever at twentyone and pleurisy last winter. She has had at times irregular cramps in the abdomen. For several years she has had dyspepsia, suffering with belching after eating and slight discomfort. Ten months ago she had an attack of severe pain in the epigastrium, with nausea and vomiting, and was in bed for a week. In the next two months she had four similar attacks, which lasted about a week. Some of these attacks, the doctor said, were due to gallstones. About two months ago she first noticed the swelling in the abdomen which is now present. She does not think it has increased in size. She never has been jaundiced; bowels are regular; passes a normal quantity of urine. Her chief complaint is of a dull pain below the left costal margin. She is a fairly well-nourished woman; lips and

mucous membranes are pale; tongue is coated. The abdomen is distended, chiefly in the epigastrium and in the right hypochondriae region, in which there is a smooth prominence. On palpation this corresponds to a rounded, hardened, somewhat nodular tumor, which in the middle line feels quite smooth and on the right side is more irregular. In the nipple line there is a marked ridge to be felt midway between the costal margin and the transverse navel line. The liver dullness begins at the sixth rib and continues directly into this prominent tumor mass. At first it was thought that this represented an enlarged liver, but on September 2d, on palpation, gurgling sounds were noted "in the prominent tumor in the epigastrium, and to-day it is everywhere resonant. The gurgling can be felt in this solid mass with the greatest distinctness. The tympany reaches as high as the base of the ensiform cartilage." Ewald's test breakfast showed the presence of free hydrochloric acid. This case interested us extremely from the remarkable simulation of the outline of the tumor mass to that of an enlarged liver.

On September 5th the following note was made: "There is a very distinct prominence below the costal margin in right epigastric and right hypochondriac regions. On palpation, a firm, resistant mass fills the upper zone of the abdomen, the outline of which resembles quite accurately that of an enlarged liver. Beyond the left parasternal line no very distinct edge is to be felt, but toward the right, as she draws a deep breath, there is a distinct nodular edge. The entire mass descends with inspiration. The resonance is not so extensive to day; it does not reach beyond the right parasternal line. After inflation the stomach tympany extends two fingers' breadth below the navel, and there is in the left epigastric and the left upper quadrant of the umbilical region the outline of a dilated stomach."

When resonance was first noticed in the mass below the ensiform cartilage we thought that possibly extensive infiltration of the stomach wall existed; but the patient has been under observation on several occasions since, and she has gained in weight, looks well, free hydrochloric acid is present in the gastric juice, and after inflation the resonance is not more tympanitic, and the stomach outlines seem somewhat below the mass. Altogether there was doubt enough to exclude the case from the stomach list, and I place it here among the miscellaneous tumors of doubtful nature.

(f) Aneurysm of the Aorta.—And lastly, not the least interesting of the miscellaneous tumors was a large sacculated aneurysm of the abdominal aorta.

Case LVI.—Lee K., aged sixty-seven years, admitted July 5th, complaining of a "fluttering lump" in the abdomen. With the exception of scurvy and rheumatism during the civil war he has been a very healthy man. He is temperate and denies venereal disease, but there is a distinct cicatrix just beyond the glaps penis.

Present Illness.—For three years he has noticed a lump in the abdomen, which for the past two years has been painful, and which he says has lately increased in size. He has a dull, steady, gnawing pain in the tumor itself, and more or less pain in the back. The pain and throbbing sometimes nauseate him, particularly after eating, and he has vomited twice in the past two weeks. Bowels are constipated; he has severe beadaches, and has had occasional bleeding from the nose. He is short of breath on exertion. Patient is a very vigorous, healthy looking man; well built; well nourished; musculature above the average. The conjunctive are a little watery and yellow; pupils are equal. Pulse regular, equal in both radials; the arteries thickened; can be rolled under the finger; pulse wave can not be obliterated. The brachial arteries are tortuous. The

examination of the lungs is negative. The apex beat of the heart is seen in the fifth interspace, just outside the nipple line; it is forcible and well defined. The sounds are clear; the first a little thudding, and both somewhat accentuated at the base.

Abdomen .- In the epigastric and upper part of the umbilical regions there is an irregularly rounded prominence, which pulsates forcibly and almost synchronously with the heart impulse. It has a transverse diameter of 8.5 centimetres; vertical nearly eight centimetres. It is perhaps a little more prominent to the right than to the left of the middle line, and on the right side almost obliterates the groove below the right costal margin. On palpation it feels smooth, yields to firm pressure, expands forcibly and in all directions. There is at times a distinct systolic thrill. The borders are everywhere rounded and it seems to dip down rather sharply just above the umbilicus. The tumor is not influenced by the knee-elbow position. The whole mass can be grasped in the hand and the expansion in that way very readily felt. It is unusually mobile laterally. It can be moved to the right, so that its left border is at the middle line. It can not be moved to the left quite so far, but far enough so that it pulsates under the left costal margin. The up and down movements are very slight; it is not influenced by respiration. There is dullness on light percussion over the top of the mass, and in a cir-

cle the diameter of which would be five centimetres. Beyond this there is tympany on all sides. On auscultation there is a loud systolic bruit heard everywhere over the tumor. There is no definite diastolic shock. The condition of the liver, spleen, and other parts of the abdomen is negative. The diagnosis of aneurysm of the abdominal aorta was made by Dr. Hewetson, under whose care the patient first came, and subsequently, when I saw him, the doubt arose in my mind, owing to the extreme mobility, whether it was really in the aorta, or whether it might not be connected with one of the branches-the tumor seemed remarkably mobile, and could be pushed so far from left

Fig. 38—Position of the aneurysm. The dotted outlines illustrate the extreme mobility. Case LVI.

to right. Dr. Halsted, too, thought that the tumor might possibly be in one of the branches; and as the patient consented he did an exploratory operation. The tumor was found to spring directly from the aorta just above the renal arteries. The pedicle of the sac was short and almost as wide as the aneurysm itself. It was thought better to leave the case to Nature than to attempt any measures to promote consolidation in the sac. The patient recovered rapidly from the operation and left the hospital in about ten days.

Aneurysm of the abdominal aorta is rare. This is the first one which has been under our observation since the hospital was opened, during which time there have been between forty and fifty aneurysms of the thoracic aorta in the wards. The diagnosis here was readily made; the tumor was so pronounced, so rotund, so expansile in all directions, and with a well-marked thrill and systolic bruit—no single feature of aneurysm was absent. The mobility alone was unusual; not one of the few aneurysms in this situation which I have seen presented such remarkable mobility.

A few weeks subsequently I saw in Montreal with Dr. Shepherd a patient who had progressive anemia and debility with great abdominal distention and pain. An abdominal tumor had been suspected, but the tympany and distention of the stomach and bowels prevented any satisfactory examination. She became more anæmic and died the day after I saw her. Through the kindness of Dr. Wyatt Johnston, I saw the specimen, which proved to be a large aneurysm of the abdominal aorta which had compressed the duodenum, causing great dilatation of the stomach. It had ruptured at one edge and hæmorrhage had taken place into the retroperitoneal tissues.

PROLONGED, NON-OBSTRUCTED LABOR IN THE FIRST STAGE; ITS MANAGEMENT.\*

By J. C. EDGAR, M.D.

It is with considerable diffidence that the writer appears before this society to read a paper upon the above topic, because he fears he has little that is really new upon the subject to offer to those especially interested in midwifery, or to the general practitioner. But it is because the successful management of a protracted first stage sometimes becomes such a difficult problem of midwifery practice that this subject for a short paper has been selected.

If the paper does nothing more than call forth a discussion that will enable us more clearly to appreciate the difficulties and the best means at our command for meeting and overcoming them, time will not have been lost.

Starting out with the understanding that we are to limit ourselves only to a consideration of delayed labor in the first stage as due solely to an absence, irregularity, or insufficiency of the expelling powers, the question that immediately confronts us at the outset is, "What do we mean by delayed labor?" What limits shall we set, the exceeding of which shall determine the transforming of a normal into an abnormal or delayed parturition. Normal labor may be defined as one in which the expelling powers are sufficient of themselves and without artificial aid to deliver a living fectus, the vertex presenting without undue exhaustion to either mother or child.

On the other hand, a given labor may be said to have exceeded the bounds of the normal condition and to have become delayed whenever, during any stage and in the presence or in the absence of expulsive efforts of the voluntary and involuntary forces, a considerable period of time clapses without marked progress being made, or when signs of exhaustion appear in mother or fœtus. † The amount of time that may thus elapse with safety to mother and fœtus is a varying quantity, a personal equation, depending upon many factors—as the strength of the individuals concerned,

the stage of labor during which the delay takes place, and the conditions present.

The accepted clinical guide of impending or present exhaustion and danger in both fœtus and mother is to be found in variations in the heart of each. In the fœtus the danger signal is furnished by increasing frequency and irregularity of the fœtal heart-beats, and this constitutes a reliable guide. In the mother an increasing pulse-rate, with or without a rise in temperature, and commencing alterations in the regularity of the uterine contractions, which may or may not be accompanied by nervous phenomena-as excitement, irritability, and so on-indicate trouble. One of the older writers upon obstetrics states that when delay occurs during the first stage "neither mother nor child is ever in danger (except in hæmorrhage or convulsions) on account of the labor.\* This was the teaching of thirty years ago-namely, that prolongation of the first stage is of no importance, provided the membranes be unruptured, the sufferings of the patient counting for little.

Another of the older writers (Churchill) states that labor is not tedious until twenty-four hours have passed, and, no matter how long the delay, interference is unjustifiable in the absence of a positive indication. We have, on the one hand, the teaching that "meddlesome midwifery is bad," that no interference is justifiable in the absence of a positive indication; and, on the other, that "delayed labor is bad," and that much subsequent damage may result to mother and fœtus if a lingering labor be allowed to continue, even when we are unable to clearly discern the accepted danger signals of impending exhaustion. It certainly may be stated without fear of contradiction that experience lessens the tendency to interfere during the progress of the first stage, and that it is "characteristic of over-anxiety to be always thinking it necessary to hasten the progress of dilatation" (Cullingworth).

On the other hand, it often becomes a grave question whether the general "wear and tear of a labor lasting more than twenty-four hours is not of itself a serious thing," and whether we are justified in "waiting with folded hands doing nothing until symptoms of mischief have actually arisen." †

It has recently been well said that it is the "bounden duty of the practitioner to avail himself of every means in his power to insure his patient an easy and short labor, with as little suffering as possible, provided only he is satisfied that the means he adopts are such as are not in themselves likely to prove injurious." ‡

I may state here that in the great majority of delayed labors in the first stage there is no real obstruction in the cervix. It may be stated, moreover, that in almost every instance the cervix will dilate readily enough, provided only there be sufficient strength to the expelling powers. From this we conclude, then, that the first principle of treatment is to find out the cause of inefficient uterine action and remove it. And often the cause is to be found in a distended bladder or rectum, or in excessive pain; and, as a spas-

<sup>‡</sup> Playfair, Loc. cit.

modically acting uterus is the chief cause of non-dilatation of the cervix, hence it is that relaxing drugs—such as chloral, gelsemium, and ether—are so often demanded. For convenience' sake, means destined for accelerating the first stage of labor may be divided into—

(a) Those means that we make use of and apply outside of the parturient canal, and

(b) Those that we make use of within the passages.

As a rule the remedies should be made use of in the order named, the latter class being avoided if possible.

(a) Means for Accelerating the First Stage of Labor that are applied without the Passages.—The simpler means should not be neglected. A tedious labor is often made to take on quite another aspect when the strength of the woman is improved by judicious feeding and stimulation, and securing for her two hours of rest or sleep.

As is well known also, encouraging the patient to be upon her feet and walk about at this time will strengthen the contractions when feeble, and especially after the rupture of the membranes will cause suspended contractions to set in again by the reflex stimulus of the presenting part upon the lower uterine segment and ring of the cervix.

With the squatting posture of the parturient and the use of Ahlfeld's birth-stool I have made no personal observations. A distended bladder will interfere with the proper contraction of the uterus by reason of its close anatomical relation, and a distended rectum as well may by reflex influences result in irregular and arrhythmical uterine contractions.

A valuable stimulant of labor pains is heat externally applied. A full hot bath or sitz-bath, or alternate hot and cold applications over the hypogastrium or sacral regions, are of great value. Perhaps no drug is oftener used as an oxytocic than quinine, although its action appears to be more of a stimulant to arouse the nervous system than a direct exciter of uterine action. Ergot as recommended by a few in the first stage we reject as unscientific and dangerous. Its use before the expulsion of the placenta is now absolutely forbidden in most of the large maternities of the world.

Since Playfair, in 1874, directed the attention of the profession to the use of chloral hydrate in the first stage it has come into almost general use. It gives most satisfactory results in very painful and cramp-like and irregular contractions with functional rigidity of the cervix, especially in primiparæ. Tincture of gelsemium in five to ten minim doses every twenty minutes has in our experience not given the same satisfactory results as chloral, although acting in somewhat the same manner. Antipyrine in fifteen-grain doses in irregular uterine action is greatly valued by some, but I have been unable to determine that it has any advantages over chloral. The same may be said of cocaine in two-grain suppositories or in twenty-percent, solution to the cervix.

Opium is of great value in diminishing uterine irritability. Although it stops preliminary pains and premature contractions, yet its secondary effect is to aid labor, as the recurring pains are strengthened, and the rest obtained to the parturient is of advantage.

It is generally advised that chloroform should be avoided in the first stage, and never used to the degree of narcosis. Its disadvantage rests in the fact that in sufficient quantity it temporarily arrests the contractions altogether. It is too strong and not sufficiently prolonged for this stage. The same objections do not apply to ether and the A. C. E. mixture.

In instances in which the severe pain and cramp-like action of the contractions appear to interfere with the progress of cervical dilatation we have found that pouring a small quantity of ether into an Allis inhaler and allowing the patient to inhale it, controls the suffering quite as well as chloroform does, and there is much less danger of inertia uteri being produced.

Manual frictions of the fundus uteri and expressio fœtus, although undoubtedly valuable methods in prolongation of the second stage, still have not been of much utility in the first stage until the cervical ring is more than one half dilated.

Manual frictions should be rotary in character, and timed with the commencing hardening of the uterus

Bearing down efforts on the part of the parturient are not generally considered to play any important part in the physiology of the stage of dilatation, still the increase of intra-abdominal pressure produced by voluntary efforts of the woman can in many instances be utilized to advantage. This is especially true after the partial dilatation of a soft cervix in multipare, the membranes having ruptured.

Many parturients under the above conditions, before the head enters the cervix or vagina and reflex stimulus causes a vigorous use of the voluntary muscles, diaphragm, abdominal walls, and pelvic floor, have no incentive to bear down and must be taught. They can to advantage be encouraged to do so, and when so instructed by the attendant, prolongation of the latter part of the first stage can in many instances be overcome, and the use of more complicated internal means for hastening labor avoided.

In electricity we possess one of the surest means for producing in a sluggish uterus, or in one the seat of inertia, strong, rhythmical contractions of the uterus. By its use we are enabled more closely to imitate Nature's method than by any other we know of.

In vertex presentations, the positive pole may be placed over the sacro-lumbar region, and the negative over the abdomen, care being taken to avoid the child's head. Another, but in my experience not so efficient a method, is to place sponge electrodes upon each lateral wall of the uterus.

In breech presentations, to avoid the fœtal head, the regions selected may be the patient's lumbo-sacral region and the nape of her neck. The lumbar electrode can conveniently be made of a copper plate, and held in place by a belt-or roller bandage; and for the abdominal, absorbent cotton, a sponge, or the hand of the operator.

Aside from the danger of increasing an already tetanic condition of the uterine muscular fibers, we believe we have seen asphyxia produced by setting up intra uterine or intravaginal attempts at respiration on the part of the foctus, and thus clogging the air passages with mucus and other foreign bodies. The remedy is not without its dangers.

Strychnine as a remedy preparatory to labor in the past few years has received considerable attention.\* It is especially applicable in multiparæ who in previous confinements have experienced prolonged and tedious labors, feeble and irregular uterine contrations, faulty contraction and retraction of the uterus, post-partum hæmorrhage, and severe after-pains. It is of especial service in women the subjects of general debility and want of tone in the voluntary muscles. A sixtieth of a grain of sulphate of strychnine is to be given three times daily, commencing four or even eight weeks prior to labor. If well borne the dose is in the last week to be increased to a thirtieth of a grain or even a fifteenth of a grain.

From observations in a number of selected cases in hospital practice, not only during pregnancy, but during labor and the puerperium, I find strychnine of real value. The plan pursued is to take all the multiparous waiting women in a hospital service and select therefrom all who have had abnormal previous labors due to feeble, irregular, or faulty uterine contractions, post-partum hæmorrhage, or severe after-pains, and those who have required the use of the forceps in conditions other than obstruction. These are all given a sixtieth of a grain of strychnine three times daily during the latter part of pregnancy until a week before the expected date of confinement, when the dose is increased to a thirtieth of a grain if well borne, and in some instances to a fifteenth of a grain.

In primiparæ suffering from tedious labor the hypodermic use of strychnine is employed. A sixtieth of a grain is given every fifteen minutes until a twentieth of a grain has been administered.

No ergot follows labor and a sixtieth of a grain of strychnine is given instead. The results so far are most satisfactory, and it certainly appears that we have in strychnine at least a valuable preventive measure for prolonged labor in the first stage.

(b) Means for Shortening the First Stage of Labor that are used within the Passages.—In having recourse to these means for hastening labor we presuppose that the simple external means for strengthening inefficient uterine contractions have failed, or that threatening exhaustion on the part of mother or child demands some prompter measure.

We moreover determine that no mechanical cause for delay exists, this fact being ascertained by a careful internal examination.

Among the simpler remedies for exciting the uterus to action and at the same time assisting in the softening of the cervix is the prolonged hot vaginal douche directed against the lower uterine segment. The douche is especially valuable in instances where, the os being only partially dilated, the lower uterine segment is forced down into the pelvis, and the walls of the segment become incarcerated between the head and the bony pelvis, thus causing an inflamed and edematous condition of the os.

If the internal examination reveals uterine contractions

that are spasmodic, irregular, and cramp-like, that even when the os is partially dilated the occurrence of a pain results in little if any protrusion of the bag of waters, then is it well to make sure that the membranes are separated from the uterine wall for a distance of at least two inches within the ring of the cervix. If adhesions exist here the clinical picture of the labor is often completely altered by their separation. To accomplish this many English writers advise the use of the gum-elastic catheter with a stilet. The little operation can more quickly, satisfactory, and with less danger of premature rupture of the membranes be performed with the finger introduced to the extent of two joints and swept around within the ring of the os.

In multiparæ the half hand can be introduced into the vagina to advantage. In primiparæ it will often be necessary to push the fundus backward, at the same time depressing it, and then, hooking the index finger into the cervix, the latter is drawn forward and downward and the separation accomplished. Whether separation of adhesions that interfere with dilatation is accomplished or not we do not know. Trenholme, of Montreal, first pointed out the clinical fact.

Artificial rupture of the membranes we only resort to in exceptional instances, such as hydramnios, for example.

No mechanical cause for delay existing, we have in direct internal uterine irritation a valuable means for increasing the expelling powers. Until recently this was mainly accomplished by the passage of one or more catheters or bougies, or the balloon catheter of Tarnier, between the membranes and uterine wall, and there allowed to remain. The method is too uncertain to demand further attention, as it is well known that it often fails absolutely or is too slow to be of value. The injection of from one to four ounces of sterilized glycerin high up between the membranes and uterus is a means which rarely fails to set up strong uterine action within an hour or two, provided the membranes be intact and the catheter can be inserted at least six inches.

One of the best-known means for the mechanical dilatation of the cervix, and at the same time exciting the uterus to contract, is the Barnes bag. We believe it to be one of the most valuable means at command if time be not wanting. Its action is self evident. It acts at the same time as a uterine exciter and a cervical dilator. Within the last two or three years substitutes for the Barnes bag have not been wanting. Some few years ago the Champetier bag for the induction of labor, and at the same time the dilatation of the cervix, was introduced to the notice of obstetricians.

At the twenty-sixth annual meeting of the British Medical Association, Dr. Ernest Herman and Dr. Herbert Spencer read papers stating their experience with this bag for the induction of labor. Folded up, it is by means of a pair of forceps introduced into the uterus empty, then partly filled with water, the forceps then being disarticulated and removed one blade at a time. The bag, as we see, is in the shape of an inverted cone, the apex lying in the internal os. A tube continuous with the apex has let into it a stopcock. The material used in its construction is non-

<sup>\*</sup> R. Bell (Brit, Med. Jour., p. 715, 1890) has recommended it highly.

elastic waterproof silk, so that a definite amount of water may be injected into it and no more. Its capacity is seventeen ounces, and the diameter of the base is three inches and a half. Consequently the os must be fully dilated for it to pass out into the vagina. The advantages of this bag over Barnes's, according to the English writers just quoted, are briefly as follows:

- 1. But one operation is necessary, as but one size of
- 2. Barnes's bag being elastic, no clear indication exists when it is pumped full. It also alters its shape according to the rigidity of the cervix.

Champentier's bag being inelastic, the reverse obtains.

- 3. Complete dilatation is claimed to be impossible with Barnes's bag. The Champentier dilates fully.
- 4. Both bags may displace the presenting part (vertex to shoulder, for instance), but with the Champentier this is claimed to constitute a less serious accident, for the bag acts as an efficient plug to retain the liquor amnii, and when once full dilatation is secured and the fœtus can be at once turned and extracted.

Acceleration of dilatation can be accomplished by traction upon the Champentier bag. In forty cases reported by Pinard, in which the Champentier bag was employed, in twenty-three dilatation was complete in from six to ten hours; in seven, from twelve to twenty-four hours; and in ten, from twenty-four to forty-eight hours. When completely filled the bag can be compressed to a transverse diameter of three inches; with two ounces of fluid removed it can be compressed to two inches and a half. Removing four ounces renders the bag shapeless.

It may be stated, on the other hand, that a good many accidents have already been caused by this type of dilator. In numerous reported instances the shoulder has been substituted for the vertex.

The writer reported such a case \* a year ago. Here the Champentier bag was used to accelerate a tedious labor, the vertex presenting and the head firmly engaged in the pelvis.

A modification of the Champentier bag has within a year been introduced. Although of about the same diameter at the base (three inches and a half), yet it is shallower, holds less water, and an arrangement of tapes permit of an indentation being produced in the base to contain the fætal head. Although so extensively used, as both of these bags now are in France and England, still we can not but look upon their action as unscientific and in many instances unnecessarily dangerous. We can not agree with those who state that even where displacement of the vertex into one or other iliac fossa, or even into the fundus uteri, does occur, such displacement is but a step toward one of the recognized methods of accomplishing delivery with the greatest prospect of success to mother and child-viz., by turning-and thus unintentionally aids the operator in his manipulations.

study of the case and the application of other means more

In the great majority of prolonged labors, by a careful

In 1892 the appearance of an extract from the fifth edition of the Text-book of Obstetrics for Midwives, by Professor E. Credé and G. Leopold, and which appeared soon afterward in this country, called forth considerable criticism. The following sentence especially has been taken exception to: "It is nothing less than criminal to try to assist in the stage of dilatation by attempting to stretch the cervix with the fingers and to push back the anterior lip of the cervix." No doubt this may be good conservative teaching as directed to midwives, but few if any obstetricians in this country would consider it anything but criminal to permit the anterior lip of the cervix to remain for any time between the head and pubes, and many of us would prefer the digital dilatation of the cervix in the first stage to the exclusion of such dilators as have originated from the French school of midwifery.

In suitable cases surely no harm can result to the lyingin woman if the aseptic hand is carefully used to assist dilatation of the os. Gentle manual dilatation is especially applicable in cases where the os is partially dilated, soft, and pushed low down in the pelvis.

To-day, in the face of sudden danger to either mother or child, we have two means whereby at any point in the first stage we may terminate the entire labor in thirty minutes or less. One is the deep cervical incisions of Dührssen, and the other the combination of operative procedures known under the general term of accouchement forcé.

Skutsch as late as 1887 recommended multiple incision of the cervix. The results of the operation are such as to cause the method to be almost entirely abandoned.

In late years Dührssen has proposed, not multiple, but four incisions of the undilated cervix, so made that when completed the os is wholly dilated, and the passage of the fœtus causes no further extension of the cuts. Dührssen has operated in this way upon thirty-five women. All the women recovered and only two children were lost. The operations were performed principally for eclampsia.

Accouchement forcé originally meant forcible delivery through an undilated or undilatable os. To day we usually understand the term as covering three operations-(1) manual or instrumental dilatation of the cervix, (2) version, and (3) immediate extraction of the child-and thirty minutes is ample time to accomplish all three, provided that when we commence the operation the portio vaginalis has already been drawn up into the body of the uterus.

The American Medical Editors' Association will hold its annual meeting at the Palace Hotel, San Francisco, on Monday evening, June 4th, under the presidency of Dr. C. H. Hughes, of St. Louis. A banquet will be tendered to the association by Mr. R. E. Queen, of San Francisco.

The Sims Statue for Bryant Park,-It is announced that the bronze statue of the late Dr. J. Marion Sims designed to be set up in Bryant Park has been completed. It is of heroic size and is said to be an admirable likeness.

An International Congress of Ophthalmology is to be held in Edinburgh on the 7th, 8th, 9th, and 10th of August.

scientific, the use of hydrostatic dilators, including Barnes's, may be dispensed with.

## BRIGHT'S DISEASE OF THE KIDNEYS,

WITH SPECIAL REFERENCE TO ALBUMINURIA AND URLEMIA, SO CALLED, INCLUDING PUERPERAL CONVULSIONS.\*

By R. C. M. PAGE, M.D.,
PROFESSOR OF GENERAL MEDICINE AND DISEASES OF THE CHEST
IN THE NEW YORK POLYCLINIC, ETC.

The subject to which I respectfully invite your attention this evening is somewhat comprehensive, and in order to introduce certain points for discussion you will pardon me for going over some ground so familiar to all.

Dr. Richard Bright, of Guy's Hospital, London, in 1827 first observed that albuminuria and dropsy were dependent upon renal disease, and since that time various renal affections have been grouped together under the name of Bright's disease of the kidneys. Various classifications have been made from time to time by different authors; but for the purpose of bringing out discussion on the subject before us, it will suffice to say that the disease may be acute or subacute and chronic. All forms appear to be of an inflammatory nature at the outset, whatever pathological changes may result ultimately, unless it be that form known as waxy (lardaceous, amyloid) degeneration. Both organs are usually affected, though one part of a kidney may be attacked differently from another.

Acute and subacute Bright's disease may be considered together as of the same nature. The latter most frequently results from the former, though in some cases the disease may be subacute in its course from the first—the difference depending a good deal on the condition of the patient at the time of the onset of the attack. In both forms the glomerules and tubules of the kidneys appear to be chiefly affected. Hence in these forms, dropsy and uræmic phenomena, as we shall see, are usually prominent symptoms.

Acute Bright's disease of the kidneys has a variety of other names, such as acute tubular or tubal nephritis, desquamative nephritis, parenchymatous nephritis, catarrhal, croupous, and diffuse nephritis, inflammatory dropsy, and the like. By others again it is termed glomerulo-nephritis.

In all cases there is perhaps a certain amount of predisposition, but whatever this may consist in, exposure to cold and wet are frequently exciting causes. Of toxic agents that bring about the disease when taken internally may be mentioned copaiba, turpentine, cantharides, the mineral acids, phosphorus, arsenic, lead, mercury, and nitrate of silver. Regarding alcohol, it is doubtful if the toxic action directly causes nephritis, but rather exposure incident to the intoxicated state, as the author has observed in several cases. Sometimes, as is well known, acute glomerulonephritis follows scarlet fever in children. It also occurs as a complication in diphtheria, epidemic cholera, measles, typhoid and typhus fevers, erysipelas, small-pox, and acute infectious diseases in general. It is observed sometimes in the course of pulmonary tuberculosis, articular rheumatism, gout, relapsing fever, acute lobar pneumonia, pyæmia, septicæmia, endocarditis, dysentery, carbuncles, and suppurative processes. In one case observed by the author at Bellevue Hospital many years ago, the disease was attributed by the late Dr. Austin Flint to extensive burns. In the chronic form of tubular nephritis severe chronic malarial poisoning undoubtedly gives rise to it.

What bearing has pregnancy on this disease? It probably acts more as an exciting cause where the predisposition already exists. According to Bartholow it occurs not oftener than once in a hundred and fifty times, but particularly in primiparæ and twin pregnancies. From personal observation the author is convinced it occurs much more frequently in twin pregnancies among primiparæ than others, and also among those who have become illegitimately pregnant and endeavor to conceal their condition by tight lacing and the like, thus greatly increasing the pressure on the kidneys and interfering with the renal circulation.

The disease occurs at all ages and among both sexes. But children and those under middle life are more subject to it, and young men are more frequently affected with it than women. And although a certain predisposition, consisting chiefly in general bad health, perhaps exists in all, yet it occurs sometimes among those who are apparently robust.

Brief reference to symptoms is necessary. Of these, pain in the back is regarded as very important by the laity; but in the author's experience never yet has he observed a case of Bright's disease of the kidneys that gave rise to pain. There may be a vague sense of tenderness on firm pressure in the back, but more than this such pain usually has no reference whatever to the kidneys, but it is simply lumbago to a greater or less degree.

In acute tubular nephritis dropsy is usually the first sign that causes the patient to seek medical advice. But before this is observed the patient, on close questioning, will probably admit that there have been certain uramic symptoms, so called, such as headache, drowsiness, insomnia, nausea, and even vomiting, paroxysmal attacks of dyspnæa or asthma, temporary disturbance of vision, and the like. This subject will be more thoroughly referred to presently.

The dropsy is due to several causes, and at first sight appears to be very easily explained. Chief among the causes of dropsy is imperfect renal function, on account of which there is diminished excretion of water, with corresponding increase of pressure in the capillaries. This does not account for it wholly, however, since dropsy does not necessarily follow ligation of the renal vessels with total suppression of urine. But, according to Cohnheim, there must also be present increased permeability of the walls of the vessels which allows the transudation of serum. What causes increased permeability of the walls of the blood-vessels early in the disease does not appear to be exactly known, but it is evident that later on such permeability is markedly increased by the loss of albumin and the anæmic condition. Should mitral disease supervene, as is often the case, that would also account in a measure for dropsy. This may be confined to a slight puffiness of the face, or the lower limbs may become much swollen and pit on pressure, especially over the tibia. In some cases the skin is distended almost

<sup>\*</sup> Read before the Society of the Alumni of Bellevue Hospital, February 7, 1864. For the discussion, see page 458.

to bursting, the lower limbs become so heavy as to interfere with walking, and the features so changed that even parents can not identify their own children.

The urine is scant and high-colored, being sometimes also smoky or even bloody. The normal quantity of urine passed in twenty-four hours is from forty-five to fifty ounces. But in these cases it may be reduced to half that amount, or a few ounces, or be even suppressed temporarily. The specific gravity varies, being sometimes normal, but it may be higher. According to Roberts, it may rise to 1.030 or even 1.065 without the presence of sugar. There are usually casts, and the urine is heavily loaded with albumin.

The presence of albumin in the urine is accounted for in various ways by different authors. Thus, according to some, it is due to its transudation through the walls of the renal capillaries from increased pressure. If rupture occurs, blood will also be found. After structural changes have taken place, the albuminuria will continue. In the author's opinion, Cohnheim's theory appears to be the correct one. According to that author, the albuminuria is due to changes in the epithelium of the glomeruli. As long as this epithelium is intact it supports the walls of the vessels of the glomeruli, thus rendering them impermeable and preventing escape of albumin. But in this disease the epithelia covering these vessels, or rather lining the capsule, undergo degeneration from inflammatory process, thus allowing the vessels to become dilated and permeable, with corresponding albuminuria. This becomes chronic should the structural change be not repaired. Albumin in the urine is not a sufficient sign by itself of Bright's disease of the kidneys, for it occurs transiently and in moderate quantity in connection with other conditions. Thus we find it sometimes in the course of dyspepsia and accompanying the grippe and many other diseases. It is also found in the urine of soldiers after exhausting marches, in that of athletes, etc. In these cases the albuminuria is probably due to nervous depression attended with temporary vaso-motor paralysis and dilatation of the renal capillaries. Diseases of the genito-urinary tract are also likely to give rise to the presence of a small amount of albumin in the urine, on account of the pus and blood that are likely to be passed, and great care should always be had in differentiating the disease.

Regarding tests for albumin, the ordinary heat and nitric-acid test and Heller's test are usually sufficient. One word of caution, however, is necessary, and that is, the urine should always be slightly acid in reaction, otherwise these tests for albumin fail.

Having briefly referred to the dropsy and albuminuria, uræmic symptoms now engage our attention. Besides those already referred to, such as drowsiness, headache, insomnia, nausea and vomiting, paroxysmal attacks of dyspnæa, temporary disturbance of vision, and the like, there may be convulsions and even coma. The explanation of these uræmic symptoms is a matter of dispute; in fact, the name itself is misleading if strictly interpreted. Probably the most commonly accepted theory is that they are due to urea retained in the blood. Frerichs believed that the urea be-

came converted into the carbonate of ammonium by decomposition from the action of a ferment in the blood. This theory, as is now well known, has been disproved by authors, Oppler, Zalesky, and others, on the other hand, maintain that all so-called uræmic phenomena, including convulsions, are due to retention in the blood of various extractive material, especially creatin and creatinin. It is quite likely, however, that imperfect elimination of all the extractives, on account of impaired renal function, giving rise to a vitiated condition of the blood in general, is the true explanation. So much for the chemical theory of uræmic symptoms. Of the supporters of the mechanical theory, Traube perhaps stands first. He considers that the so-called uræmic symptoms depend upon cerebral anæmia and pressure due to ædema. And it is worthy of note that uræmic phenomena are certainly more marked in proportion as dropsy is a prominent symptom. Other causes, including even cerebral lesions, have been brought forward and advocated by different authors.

Of late years, however, investigators have been looking more and more to disturbances of the circulation as the immediate cause of these symptoms. Just what such disturbances really are is not exactly known. But it is quite certain that in such cases, with uramic symptoms, there is increased arterial tension. This condition, with or without marked anæmia and œdema, culminates on a single occasion or repeatedly, as may happen, and is doubtless due to the vitiated condition of the blood, which also gives rise to varying abnormal sensibility of nerve centers. According to the degree of arterial tension and increased sensibility of nerve centers, as brought about by the vitiated condition of the blood, or what is generally understood to be the uræmic state, so do we have uræmic symptoms so called, such as have been already referred to. To sum up, then, we believe these phenomena are due to three factors: (1) Vitiated condition of the blood, (2) increased sensibility of nerve centers, and (3) increased arterial tension. It will be well to refer to these again when we come to the immediate treatment of convulsions and uramic symptoms in

The diagnosis of acute tubular nephritis is usually not difficult, resting chiefly on the presence of albumin and casts in the urine. So far as heart disease is concerned, in tubular nephritis, whether in the acute or chronic form, it is, perhaps, most frequently secondary, being some valvular lesion resulting from an endocarditis. For it is in this form of nephritis that there is a tendency to inflammation of serous membranes in general. In the chronic interstitial nephritis, on the other hand, hypertrophy of the left ventricle independent of valvular lesion occurs, and as to whether it is primary or secondary is still a subject for dispute among some.

The prognosis of acute tubular nephritis is nearly always favorable, especially if the patient be young and is seen early. Among the aged, however, there is little hope of recovery. The longer the albuminuria continues the more unfavorable the prognosis, and recovery can not be said to be complete until all signs of albumin have disappeared from the urine. Heredity is bad. In a tre cases of albuminaria, in the so called kidner of previous as it cours among primipane who are otherwise healthy, the prognosis is also good under skillful obstetrical management.

In the treatment of these cases I have never had any positively good results from counter-irritation over the loins, either in the form of cups or hot applications, except in the case of young children. I believe that in the nephritis following scarlet fever in children, for instance, the application of hot poultices to the loins does good. They are easily applied, and certainly afford relief and comfort to the patient when made large enough and kept dry, so as not to wet the bedclothes and undergarments. Cups, on the other hand, are disagreeable as well as difficult of application.

The kidneys being already congested, it seems to me that at first diuretics are contraindicated. On the other hand, if we get the bowels and skin to act vicariously we relieve the kidneys of their extra burden, and in this way help to avert the lesser and often serious uræmic symptoms. The chief reliance is to be placed on hydragogue cathartics. Of these one of the surest and best is the pulvis purgans, or compound jalap powder. It may be given in drachm doses and repeated without materially weakening the patient until the marked dropsy is lessened. Other hydragogues are recommended, and of these perhaps Clutterbuck's elaterium is the best. The author remembers that it was a favorite remedy with the late Dr. Austin Flint. But one very serious objection to this drug is its uncertainty, and valuable time may be lost while waiting for its effect.

In addition to hydragogue cathartics, diaphoresis would naturally appear to be indicated, but I would prefer the hot-air bath or other mechanical means rather than drugs for this purpose. In fact, this would be sufficiently accomplished, in most cases, by keeping the patient in bed or a warm room for a few days or a week. But in mild cases, or with patients who are already in a debilitated condition when attacked, catharsis and diaphoresis may be combined in Fothergill's pills, which I have often found to be invaluable (B. Calomel, pulv. digitalis, pulv. scillæ rad., āā gr. vj. Ft. pil. no. vj. Sig.: One every three hours until purging takes place). It is well to begin about noon to give these pills, so that, should necessity arise, a saline cathartic can be given early next morning to avoid any bad effect of mercury.

During the past few years I have been in the habit of giving large doses of the tinctura ferri chloridi, twenty drops in water every three hours. According to Roberts, iron acts well in these cases and hastens the disappearance of albumin from the urine. He, however, states that when begun too early it is apt to bring on a return of the acute symptoms. The author has never observed any such effect. Just how iron acts is not exactly known, but it perhaps aids in preventing deterioration of the blood as well as being curative to the inflammatory process in the renal tubules.

So far as diuretics are concerned, they are contraindicated at first, as already stated. Not until the bowels have been thoroughly moved and renal congestion somewhat re-

lieved, as evidenced by increased flow and more healthy condition of the urine, should diuretics be administered. Then they are of great benefit in washing out tubules that have become obstructed with epithelial débris. The best diuretic I have ever tried is the acetate of potassium and fresh infusion of digitalis (B. pulv. potass. acetat., \( \frac{7}{3} \) ss.; infusi digitalis, \( \frac{7}{3} \) vj. M. Sig.: Tablespoonful four times daily). After a week or more small doses of iron and some bitter tonic may be all that is required.

The diet should consist largely of milk or some of its preparations. In some cases I have treated these patients with perfect success while the diet was exclusively buttermilk.

For mild uræmic symptoms, such as dyspnæa, palpitation, headache, nausea, insomnia, and the like, a few drops of Magendie's solution is generally all that is needed, if given hypodermically. In the chronic interstitial form glonoin (nitroglycerin) acts well in relieving the headache by dilating the fibrosed arterioles.

But should uræmic symptoms become urgent, and convulsions be threatened or actually occur, what shall be done? Let us again bear in mind the factors that are necessary for the occurrence of these convulsions. They are: (1) Vitiated condition of the blood, (2) increased blood pressure, and (3) abnormally increased sensibility of nerve centers. We see at once that immediate treatment would rationally be directed to diminishing blood pressure and excitability of nerve centers, both of which can be quickly done, whereas the vitiated condition of the blood requires much time and attention to be altered appreciably.

In other words, the blood is to be improved gradually by the somewhat tedious process of repair, brought about by increased healthy nutrition, rather than corrected by the supposed sudden elimination of a poison. But it is certain that this latter notion has taken a very deep hold on the medical profession. Hence the routine treatment of drastic cathartics, diaphoresis, and diuresis, not to mention bloodletting. Even these severe means require time, so that the patient may succumb to repeated convulsions before the desired result has been accomplished. Moreover, such drastic measures may do harm by weakening and annoying the patient without doing the least good, unless it be occasionally in very acute cases.

Bloodletting is mentioned first as a means of averting danger in uræmic poisoning, as it is perhaps the oldest. It is still practiced by some, but it should be confined to sthenic and acute cases, if indeed it be practiced at all. But be it remembered that it is not by eliminating a poison that bloodletting acts in these cases, but by diminishing blood pressure. Its effects are quickly felt and, being directed to factor No. 2 in a sure and certain way, it breaks one link in the uræmic chain, so to speak, and to that extent it is a speedy and sure means. But, inasmuch as we possess a remedy that will produce an equivalent effect without loss of blood which may be much needed later on, why bleed at all?

Chloroform is mentioned next in order, and is, perhaps, more generally used now in these cases than anything else. May 12, 1894.]

It acts by blunting nerve centers and so is directed against factor No. 3. There is no doubt chloroform will arrest convulsions, and is thus indicated in the immediate treatment of uramic poisoning. But chloroform is a dangerous drug, and, moreover, the convulsions often return as soon as the chloroform is withdrawn. In two cases that I now have in mind I sat up all night with the patients, one in Bellevue Hospital and the other in the country, in Connecticut. In both the convulsions returned as soon as they partly came out of the influence of the drug, and they both died. My belief then and now is that too much chloroform hastened their death, or was partly to blame for it. One word about ether. I have myself observed such alarming symptoms brought on by giving ether, even in the eclampsia of pregnancy so called, and gynæcologists in this city give such fatal results from its administration in renal diseases, that I am disposed to let it severely alone-and my earnest advice to others is to do the same thing. Among children, chloral administered by the rectum is said to act well. I have had no experience with it and do not even know the dose, but should be disposed to limit it to two grains and repeat in two hours if necessary.

Opium has been recommended by high authority, as is well known, with or without bloodletting. Like chloroform, it blunts nerve centers, thus rendering them less responsive to the irritation of disturbing elements, while in proper doses it does not fatally depress the heart. Moreover, its effects are more lasting than those of chloroform. For these reasons, as Loomis justly observes, it is preferable to chloroform, both being directed to factor No. 3. But opium alone meets only the indication relating to irritability of nerve centers. To reduce blood pressure at the same time, which can readily be done, it should be combined with bloodletting or some means equivalent. In chronic cases, however, where the blood is thin and poor, the patient feeble, and there is no hope of recovery, as well as for the lesser uramic symptoms, opium, judiciously used, has no equal in the experience of the author.

A word as to pilocarpine. This drug has been, and still is, used in these cases, but not so much for its effect on the circulation as with the old idea of eliminating a poison through the skin, owing to its great diaphoretic properties. But it is an exceedingly dangerous cardiac depressant, besides causing strangulation of the patient sometimes, owing to the greatly increased flow of tough saliva. It is very improbable that pilocarpine eliminates poison sufficiently in a few minutes to ward off convulsions. It probably acts, in such cases, by lowering arterial tension, if, indeed, it is beneficial at all. In general treatment, however, or during the interval, so to speak, pilocarpine in small doses acts well by stimulating the functions of the skin.

In a limited number of cases I have given pilocarpine and morphine in combination, hypodermically. A grain of hydrochloride of pilocarpine is dissolved in eighty minims of Magendie's solution of morphine, of which ten minims are injected. The morphine holds the heart up to its work, while the pilocarpine prevents over blood pressure, besides causing profuse diaphoresis.

carpine combined in solution. The case was that of a boy, perhaps twelve years of age, suffering with a severe attack of bilious remittent fever, and was seen with me by Dr. H. Koplik. In spite of large doses of quinine the temperature rose to 105° F., the urine became almost suppressed, bloody, and highly albuminous, and the patient comatose. Within an hour after the hypodermic injection of the mixture the boy became conscious, perspiration was profuse, and the case went steadily on to recovery. In this particular case, diaphoresis was perhaps more indicated than lowering of arterial tension, but I quote it to show how successfully morphine and pilocarpine combined in solution may be given in those cases.

Veratrum viride is the remedy to which allusion was made when speaking of its taking the place of bloodletting. Here we have a remedy that acts like bloodletting. but without loss of blood. In other words, it diminishes arterial tension but does not eliminate a poison.

It appears that Clark, of Oswego, this State, first used veratrum viride in large doses in these cases, but he gave it by the mouth. Just here let me say that when symptoms are urgent the hypodermic method is the only trustworthy one, when effects are needed without delay and with certainty. Hence the great advantage, as was first observed by Dr. W. H. Johnston, of Birmingham, Ala., of giving this remedy hypodermically. Now we are all aware of the prejudice existing against the use of veratrum viride in large doses, and especially hypodermically. Given alone it is undoubtedly a dangerous remedy, nearly as much so as pilocarpine, perhaps. But in conjunction with opium it appears to be perfectly safe and certainly very efficacious, as I have satisfied myself by personal experience. Only Norwood's tineture should be used. Just why Norwood's tincture should be better than any other tincture or preparation of veratrum viride I do not know, but it is the incontestable fact. The plan is to give the usual dose of morphine (M v-x of Magendie's solution) hypodermically, and with the same instrument, as soon as it can be filled, from five to ten minims of the tincture of veratrum viride. That is the same as ten to twenty drops of the tincture. Brandy or whisky should be at hand in case of cardiac depression, but I have never observed any alarming case of it. Not only do convulsions cease, but they do not recur for some time. During the interval, as a prophylactic measure, veratrum in moderate doses by the mouth acts well. Even in epilepsy the bromides act very much better, in my experience, when combined with veratrum. It is the opinion of the author that, after three years' experience, the conjoined opium and veratrum hypodermic method is the correct treatment of the severe forms of so-called uræmia-at least the best yet discovered.

Should we have to deal with uramic coma, perhaps hydragogue catharsis and diaphoresis by well-known methods is our sole means at hand. Thus, in the case of a patient at Bellevue Hospital many years ago, I gave him, by order of Dr. Flint, two grains of Clutterbuck's elaterin. He was about thirty-five years old, and was made to swallow by manipulating the larynx. But it may be administered by In the autumn of 1883 I first gave morphine and pilo- means of a tube. I have tried to give elaterin hypodermically, but, being a resinous substance, it appears to be impossible. The remedy in the above-mentioned case proved to be successful, and the patient left the hospital afterward much improved, though not cured. After a complete cure of acute tubular nephritis, the patient should take care for a long time not to bring on a relapse by acts of imprudence, such as intemperance and, above all, exposure to cold.

Should uramic symptoms occur during pregnancy, the same immediate treatment is indicated, for the so-called eclampsia of the pregnant woman is perhaps identical with the so-called uramic convulsions. They both yield to the opium and veratrum treatment. But, in the case of pregnancy, the question of bringing on labor is to be considered.

Chronic Bright's disease of the kidneys may be one of three typical forms, according to the renal anatomical elements involved: (1) Tubules, (2) interstitial tissue, and (3) the blood-vessels. Of course, there may be mixed cases in which all these elements named may become involved.

- 1. Chronic tubular nephritis may be chronic in form when first observed, and in some of these cases I have reason to believe that there is latent tuberculosis and even hereditary predisposition. I have known, even among the wealthy, several members of a family to have chronic tubular nephritis, while others, or their children, would suffer with pulmonary tuberculosis, scrofula, and the like. In others it follows one or more acute attacks, especially among those who have bad hygienic surroundings, or are in a condition of marked lowered vitality. The kidney is large, smooth, and white, the changes occurring chiefly in the cortical portion. It affects both sexes at all ages. The uræmic symptoms and dropsy are more prominent than in other chronic forms. The urine is generally scanty and high-colored, being also loaded with albumin. Casts of various kinds are also observed. Inflammation of serous membranes is more likely to occur in this form than in the other; and dyspnæa, besides being uræmic and paroxysmal, may be due to eddema of the lungs. Cardiac complications are more likely to result from valvular lesions following endocarditis than simple hypertrophy of the left ventricle.
- 2. Chronic interstitial nephritis gives rise usually to the small, red, contracted or cirrhotic kidney. This is due chiefly to shrinkage of the cortical portion and tissues between the pyramids. The disease is invariably chronic, and is generally met with in men rather than women, and those at middle life or past. Gout, rheumatism, syphilis, intemperance, and lead poisoning are given as causes of this disease, but often the ætiology is obscure. The urine is abundant, of a low specific gravity, and often contains but little albumin. The casts are usually granular or hyaline. Simple hypertrophy of the left ventricle, with marked accentuation of the second sound in the aortic interspace, is generally observed. By some this hypertrophy is thought to be due to resistance in the renal circulation, but it is more probably caused by general fibrosis of the arterioles throughout the body. Apoplexy of the retina and even of the brain is likely to occur in this form for obvious reasons.
- 3. Lastly, there may be waxy (lardaceous, amyloid) degeneration of the kidney. This condition is generally sec-

ondary to some pre-existing wasting disease, as caries of bone, phthisis, syphilis, and the like. The materies morbi is carried to the kidneys by the arteries, so that the afferent vessels of the glomerule become affected first. Subsequently the whole Malpighian corpuscle becomes involved. Tubular nephritis generally supervenes if the patient lives a sufficient length of time. The treatment of these cases is chiefly symptomatic. In general, however, severe measures are not indicated, as they may be in acute tubular nephritis. For that reason I prefer Fothergill's pills to drastic hydragogue cathartics. In chronic interstitial nephritis the headache is often best relieved by glonoin, as already stated. A liberal diet of milk, or some of its preparations, is frequently beneficial. In a case treated by me at the Polyclinic Hospital recently the albumin entirely disappeared from the urine under a milk diet alone, though the patient had suffered with chronic albuminuria for several years. The invalid should remove, if possible, to a warm, dry climate. Of the three forms of chronic Bright's disease, tubular nephritis offers the most hopeful prognosis. But recovery is rare, and the disease is apt to return on the least provocation, even after the patient is thought to have been cured.

31 West Thirty-third Street,

#### RUPTURES OF THE MEMBRANA TYMPANI.\*

BY CHARLES SHAFFNER, A.M., M.D.,
OCULIST TO THE PRESEYTERIAN HOSPITAL,
MEMBER OF THE COLLEGE OF PHYSICIANS, PHILADELPHIA.

RUPTURE of the membrana tympani is by no means a rare occurrence, all the aural surgeons in this section of the College of Physicians no doubt having had some experience with this accident, and myself having had recently a case of it in my private practice, so I have thought a few remarks on this subject would be of interest to the members of the section in otology.

Rupture of the membrana tympani presents such sudden and marked symptoms at its occurrence as to call the attention of the patient to his ear and to excite his fear and apprehension. Many cases are reported in medical literature, and quite a number have presented themselves to my notice during past years, mostly some time after the occurrence of the accident and for the purpose of obtaining a critical opinion as to the amount of damage sustained by the ear for the purpose of obtaining a pension from the United States, or to discover the probability of the patient obtaining success in a suit at law for damages.

Causes.—The peculiar position of the membrana tympani, a very thin fibrous membrane, exposed to sudden changes of pressure both on its inner and outer surface, as well as its position almost on the outer surface of the body, causing it to be easily injured either by design, accident, or meddlesome interference, is the reason for our cases of rupture. The common causes in my own experience have been the rarefaction or condensation of air on either the

<sup>\*</sup> Read before the Section in Otology and Laryngology of the College of Physicians of Philadelphia.

inner or outer surface, or the entrance of objects into the external auditory meatus, or extension of fractures of the petrous bone. Several cases have presented themselves to my notice many years after their occurrence due to sudden concussion of the air in one ear while the patient was exposed with the ear near the mouth of a large cannon which had been exploded rather suddenly, and which he had just loaded; again I had infantry soldiers, whose regiment was supporting a battery of field pieces, and who were compelled to lie down in front of the cannon and allow them to be fired over their prostrate bodies. These patients both gave histories of sudden rupture of the membrana tympani and presented ears with more or less damage to hearing for the purpose of securing pensions. I have also seen a case where the patient had been a marine diver, who went down to the bottom of deep water to help build a foundation of a bridge. I could not say in his case that the membrana tympani had been ruptured, but there was some loss of hearing. Again the case which called forth these remarks was a rupture of the membrana tympani caused by either rarefaction or condensation of air, produced by the patient's blowing his nose rather forcibly in efforts to clean some sticky scabs out of it (cleansing the same side as the ear affected), as he was suffering from a mild chronic ozena. Several cases have been seen which were caused by sudden blows of the fist or open hand over the opening of the external auditory meatus, either in sport or in fighting in earnest. The old-fashioned habit of nurses and school teachers of boxing the ears of unruly children as a punishment has been the rather frequent cause of rupture of the membrana tympani, but happily this has been done away with. Under this cause comes the frequency of rupture of the membrana tympani in hanging, whether judicial or suicidal, its occurrence being reported in almost every case. It also has occurred in severe spells of vomiting, in sneezing, and in whooping cough, but in these latter cases Roosa thinks there must have been some attendant catarrh of the tympanum as its indirect cause. Perhaps almost every aurist has caused rupture of the membrana tympani himself while suddenly and rather forcibly inflating a chronically diseased ear with a Politzer's bag; but in these cases there must have been some chalky or fatty change in the membrana tympani to cause it to rupture so easily.

Almost any body of proper size to pass down the external auditory meatus to the membrana tympani can cause its rupture in the hands of some meddlesome person or a surgeon unskilled in handling instruments. A woman may be scratching an itching meatus-a very bad habit by the way-with a hairpin, when she herself, or some one striking her elbow, will cause a rupture. I have seen a case where a young farmer fell while crossing a wheat-stubble field, when a stalk of the stiff stubble caused a severe rupture of the membrana tympani by entering his ear when his head struck the ground. Roosa mentions a case of a young man getting a straw in his ear while ascending a ladder, and thus rupturing his membrana tympani. Picking ears with tooth-picks, or by young scholars with sharp lead pencils, are reported as causes of this accident. Po-

a syringe with a long, sharp nozzle, and in efforts to extract foreign bodies. Receiving a wave in the ear in sea-bathing we see in Philadelphia as a rather frequent cause of rupture.

Fractures of the petrous portion of the temporal bone sometimes extend into the membrana tympani and thus rupture it. In fact, the hamorrhage accompanying this accident and running out of the external auditory meatus is the acknowledged sign of fracture of the skull in the neighborhood of the tympanum. One such case fell under my own notice many years ago. A train in which I was traveling struck a young girl, about ten years old, who had been walking on the railroad track, and tossed her body to one side. As this passed my car window and excited my curiosity, when the train stopped I went back with the crowd to see what damage had been caused, when I saw the dead body lying beside the track with a moderate hæmorrhage coming out of one ear. I diagnosticated fracture of the base of the skull running to the petrous portion of the temporal bone.

A case of rupture of the membrana tympani from a fracture of the bone of the skull was lately reported to the Ophthalmological Section of the College of Physicians. The young man was shown who had received a blow on the side of his head by getting it caught between projecting timbers from one car and the car in front. Here there was a hæmorrhage from the external auditory meatus, and ruptures were seen. In these cases, if there is much hæmorrhage, it comes from the diploe of the bone and not from the membrana tympani.

The diagnosis is not difficult if the ear is seen within a week or so of the accident, but there is generally so little scar left that it is almost impossible to tell it after any length of time, as the aurist is often asked to do. If the case is seen immediately after the accident a slight hæmorrhage occurs in or from the external auditory meatus and a ragged linear laceration is discovered in the membrana tympani with its edges covered with clotted blood. It does not remain long of linear shape, but soon is dragged by the radiating fibers of the membrana tympani into a round or lozenge-shaped opening. I have usually discovered in looking at these rather recent cases nothing but an intensely congested membrana tympani with an irregular-shaped clot of blood sticking fast to the membrana tympani, which was Nature's way of closing and sealing the opening.

The position of the rupture may be in any portion of the membrana tympani, but it is most frequently seen in the anterior lower fourth near the situation of the cone of light; next most frequently in the posterior lower quarter, and then parallel to the handle of the malleus, either anterior or posterior to it. In my case where a man ruptured his membrana tympani while blowing his nose the rupture was linear in shape, anterior to the handle of the malleus, and somewhat in a parallel direction to it. Julius Veit, of Munich (Med. Abhandl., 1892), cites forty-three ruptures seen among six thousand five hundred aural cases (0.66 per cent.). Four of these, produced by penetrating bodies, had two in the anterior inferior quarter, one in the anterior superior quarter, one in the middle line below center. litzer mentions its having been caused by a careless use of | Seven were from extension of fractures of the bones of

the skull and from concussions, thirty-two were from sudden rarefaction of air in the external meatus, twenty-seven of these from blows to the ear, four by detonations, one by a blow during bathing. Of these thirty-two of rarefaction, the rupture was in the anterior half in twenty-three cases, four superiorly, eleven inferiorly, and five in the posterior half.

Politzer says: "I have more frequently seen ruptures in front of the handle of the malleus than in the posterior half of the membrana tympani," and quotes Zaufal as performing seven experiments on the cadaver and producing rupture in the anterior half six times. He agrees with Zaufal's experience that an obliquely placed membrana tympani causes the instrument to slide forward on to the anterior portions.

The prognosis is usually very favorable, unless the rupture is accompanied by concussion of the internal ear, or by suppuration of the membrana tympani and middle ear, by myringitis, or by fracture of bones. Politzer says: "In most cases disturbances of hearing caused by traumatic ruptures disappear completely, so that the function becomes normal again."

Schwartze, in his Pathology of the Ear, page 90, says: "Simple ruptures, without deeper injury of the ear, usually heal in healthy individuals and under proper care in from a few days to a few weeks, sometimes leaving a cicatrix and sometimes not." In my case, where rupture was caused by blowing the nose, hearing came up from hard contact to about watch one foot, the hearing in the other ear being about three feet, and the rupture healed up in a week. I have usually given a favorable prognosis to sufferers from rupture of the membrana tympani due to a slap over the ear, and dissuaded them from entering legal proceedings against their friend or enemy. As to the applicants for pensions, it is impossible to declare that the loss of hearing is due to a rupture of the membrana tympani; but it is safe to swear that there is loss of hearing at present existing, which may have been caused by rupture of the membrana tympani, accompanied with concussion of the

Of course, if a suppuration of the middle ear has been set up, the prognosis is graver, and the prognosis is grave in ruptures from fractures of the bones of the skull.

Symptoms.—The patient comes to you with a history of a sudden loud report in the ear, accompanied by a sharp, severe, piercing pain. Fainting, staggering gait, giddiness, and severe loud tinnitus soon set in, giving the patient more or less of a shock and impressing his mind with the fact that something serious has happened to him. There is great loss of hearing in the affected ear, which may not hear the watch even on hard pressure, or the tuning fork aerially or by contact. In a few hours these symptoms gradually subside, leaving an uncomfortable feeling, almost painful, in the ear, and more or less tinnitus; my last patient also had some autophony for several days. Tinnitus and distress may continue for a week or so. Ruptures caused by clean bodies and in healthy ears do not usually have long-continued symptoms; but, unfortunately, few such bodies are aseptic, and they are therefore apt to set up suppuration. All aurists know how difficult it is to keep open an

incision made in the membrana tympani by clean, sharp instruments; as Nature is so quick and determined in healing these up, they have to be burned with the electro-cautery; so the rupture is soon filled and covered over with a clot of blood, under which the rupture soon heals, myringitis goes down, and hearing begins to return, while the blood clot either falls off or is carried off to the periphery with the growth of the membrana tympani, and so out to the wall of the external auditory meatus. An irregular scar remains for some time where the rupture was, and gradually disappears. In unfavorable cases the laceration remains patulous, the middle ear becomes infected with germs, and a severe and prolonged suppuration sets in, which may even end in the mastoid.

Treatment.-The surgeon had better be an observer of Nature's process of healing in the average case of rupture of the membrana tympani and not be too meddlesome. In fact, an expectant plan of freatment will in most cases be the best; certainly in the early stage of healing it is the best, until you are sure suppuration has been set up or severe myringitis has come on. Some surgeons syringe the ear with warm water, but I consider this bad practice unless pus is present. My own habit is to keep clean cotton in the orifice of the external auditory meatus, to keep the ear warm and prevent the entrance of dust and germs from the air; to use some counter-irritant back of the auricle-say, compound tincture of iodine-partly as a placebo until the proper time for more active treatment arrives, and partly as a revulsive; to give purges by the mouth and nervous sedatives, especially potassium bromide, hoping to lessen the tinnitus. Then, after a few days, when healing has gone on, inflation with Politzer's bag always improves the hearing, lessens tinnitus, and removes autophony. My own case was immediately improved by the first inflation. I should advise no efforts being made to remove the clotted scab, as it had better be left to the care of Nature, even for weeks. The use of soft and sloppy food is of benefit in the early stage, as the motion of the jaw and the anterior wall of the external auditory meatus serves to excite pain. Occasionally a leech or two on the tragus is needed to subdue severe inflammation.

251 SOUTH THIRTEENTH STREET.

## A CASE OF

# SARCOMA OF THE CILIARY BODY AND CHORIOID.

CLINICAL HISTORY AND OPERATION.
BY DAVID WEBSTER, M. D., ETC.

PATHOLOGICAL EXAMINATION AND REMARKS. By H. DAVISON SCHWARZSCHILD, M. D., ETC.

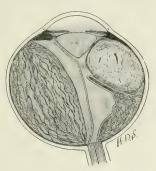

CLINICAL HISTORY.—Helen H., aged ten years, was admitted to the Manhattan Eye and Ear Hospital, September 20, 1893. Her vision was at that time, R. E.  $\frac{2}{13}$ —; L. E., perception of light only. She gave a history of a blow with a bottle over the left orbit about a year previously. This did not give her any trouble at the time. Her attention was not called to anything wrong with her eye until she went to the country in July, 1893. Her parents then noticed that there was something wrong with the left eye, but

as she did not complain of any pain in the eye it gave them no concern. They brought her to the hospital because they saw a spot on the eye. They were surprised when told that she could not see out of that eye. The family history is good, none of her relations so far as is known ever having suffered from malignant disease. Upon examination, a tumor was found occupying the nasal side of the vitreous chamber. It seemed to spring from the ciliary body and chorioid. Posteriorly it extended far back toward the optic disk. Anteriorly it pressed the nasal portion of the iris forward. The iris at its nasal periphery was so thin by this pressure that it was in parts almost entirely absorbed. The tumor was of a dark color generally, with darker striæ running along its surface. There was also detachment of the retina contiguous to the tumor.

After consulting with my colleagues, and obtaining the consent of those responsible for the child, I enucleated the eyeball with the assistance of Dr. Schwarzschild, to whom I am indebted for the pathological examination.

The patient was discharged after remaining in the hospital three days. She was under observation for several weeks thereafter, and up to the time she was last seen there was no return of the growth.

Pathological Examination.—The eye was placed in Müller's fluid; it remained there six weeks and was then removed. I subsequently made a frozen horizontal section to bisect the tumor. This could be distinctly felt as a bulging mass through the sclera, which was intact.

Macroscopically.—The growth is ovoid in shape, measuring eight millimetres in its short and twelve millimetres in its long diameter. The latter intersects the optical axis at an angle of fifty degrees. The mass is of firm consistence, grayish in color and moderately mottled. It lies in apposition anteriorly with the ciliary body and contiguous portion of the iris to the distance of two millimetres and a half; externally is bounded by the chorioid, having therefore a curve similar to that of the sclera, and internally it abuts against the retina. The lens is triangularly compressed through pressure. The retina is detached partly by the new growth, but principally by the fluid occupying the vitreous chamber. The aqueous has a gelatinous appearance; the anterior chamber is of normal depth.

Microscopically.—The tumor consists of a fibrillar basement substance, blood-vessels, large round cells in vast numbers, and but few spindle cells. Neither variety is arranged in alveoli. There is a moderate amount of pigment visible throughout the growth. Glioma cells are not present. The tumor arises from the ciliary body and anterior five eighths of the chorioid, and is bounded internally by the retinal pigment layer, which is adherent to the mass but separated from the retina. The diagnosis is therefore that of a lightly pigmented, large round-celled surcoma

of the corpus ciliare and chorioid. The form of tumor described, as a rule, possesses greater consistence and is less malignant than the small-celled variety. The retina over a small area is normal; this corresponds to that portion which in the recent state was adherent but became detached post mortem. Over the greater surface, however, it is thickened. The membrana limitans interna is in parts separated; when present it is distorted. The layer of nerve fibers, ganglion cells, and the finely granular (molecular) layers are replaced by connective tissue. Bloodvessels are noticeably absent and the supporting tissue is hypertrophic. The rods and cones are swollen and changed in shape. Those portions of the detached membrane which lie in apposition are held together by a loose connective-tissue formation which, being infiltrated by exudation, presents at first glance the appearance of multiple cysts. The fluid contained in the cavity of the globe and anterior chamber is albuminoid in character and devoid of fibrin and cells. The chorioid is the seat of an exudative inflammation. The nerve is unchanged. The iris is atrophic throughout, particularly so, however, at its origin in the vicinity of the sarcoma. The ciliary body in its entirety presents evidences of a pre-existing mild serous cyclitis; the cornea and sclera are normal.

The feature of interest in this case is the occurrence of a sarcoma in a child at the early age of eleven. The intra-ocular malignant neoplasm to be expected at any time from the period of birth to the fifth and exceptionally to the twelfth year is the glioma, a retinal growth. Contrarily disposed, however, is the sarcoma, which occurs in adults commonly between the ages of forty and sixty, and, as an ætiological factor thereto, a history of traumatism is usually obtainable. This is exemplified in the case under consideration. In glioma, however, although there is no exciting cause apparent, it is nevertheless evident that a certain congenital morbid predisposition constitutes an underlying element in its genesis. The susceptibility of children to the development of sarcoma of the uvea is remarkably slight, since, even after the reception of severe injuries, we are compelled to recognize the extreme rarity of its occurrence. Glioma and sarcoma occur in the eye as primary tumors; they spread to neighboring structures through continuity via the paths of least resistance—i. e., the preformed passages. Metastatically they develop in organs in different parts of the body; conversely, malignant tumors in remote regions have been observed as rarities developing in the chorioid through metastasis. In all cases of intraocular neoplasm of malignant nature enucleation should be performed at once, as it is only by prompt surgical interference that the spread of the growth may be arrested. Small sarcomata of the iris, it is true, have been removed by iridectomy; but, as isolated neoplastic cells which have invaded adjacent structures are not removed thereby, the growth recurs. Substitutive operations for enucleation in similar cases, such as evisceration with or without the insertion of an artificial vitreous, are to be condemned, firstly, on account of their inefficacy, and secondly, as sympathetic ophthalmia may be induced thereby. After the growth has perforated the globe and the orbital tissues have been involved, in addition to enucleation, exenteration of the orbit becomes necessary,

The prognosis of intra-ocular malignant neoplasm is dependent upon the early removal of the eye.

## NEW YORK MEDICAL JOURNAL.

A Weekly Review of Medicine.

Published by D. Appleton & Co.

Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 12, 1894.

#### THE OPIUM HABIT.

Dr. Patrick Hehir, a surgeon-captain in the Bengal Army and lecturer on medicine and pathology in the Hyderabad Medical School, has made a report, dated February 13, 1894, to the Royal Opium Commission, of England. Dr. Hehir appears to have had great opportunities of observing the effects of the habitual use of opium, and, if we may judge from his report, either the evils of habitual addiction to opium have been overdrawn, or Indian opium is much more inoffensive than the drug with which American and European physicians are familiar, or the Indian constitution is remarkably tolerant of its action, or, finally, the author of the report is singularly mistaken.

Dr. Hehir states that he has filled a number of offices in India during the past twenty years and has had many opportunities of observing the use of opium under almost every conceivable circumstance, but most of his experience has been gained in his capacity as a private practitioner of medicine. The habit of opium-eating is very prevalent in Hyderabad; Dr. Hehir estimates that twelve per cent. of the Mohammedans, seven per cent. of the Hindus, and five per cent. of the Pariahs and other classes are addicted to it; in round numbers, there are, he thinks, 1,400,000 opium-eaters in a population of about 11,000,-000. The average amount of opium consumed by each devotee of the habit is about eight grains a day, half in the morning and half in the evening. In some families opium is given to all the children, even to those who are only a month old, while in others it is given only to those of the children that have shown a predisposition to intestinal ailments, general weakness, or susceptibility to fever, cold, or some other infirmity. Among the laboring classes it is given to the infants to keep them quiet while their mothers are out at work.

The general conclusions which Dr. Hehir draws from his observations and from his own experience, for he has been an opium-eater himself, are that opium used in moderation enables a person to do more work on less food and with less sleep in a given length of time than he would be able to do without it; that it endows him for the time being with an unwonted cheerfulness and disposition to work; that it never produces any organic disease whatever, its chief ill effect being constipation; that it calms the irritated mind, allays the ruffled feelings, reestablishes the mental equilibrium when it has been destroyed, conquers resentment, is opposed to impulsive action of any kind, and keeps emotional displays within bounds; that instead of shortening life it increases its duration; and that instead of increasing the mortality it diminishes the death-rate.

known. Dr. Hehir says that he has known a diabetic to take two hundred grains a day for seven years, and yet be none the worse for the habit. The man was emaciated, but, says the author, it would have been phenomenal had he not been, for he was losing eleven ounces of glucose daily. Indian opium is said to be characterized by its poverty in morphine, by containing a large proportion of an antiperiodic principle, and by its richness in those unknown constituents which give rise to the pleasurable sensations experienced by the opium-eater. Indian opium is always pure; at least it is never sophisticated fraudulently. It is obvious that we can not reason from these observations on the use of a weak and peculiar opium upon a community living under conditions very different from our own as to the effects of the opium of commerce on Americans and Europeans living at home; nevertheless, Dr. Hehir's contribution to the literature of opium must be said to be very valuable.

#### THE ABSORPTION OF IRON.

In the April number of the Journal of Physiology there is an article on this subject by Dr. A. B. Macallum, associate professor of physiology in the University of Toronto. The article is largely founded on the author's own experiments, but it is also in great part critical. Experiments on guinea-pigs and other animals have shown to the author's satisfaction that the intestinal mucous membrane absorbs inorganic iron compounds to an extent varying with the nature of the compound and with the quantity of it given. When the dose is small, he says, absorption occurs only in that part of the intestine, a few nches in length, which adjoins the pylorus, but when a large quantity is given at one time the process of absorption may be carried on by the mucous membrane of the whole intestine. In the former case the result, he thinks, depends on the complete precipitation, in the form of hydroxide, of the iron of the salt unabsorbed in the thoroughly mixed bile, chyme, and pancreatic juice; and in the latter case the large amount of the iron salt first destroys the alkalinity of these fluids, and then the excess of the salt unaffected and remaining in solution undergoes absorption.

The intestinal epithelial cells transfer the absorbed iron to the underlying elements at once when the quantity absorbed is small, but when a large amount is absorbed the epithelial cells are found to contain some of it. Though some of the subepithelial leucocytes of the villi appear to carry part of the absorbed iron into the general circulation, probably the more important agent in the transfer of the inorganic iron compound from the villi to other parts of the body is the blood-plasma. Marfori's albuminate and the commercial "peptonate" of iron, when administered to guinea-pigs, seem to stimulate the leucocytes to invade the epithelial layer of the intestinal villi. Of the inorganic compounds belonging to the "chromatin" class, that present in egg-yolk (Bunge's hæmatogen) undergoes absorption in the intestine of the guinea-pig and in that of Amblustoma. In these animals, but more especially in the latter, The beneficial effect of opium in cases of diabetes is well after they have been fed with the yolk of egg for several days,

the cytoplasm of the liver cells yields decided evidence of the presence of an inorganic iron compound belonging to the "chromatin" class and derived from the yolk. The mode of absorption of yolk "chromatin" is obscure, but the process appears to be connected in some way with the absorption of the fat with which the iron compound is closely associated in the yolk.

#### PERSISTENT SNEEZING UNDER CHLOROFORM ANAESTHESIA.

In the April number of the Indian Medical Gazette Dr. Chalke, of Berhampore, relates the case of a Hindu man, thirtyfour years old, who was admitted into the Municipal Hospital for a staphyloma of the cornea with disorganization of the eyeball which required extirpation. He had also granular lids. It was decided to remove the eyeball, and the author administered chloroform. When the patient was completely anæsthetized Dr. Wilkins applied a blepharostat. Almost immediately the patient began to sneeze, and, after sneezing persistently for about two minutes, recovered consciousness. In the meantime the speculum had to be removed. The patient was again put under the influence of chloroform and the instrument adjusted, when the sneezing began anew and he recovered consciousness as before. For a third time this sequence of occurrences took place. The operation was postponed, and after a lapse of four days the patient was anæsthetized again with chloroform, the inhalation of which was preceded by a hypodermic injection of cocaine. He was anæsthetized very rapidly and the speculum adjusted, but sneezing began at once and he recovered consciousness. He was chloroformed again and a four-per-cent. solution of cocaine was dropped into the affected eye at frequent intervals as a local anæsthetic. On this occasion no sneezing occurred on applying the speculum, and the operation was performed without further trouble.

In explanation of the persistence of the reflex which gave rise to the sneezing under full anæsthesia, the author adduces a hyperæsthetic state of the sensory nerves of the conjunctiva and cornea, giving rise to an impulse transmitted to the mucous membrane of the nose through the nasal nerve, a branch of the ophthalmic. He thinks that this hyperæsthetic area was not completely anæsthetized until cocaine was used in addition to the general anæsthetic.

#### MINOR PARAGRAPHS.

#### THE PROGRESS OF CREMATION.

At a recent meeting of the French Society for the Propagation of Cremation, as we learn from the *Progrès médical* for April 7th, an account was given of the progress of cremation in various countries. The secretary general of the society, M. Georges Salomon, said that the United States headed the list of countries in which cremation was practiced, and added that in various parts of the country crematories had been erected. Progress had been made in England also. In regard to Germany, there was a certain amount of continuous agitation at Frankfork, and there was a small crematory at Offenbach. Organizations in Berlin, Munich, Leipsie, Stuttgart, Nuremberg,

and Stettin had petitioned for permission to exercise cremation. In Switzerland there had been very decided progress. In Italy the number of towns in which cremation was practiced was still increasing. In Sweden the practice was thus far only tolerated; it was carried on in Stockholm and in Göthenburg. As for Denmark, seven incinerations had taken place in Copenhagen between the 1st of January, 1893, and the 3d of February, 1894. In Austria a society was actively pursuing its purpose of obtaining permission to practice cremation. In regard to Holland, the cremation society was still under the necessity of cremating its members in foreign parts.

#### THE CRAIG COLONY FOR EPILEPTICS.

Following the example of some European countries, New York State has provided for the establishment of a colony for epileptics, Governor Flower having recently signed the bill authorizing the Craig colony in Livingston County. There are five managers of the colony, each of whom serves for five years, without compensation. The Governor has appointed Dr. Frederick Peterson, of New York, Mr. W. H. Cuddeback, of Buffalo, Dr. Charles E. Jones, of Albany, Mrs. C. F. Wadsworth, of Geneseo, and Mr. George M. Shull, of Mount Morris. At a recent meeting of the managers Dr. Peterson was elected president and Mr. Shull secretary of the board. The Assembly has appropriated \$140,000 to purchase the land, erect buildings, etc., and meet the necessary expenses.

#### GASTROPLICATION.

In the Centralblatt für Chirurgie for April 21st there is a preliminary communication by Professor Brandt, of Klausenburg, concerning an operation for dilatation of the stomach which he calls gastroplicatio. The abdominal cavity is opened, and the wall of the stomach is then folded upon itself and the fold made permanent by means of sutures passed through the peritoneal and muscular layers. The author gives the notes of a case in which this operation was performed. The patient, a woman, twenty-six years old, was able to leave her bed on the tenth day. Nothing is said of her subsequent condition. The author remarks that a similar operation was advocated in the same journal in 1892, under the name of gastrorrhaphy.

## AN ECCLESIASTIC'S REPUTATION SAVED BY THE OBSTETRICAL CALENDAR.

Lyon médical quotes from Vratch a condensed version of a story published in the Médecine russe to the effect that a certain Russian curate's wife was confined on December 23d. This occurrence led the villagers to complain to the archbishop, alleging that she must have conceived on the 25th of March (Good Friday), but a physician allayed the scandal by showing by the obstetrical calendar that fecundation might have occurred a week or more earlier.

#### THE LANCET AND THE LATE DR. BROWN-SÉQUARD.

Under the subheading Complimentary Quotation the Lancet's Paris correspondent states that an obituary notice of the late Dr. Brown-Séquard published in the Progrès médical was an almost literal translation of the correspondent's own remarks that appeared in the Lancet.

#### MORE NEWSPAPER MEDICINE.

Frankfort, and there was a small crematory at Offenbach. Organizations in Berlin, Munich, Leipsic, Stuttgart, Nuremberg, ician whose life was "seriously despaired of" six months ago,

has now fully recovered his strength and gained twenty-five pounds in weight "at" no corresponding loss of energy.

#### ITEMS, ETC.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending May 8, 1894:

DISEASES.	Week end	ling May 1.	Week ending May 8.			
Diceases.	Cases.	Deaths.	Cases.	Deaths.		
Typhoid fever	6	0	7	0		
Scarlet fever	147	11	157	13		
Cerebro-spinal meningitis	()	0	7	3		
Measles	239	14	296	15		
Diphtheria	202	50	199	61		
Small-pox	16	5	20	3		

The New York State Board of Health.—It is announced that the secretary, Dr. Balch, has resigned, and that Dr. J. S. Barnes, of Watkins, has been elected to succeed him.

Changes of Address.—Dr. W. Freudenthal, to No. 943 Madison Avenue; Dr. T. Lewinski, to No. 16 Jefferson Street; Dr. Edward N. Liell, to No. 109 West Eighty-fourth Street; Dr. C. A. von Ramdohr, to No. 45 Irving Place; Dr. J. Wolfson, to No. 302 Montgomery Street, Jersey City.

The Death of Dr. A. A. Lutkins, of Jersey City, took place on Wednesday, the 9th inst. The deceased was a graduate of the Medical Department of the University of the City of New York and had for many years been a busy and highly respected practitioner.

### Society Meetings for the Coming Week:

Monday, May 14th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medicohistorical Society (private); New York Ophthalmological Society (private); Society of Medical Jurisprudence, New York; Lenox Medical and Surgical Society (private), New York; Boston Society for Medical Improvement; Gynæcological Society of Boston; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private); Baltimore Medical Association.

Tuesday, May 15th: Illinois State Medical Society (first day—Decatur); Pennsylvania State Medical Society (first day—Philadelphia); New York Academy of Medicine (Section in General Medicine); New York Obstetrical Society (private); Ogdensburgh, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Societies of the Counties of Kings and St. Lawrence (annual), N. Y.; Baltimore Academy of Medicine; Hampden, Mass., District Medical Society (annual—Springfield).

Wednesday, May 16th: Ohio State Medical Society (first day —Zanesville); Illinois State Medical Society (second day); Pennsylvania State Medical Society (second day); Harlem Medical Association of the City of New York; Medico-legal Society, New York; New York Academy of Medicine (Section in Public Health and Hygiene); Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark).

THURSDAY, May 17th: Indiana State Medical Society (first day — Indianapolis); Missouri State Medical Association (first day—Lebanon); Ohio State Medical Society (second day); Illinois State Medical Society (third day); Pennsylvania

State Medical Society (third day); New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Mass., Society for Medical Improvement (private).

FRIDAY, May 18th: Indiana State Medical Society (second day); Missouri State Medical Association (second day); Ohio State Medical Society (third day); Pennsylvania State Medical Society (fourth day); New York Academy of Medicine (Section in Orthopædic Surgery); Baltimore Clinical Society; Chicago Gynæcological Society.

SATURDAY, May 19th: Clinical Society of the New York Postgraduate Medical School and Hospital.

## Retters to the Editor.

A FOREIGN BODY IN THE RECTUM.

JOLIET, ILL., May 1, 1894.

To the Editor of the New York Medical Journal:

Sir: I noticed in the Journal of April 28th an article entitled A Peculiar Case of Foreign Body in the Rectum. Several years ago a similar peculiar case came under my observation. I was then assisting a well-known surgeon in one of our Western cities, and have since scarcely thought of the occurrence until reading the above-mentioned article.

There came one morning an impatient rapping at the outer door of the reception room long before time for office hours. Upon opening the door I discovered an old, gray-haired man, bent nearly double, as I thought, from old age, but soon learned that the man was suffering intense pain. He was as pale as death, and his face wore that well-known drawn look that comes from such a cause. He told his story in a broken manner. It seems that the morning of the day before he had been greatly annoyed with protruding piles, and in a fit of desperation had whittled a stick some ten inches long to the diameter of about two thirds of an inch, with which he pushed back the piles. He experienced so much relief from this operation that he let go the stick, thinking to leave it there for a while, but the peristaltic action of the bowels drew it entirely out of his reach, and it kept on working upward, finally getting into the sigmoid flexure.

The physicians in his own little village had told him that he must die, that there was no help for him. He had heard of the ability of the doctor whom I was assisting, and made haste to reach him as soon as possible, coming twenty miles by rail in that agonizing condition.

The doctor doubted his ability to reach the stick, but went to work at least to try, with visions of a laparotomy floating through his mind.

He gave a warm rectal douche and then proceeded to probe for the stick, having no idea as to its length, thinking probably to procure a body three or four inches long; but imagine his surprise, when he at last was enabled to seize it with the small obstetrical forceps and gradually work it out, to see such a long piece.

He made the remark that if any one had told him of such a case, or had he read it, he would not have believed it. But the stick can be seen to-day among his curiosities.

The man went home happy as a man who had received a reprieve when about to be hanged. He had been at death's door, but the door had been closed against him for a while at least.

The mystery was the length of the stick and the rapidity with which it was traveling.

MARGARET E. SIMMONS, M. D.

#### A LOST MANUSCRIPT.

30 West Thirty-fifth Street, May 7, 1894.

To the Editor of the New York Medical Journal:

Sir: A manuscript has been jost bearing the following name: A Retrospect of Ophthalmology from Nadir to Zenith, with Special Reference to the History of Cataract.

This constituted the opening ophthalmic lecture in the new building of the Post-graduate Medical School and Hospital. It will be published under the amended name, A Retrospect of Cataract from Nadir to Zenith. Editors are respectfully requested not to accept a paper with the above-mentioned or a similar name from any one but the undersigned.

H. DAVISON SCHWARZSCHILD, M. D.

## Proceedings of Societies.

SOCIETY OF THE ALUMNI OF BELLEVUE HOSPITAL.

Meeting of March 7, 1894.

The President, Dr. Frederick Holme Wiggin, in the Chair.

(Concluded from page 504.)

Prolonged, Non-obstructed Labor in the First Stage; its Management.—Dr. J. CLIFTON EDGAR read a paper with this title. (See page 582.)

Dr. E. H. Grandin said that the drugs had been very few which had proved useful in his hands in tedious labor not due to any pelvic deformity or to malposition of the child. He had tested all of them, and had come back to the use of the older ones. Chloral, in fifteen-grain doses every half-hour up to forty or sixty grains, he still found useful, particularly where the cervix was rigid and where the uterine contractions were not normal because of nervous irritability. He did not like to give opium to the lying in woman or the puerperal woman, for the reason that he was desirous above all things of keeping the intestinal canal active. He could not recall a case where he had given opium to the parturient woman. Where it was desirable, however, codeine should be used. He had found quinine very valuable, given by the rectum in doses of thirty grains, and he preferred to give it in hot solution, because it was then more quickly absorbed. It certainly intensified the pains, acting, as he thought, rather as an irritant to the uterus than through the nervous system. He had had no experience yet with strychnine in obstetric practice, but would certainly give it a trial.

Passing to the use of mechanical means for overcoming inertia uteri, he said he had absolutely no use for the dilators which had been exhibited. He could conceive of the Champentier dilator doing a great deal of harm, and it was unnecessary, because the human hand would accomplish everything which this would do, and without the attendant danger. He did not approve of the use of glycerin and stilettes in the uterus, because we desired especially to maintain the integrity of the membranes in order to have the conditions favorable for version in case this operation should be forced upon us. The injection of glycerin might cause a premature rupture of the membranes, and the same objection applied to the introduction of a stilette. Where mechanical means were required, he had for years favored the use of the hand, and the results so obtained and reported by him, he thought, were fully as good, if not better,

than those secured by other means. In a former paper, in which he had advocated the use of the hand, he had unfortunately used the term accouchement forcé, which had led to the erroneous impression that he had advocated forcible dilatation of the cervix and lower uterine segment. As, however, he had stated that he had taken from thirty to forty minutes to dilate the cervix, this should have made it sufficiently evident that he was not using forcible dilatation. His method was to introduce one finger after another until the entire hand was within the uterine segment; then, if there was an indication for immediate delivery, and if the membranes had not ruptured, he would immediately seize the foot, perform version, and extract. He wished, therefore, to emphasize the fact that we did not need in this country any of these rubber dilators, and in this opinion he was in accord with the reader of the paper. The band could effect dilatation of the rigid cervix under deep chloroform anæsthesia. He preferred chloroform for this purpose, because it relaxed the uterine spasm more than ether.

Dr. Charles Jewett said that he had unfortunately come too late to hear all the points made in the paper. He thought the cases under discussion could be divided into two classesviz., (1) inertia of the uterus; (2) painful but non-progressive labor. In the first class active interference was not ordinarily called for. There was no objection, however, he thought, to measures which did not interfere within the passages-e.g., postural measures, hot and cold compresses over the abdomen, enemata of glycerin, etc. With regard to the second class, the trouble was generally to be looked for in the upper or active segment of the uterus. We were dealing not so much with obstruction as with irregular and inefficient pains. The two drugs upon which he had relied chiefly were chloral and morphine or some preparation of opium. These drugs, especially the latter, would generally do one of two things-regulate the pains and at once establish normal labor or put the patient to sleep. In the latter event, after a few hours' rest, the delivery, as a rule, was rapidly completed. He had had a very satisfactory experience with opium; its bad effect on the intestinal canal could easily be counteracted.

Regarding the mechanical measures, he agreed with the last speaker that the hand was the best instrument. Dilating bags were clumsy, and often inefficient, and could not be used as intelligently as the hand. Great care, too, was needed to avoid much force. He introduced the fingers one after the other, and finally the thumb. After inserting the whole hand, he closed the fist. This considerably enlarged the dilator, and was the most dangerous part of the process. It was at this time that there was the greatest risk of lacerating the uterus, if the operator was not careful to gauge the force employed correctly. Rupture of the cervix was, however, unnecessary if proper care was observed. The intra-uterine injections of glycerin he thought a justifiable and a valuable measure for accelerating labor. He had also employed Duhrssen's incisions in a few cases, but reserved this procedure for desperate cases where the slower methods were not applicable. He had not used it until the os internum had become obliterated, at which time four incisions, carried to the vaginal junction, would often give sufficient space to admit of rapid delivery. In one case, however, in which he had employed this method the posterior incision had been extended upward by a laceration into the uterus, but not into the peritoneal cavity. Regarding the question of anæsthetics, he would like to hear further opinions as to the relative effect of ether and chloroform as relaxants. Recently he had been using ether as the obstetric anæsthetic in his bos pital service, and there had been several cases of post-partum

Dr. MALCOLM McLEAN said that he would speak on the subject of Barnes's dilators. He was not at all willing to discard these instruments, and for a reason to which the previous speakers had not alluded. In the use of any mechanical means for dilatation of the cervix it must be remembered that there were two demands in practice-viz., (1) for very rapid delivery -misnamed accouchement force; and (2) where delivery did not need to be so rapid. In the former there was not much time for any of the interior rubber dilators, except to start the dilatation. In his judgment it was better to begin with them and end with the ordinary manual methods as already described. In certain other cases where there was no such hurry, he thought we should imitate Nature very much more closely than by the manual method by causing a softening of the fibers of the cervix uteri. It was well known that there was a process of softening of these tissues by a change of nutrition produced by pressure, just as there was a change in the consistence of other tissues produced by constant pressure. Divulsion of a muscle was one thing, and a gradual, slow pressure causing absorption and relaxation was another. By the latter, the pressure of the bag of waters-that very valuable adjuvant in parturition-was imitated. If, therefore, the Barnes's dilators were properly applied, and left for two or three hoursand this could be done if a properly constructed dilator was employed-it would be found that the whole vagina instead of being comparatively dry would be bathed with mucus, and that the cervix would be soft and in a favorable state for the subsequent operative measures. He was sorry to see that there was a tendency to throw aside this instrument. The speaker then exhibited a dilator of his own construction. It had no pocket as in the older Barnes's bag, was easy of introduction, and consisted of a double bag. The instrument having been inserted, one pocket should be filled with a measured quantity of sterilized water. Within an hour this bag would become loose, and, if constructed as on the plan of the older instrument, it would have to be removed and a larger size inserted. With his instrument, however, it was only necessary to dilate the other compartment of the dilator, and within two hours the dilatation of the cervix would be equal to that obtained by the widest stretching out of the fingers. By this contrivance we obtained by elastic pressure that continued and steady dilating force which could not be maintained with the human hand. He had used this method and this instrument for the past ten years and with the utmost satisfaction, and Dr. Barnes had himself stated that he considered it an improvement on his original instrument.

Dr. W. Evelyn Porter thought the paper a very valuable one for every practitioner, because the delays occurring in this stage of labor often caused great waste of time, to say nothing of the effect on the patient. Regarding the use of drugs, he preferred chloral hydrate to all others, and this seemed to be the opinion of most obstetricians. As a mechanical means of dilatation he favored the use of the Barnes's bag as modified by Dr. McLean. With the older instrument he had experienced the usual difficulty in keeping the bag in position long enough to secure satisfactory dilatation. When there was any difficulty in using any such instrument, manual dilatation might be resorted to until a larger sized bag could be easily introduced.

Dr. Edgar said, regarding the use of the catheter and intra-uterine injections of glycerin tending to cause rupture of the membranes, that he did not think this accident should occur if reasonable care was exercised. He had omitted to mention in his paper that he had found enemata of pure glycerin exceedingly useful in accelerating the first stage. While the glycerin suppositories would not act under two hours, or perhaps not even then, two or three drackurs of pure glycerin

when injected into the rectum often acted very promptly. He wished to go on record as quite agreeing with Dr. McLean in not discarding Barnes's bag; he only wished to emphasize the fact that such instruments as those of the French school were sometimes dangerous, as shown by the case he had reported in which a vertex presentation had been changed to a shoulder. He also quite agreed as to the value of starting the dilatation with the bag before doing manual dilatation of the cervix when rapid delivery was demanded, as in case of eclampsia. The Barnes's bags were of the most value in causing the disappearance of the supravaginal portion of the cervix. Only a few nights before he had been called in consultation by a member of this society to a case of eclampsia at the sixth month and a half. The woman had been having her second convulsion when seen. Morphine, chloroform, and veratrum viride had been used to control the seizures; several ounces of glycerin had been immediately injected to the fundus of the uterus, and a Barnes's bag inserted in the os as soon as dilatation permitted. By these means the supravaginal portion of the cervix had been made to disappear partially, and when this had once been accomplished, the woman was completely anæsthetized, and by means of rapid manual dilatation and version the uterus had been emptied in forty minutes.

The Dietetic Treatment of Phthisis, -Dr. Henry P. Looms read a paper with this title. He began with a statement that in his opinion judicious feeding was more potent in the treatment of consumption than either climate or medication. Milk and meat, he said, were the articles that in themselves furnished the most heat-producing and force-producing elements with the least tax upon the digestive functions. Milk should not be given in quantities of more than half a pint at a time, and that amount should be sipped during a period of ten or fifteen minutes. If large amounts were given daily, limewater should be added in the proportion of a tablespoonful to half a pint of milk. An elegant way of giving milk was to administer it scalded, with the addition of Seltzer water. Patients who could not take milk might take kumyss or matzoon. If the digestion was particularly weak, the milk might be peptonized, but on prolonged use peptonized milk was apt to become very distasteful. As a rule, from two to four quarts of milk should be taken in the course of twenty-four hours. Meat was to be given cooked or, if large quantities were to be taken, in the form of the expressed juice. With a squeezer, about half a pint of juice could be obtained from a pound of meat. The meat should first be broiled over a brisk fire, and then cut up into moderately small pieces, but no heat should be applied to the juice after it was squeezed out. If it was desirable to warm the juice after it had become cold, that could be done by placing the cup containing it in hot water. Beef-tea should never be used in consumption. Another excellent preparation of meat was that known as scraped meat-balls. The material was secured by scraping the pulp from steak, either with a fork or with a meat-scraper, so as to leave the stringy part behind. The scrapings were to be rolled into small balls, broiled over a quick fire, and served hot with pepper and salt or Worcestershire sauce. The scrapings might also be used raw, spread between thin slices of bread. An excellent meat powder might be prepared by chopping boiled beef into fine pieces, drying it over a water bath, and grinding it fine in a coffee mill. Meat powder, prepared in this way or by various other methods, might be added to the liquid articles of diet. Alcohol and codliver oil came next to meat and milk as articles of food for consumptives. From a dietetic point of view, pulmonary consumption might be divided into three stages, which were not to be understood as corresponding to stages of the lesions characteristic of the disease: 1. That in which the digestion and appe-

tite were not affected. 2. That of incipient digestive disturbance, lasting until the time when the stomach would no longer tolerate solid food. 3. That lasting from the end of the second period until the time of death. Dieting should be begun during the first stage-indeed, as soon as the disease was diagnosticated. Albuminous substances and carbohydrates should form the substance of the three principal meals, and milk the chief drink. In the second stage cough mixtures should be avoided as much as possible and food should be taken at least six times in the twenty four hours. This included milk with limewater given early in the morning, at bedtime, and between meals, but the milk should never be given at the same time with the beef juice. In the third stage milk and limewater could be alternated with predigested food, such as beef peptonoids. The following might serve as an example of a dietary in the first stage of the disease: On awakening, the patient was to take half a pint of a mixture of equal parts of hot milk and Seltzer water, sipping it in the course of half an hour. The breakfast might consist of oatmeal or cracked wheat with a little sugar and plenty of cream, rare steak or chop, cream toast, half a pint of milk, and a small cup of coffee. At ten o'clock in the morning half a pint of milk or a small teacupful of expressed beef-juice with stale bread would constitute an appropriate luncheon. The midday meal might consist of fish, chicken, or scraped-meat balls, with stale bread and plenty of butter, baked apples and cream, and milk. Another luncheon, at four o'clock in the afternoon, might consist of a bottle of kumyss and a sandwich of rare scraped beef. At six o'clock in the afternoon a substantial dinner might be taken consisting of soup, rare roast beef or mutton, game, stale bread, and spinach, cauliflower, or other fresh vegetables, according to the season.

Dr. E. Le Fevre said that he thought those who had done much dispensary practice had been impressed with the tolerance of the alimentary tract to the retention and absorption of food of all kinds. From one point of view, the prognosis could be made almost entirely on this one factor. For example, in those who had the power of absorbing food in almost any quantity and at almost any time, the prognosis was comparatively favorable, notwithstanding that there might be an extensive infection. Although we all recognized the necessity for forced feeding, it was almost impossible to carry out this treatment in the city. In the country, where patients could walk about in the fresh air, it was comparatively easy to get them to take large quantities of food; it was very different however, with patients living in close and overheated rooms in the city, no matter how carefully we tried to gauge the quantity of food and regulate the intervals between the meals. Regarding the climatic treatment, he said that although a climate might be admirably suited to the phthisical subject, and the elevation above the sea level also satisfactory, it was often impossible to secure proper food and proper cooking; and hence it was that these factors often more than counterbalanced the benefit derived from change of climate. Although milk contained the necessary elements of nutrition, he had often great difficulty in getting patients to take the requisite quantity of it. If it was taken between meals, they complained that it caused heaviness and discomfort. He had tried mixing it with limewater and adding carbonate of sodium and salt, and also the plan of giving it as a "milk-shake," but had found much difficulty in carrying out any of these methods. Like the author, he preferred a meat diet chiefly. Any one who had been fed on these meat balls or any of these special preparations knew that, no matter how tempting they might look, they soon cloyed the palate; hence he relied upon meat prepared in the ordinary way as long as possible. He had found that some patients did not improve until starches and sugars were added to the meat diet. The most unpromising cases were those in which the dyspeptic symptoms occurred early. These cases were not simple instances of dyspepsia; the symptoms were really a part of the systemic disease.

Dr. C. E. QUIMBY said that the general statements in the paper could not but meet with unquestioning approval. While admitting in the main the accuracy of the proposition that gain in weight was a direct index of improvement of the disease condition, he believed there were circumstances where this was not true. In an article he had written some two years since upon the treatment of phthisis by a special method he had used quite extensively, by which the respiratory functions and inferentially oxygenation were very greatly increased, he had referred to the fact that in many cases patients undergoing this treatment failed to make a gain in weight proportionate to the improvement in their pulmonary conditions, such as was often observed in connection with forced feeding and favorable climatic influences. Even when the change in the local process was so rapid and favorable as to cause surprise, there was frequently only slight gain in weight. He had therefore been led to the conclusion that gain in weight and improvement in nutrition were not synonymous or necessarily in fixed ratio. It should be remembered that many persons became overfat from lack of oxidation; a condition which was one of defective rather than improved nutrition, and which might be developed in phthisis when the powers of intestinal absorption were in excess of the capacity of a crippled lung to take in oxygen. He had therefore come to regard the muscular tissue as a more certain index of the character of systemic nutrition than the adipose tissue. When the flesh became firmer in the calves of the legs or on the shoulders he felt that the patient was improving decidedly, even though there was but little increase in weight.

Instead of dividing phthisis into the three classical stages, he had found it convenient to divide it into what might be called "phthisis florida," where there was apparently an extensive localized hyperæmia associated with the tubercular process, and into cases of disseminated phthisis, where the process was going on much more gradually and tubercular tissue was breaking down slowly and being replaced by fibrous tissue. In the first form he questioned whether forced feeding was desirable. He was inclined to believe that it was detrimental in precisely the same way that exercise of the lung was detrimental to the local condition. He believed that a partial starvation diet would tend to diminish the intensity of the inflammatory processes more than forced feeding. In reference to stimulants, he said that, where there was a tendency to marked fever, early or late in the disease, and whenever there was a tendency to intense congestion of the lungs, as shown by hæmorrhages and by the physical signs, he would certainly withhold alcoholic stimulants; but in other cases it was his general rule to attempt very early in the disease to favor assimilation by giving his patients a good glass of sherry with their meals. He was also sufficiently old-fashioned to believe that mercury was useful wherever it was desirable to stir up the assimilative processes. An occasional mercurial purge, followed by Warburg's tincture, not only relieved intestinal fermentation and dyspepsia, but, he believed, was a powerful stimulant to the nutritive processes. It was also very important to attend to the thorough clearing out of the lower bowel. This had been impressed upon him some years before by a phthisical patient who had had occasional elevations of temperature which he had not been able to account for until he had discovered a distended colon. The use of high enemata had put an end to these exacerbations. Since that time he had been careful to keep himself and the patient well informed as to the activity and condition of the bowels. He had seen very little of that disgust for food in patients undergoing the special treatment previously referred to, about which so much had been said in connection with phthisis. He could recall many cases where the digestion had remained good from first to last. This, he thought, was possibly explained by the effect of that treatment in promoting the circulation and the activity of the assimilative processes.

Dr. F. M. Crandle thought that all would agree with the author as to the advisability of giving meat very largely. He had seen three patients this winter who had been under a quack's treatment, which had consisted of the use of large quantities of hot water and beef. One of these patients had taken nothing but meat for three months, and there had been a general as well as a local improvement. There had been no craving for other food. In another case, that of a child, the meat had been taken several times a day quite greedily. This had led him to push this treatment more actively than formerly, and he had found that, though there was usually a certain amount of disgust for food at the end of the first two weeks, if the treatment was persisted in this quickly disappeared.

Dr. Reginald H. Sayre wished to corroborate the statements made by the last speaker. He knew of a patient who had taken a specially prepared form of beef for over two years, almost to the exclusion of other food. In tuberculosis of other parts of the body than the lungs it seemed to him exceedingly important that the patient should be overfed in order that the tissues might be placed in the best possible condition for withstanding the tubercular process. The effect of such treatment was very manifest in children with Pott's disease and tubercular joint disease.

Dr. Newberg, of Chicago, said that in the dietetic treatment of all patients he would be largely governed by Sir William Robertson's dictum, that most people had a true palate-in other words, he believed in patients eating what agreed with them. A newly born baby required, first, air, secondly, sleep, and thirdly, food; and he believed in the majority of diseases it was well to take these three factors into consideration. He thought this very general rule would hold good also in phthisis. In neurasthenic patients he believed it was well to give milk in as non-stimulating a form as possible, and here matzoon was appropriate. In less nervous patients, however, he thought kumyss was more suitable. The majority of physicians seemed to overlook individual peculiarities. For a year and a half, while at Charity Hospital, he had seen a large number of phthisical patients in all stages of the disease, yet these had seemed to do well on almost any kind of diet.

## Nook Notices.

Hospitals, Dispensaries, and Nursing. Papers and Discussions in the International Congress of Charities, Correction, and Philanthropy, Section III, Chicago, June 12 to 17, 1893, Edited by John S. Billings, M. D., and Henry M. Hurd, M. D. Baltimore: The Johns Hopkins Press. London: The Scientific Press, Limited, 1894. Pp. xiv-719.

The papers and discussions included in this volume constitute the transactions of Section III of the International Congress of Charities, Correction, and Philanthropy that was held during last June in Chicago. The first paper in the volume is the address of the chairman, Surgeon John S. Billings, of the army, on The Relations of Hospitals to Public Health, especially in the training that is afforded physicians and nurses. Lord Cathcart, in a paper on The Medical Charities of the English Metropolis,

calls attention to the lack of co-operation between those charities, and explains the scope of their work. Miss Hampton, in a paper on Educational Standards for Nurses, calls attention to the insufficient instruction given nurses in many training schools, and urges that these schools should unite to establish a standard of education from which all may be judged. Mr. H. C. Burdett's paper on Hospital Finance and Methods of Keeping Accounts has been elaborated into a volume that was recently noticed in these columns. Lieutenant-Colonel J. Lane Notter, A. M. S. Eng., in a paper on The Applicability of Hygiene to the Conditions of Modern Warfare, considers how far much of the disease and suffering incidental to military operations may be mitigated if not obviated.

Richard Wood, of Philadelphia, in a paper on The Trustee of the Hospital, says that the relation between the managers of a hospital and its medical staff should be almost, though not quite, that of partnership; that the balance should be in favor of the trustees is shown by the statement that "the staff should respect the views of the managers touching certain methods of medical and surgical practice." This position is not new, it is general throughout the country; and yet the author himself, in his reference to military and naval hospitals, recognizes that the institution can be most efficiently administered without trustees-but without physicians it would undoubtedly collapse. The objection to the interference of trustees in the management of the medical matters of the hospital was indicated by Mr. H. C. Burdett in his discussion of this paper. This topic is further discussed by Dr. E. Cowles, in a paper on The Relations of the Medical Staff to the Governing Bodies in Hospitals, in which the position is taken that the former should properly subordinate itself to the latter. Mr. H. Merke contributes a paper on The Administration of Hospitals.

Miss L. L. Doch furnishes a paper on The Relation of Training Schools to Hospitals.

In the discussion on Dr. H. M. Hurd's paper, on The Relation of Hospitals to Medical Education, Mr. Burdett, than whom none can allege a greater acquaintance with hospitals, urges that every medical man be paid for the services he renders hospitals. This position is tenable on every ground of equity and justice. The community would hold up to contempt and condemnation the man or the corporation that took advantage of the needs of a workingman to give him food and shelter in return for his labor and the experience he was acquiring; but throughout this and, save in army, navy, and marine and railroad hospitals, and in insane asylums, physicians are serving on the visiting and resident staff without remuneration, with hardly an exception, ostensibly because they are acquiring experience, actually because it is assumed to be useless to pay for what may be obtained for nothing. Why not make nurses serve in like manner for equally just or unjust reasons? Mr. Burdett is right; to pay salaries would "confer an immense justice on the younger members of the medical profession."

Mr. J. R. Lathrop's paper, on Hospital Accounts and Methods of Bookkeeping, explains the system in vogue at the Roosevelt Hospital.

Dr. H. M. Lyman advocates the advantages of paying patients in hospitals, inasmuch as they serve to make the institutions self-supporting. The Presbyterian Hospital of Chicago, in allowing physicians unconnected with the visiting staff to treat pay patients, sets an example for the large institutions of this city that do not offer such privileges.

Dr. G. H. M. Rowe, Dr. Moritz Pistor, Dr. A. Herbert, Dr. W. Douglas Hogg, and Dr. M. L. Davis have interesting papers on Wards and Hospitals for Contagious Diseases.

Dr. H. B. Stehman and Miss M.  $\Lambda$ . Boland have papers on Hospital Diet.

Dr. A. C. Abbott furnishes a paper on The New Laundry of the University of Pennsylvania Hospital.

Passed Assistant Surgeon Gatewood has contributed an interesting paper on Naval Hospitals; Dr. Grossheim, one on Military Hospitals; Surgeon Stoner, one on Marine Hospitals; Mr. Francis Vacher, one on Cottage Hospitals; and Dr. A. Baginsky, Dr. W. W. Ord, and Miss M. L. Rogers have papers on Children's Hospitals.

There are several papers on different hospitals in this country, on nursing in various countries, and on first aid to the injured.

The papers express the views and indicate the experience of many competent observers, and the volume is an interesting and valuable contribution to the literature of hospitals and hospital administration.

Burdett's Hospital and Charities Annual, 1894. Containing a Review of the Position and Requirements, and Chapters on the Cost of Management, of the Voluntary Charities, and an Exhaustive Record of Hospital Work for the Year, etc. Edited by Henry C. Burdett. Author of Hospitals and Asylums of the World, etc. London: The Scientific Press (Limited), 1894. Pp. cccxxviii to 522. [Price, 5s.]

We are glad to note in the appearance of this volume the presage of the truth of the author's prefatory statement, that its annual publication is an established fact; for we know of no layman who has shown a more intelligent interest in hospitals and the features pertaining to their administration than Mr. Burdett, or who is as competent to undertake the compilation and arrangement of the information this work contains. Like many another book, it inadequately represents the great amount of labor that has been expended in its production, and only those who have undertaken work of this character can appreciate that labor.

In his first chapter Mr. Burdett presents statistics that give an idea of the vast interests involved in the topics under consideration. The combined revenue of the charities that have their headquarters in London amounts to seven million pounds sterling, a sum equal to half of the whole capital of the Bank of England, and a sum that is greater than the total annual revenue of all the British colonies, except New South Wales, Victoria, and Canada.

Another presentation of the subject is the fact that the amount raised annually in the United Kingdom by the voluntary rate in aid of charities far exceeds that levied by the income tax, and is equal to the whole yearly contributions to the national finances in Pitt's time.

He also refers to the disappearance of the prejudice against hospitals, citing the enforcement of the isolation of contagious diseases provided for by statute as evidence of the present feeling

The author cites the objection of the Boston City Council to the establishment of outpost, or emergency, hospitals in districts remote from a central institution, because the administration of these emergency hospitals makes use of them as schools of medical observation and retains patients that should be transferred to the central hospital. Those familiar with the duties of the medical staff of such institutions will concede that such an opinion is not without foundation; but the circumstances attending an acute medical or surgical case may be such that it would be very desirable for the physician that first assumed charge of the patient to continue his supervision; and often these patients are in such a precarious condition that a transfer elsewhere, by means of either a boat or an ambulance, would seriously jeopardize the chance of recovery or would

even hasten death. The writer has known patients with pulmonary tuberculosis to be so retained for several days rather than expedite death by transferring them to the central hospital. We believe that the administration of such an institution is justified in a city like New York or London, where distances are so great. The three emergency hospitals maintained by the city and the down-town hospital maintained by the New York Hospital do work that compensates for any unnecessary detention of patients.

The author refers to one crying need of all metropolitan hospitals—convalescent homes. It is indisputable that the usefulness of many institutions is crippled because they either retain patients too long, or do not retain them long enough. One of our New York hospitals had such demands upon it last winter that by the time admission of an applicant to the institution was possible he either had passed the crisis of the disease and was convalescing or had died.

The author is fully justified in his demand that all general hospitals should be provided with a ward for delirium tremens and doubtful cases. Alcoholism is not to be regarded as trivial, and every hospital physician will recall cases, besides those of fractured skull that were diagnosticated erroneously as alcoholism, in which the degree of intoxication seemed not unusual, but death terminated the case. Far better is it to treat all such cases than to be negligent in one, for the hospital physician is "his brother's keeper."

There is, indeed, need for more consumption hospitals, not only in London but throughout the world. In their establishment it would seem best to locate them elsewhere than in the city; in fact, we do not think that such institutions, except as emergency hospitals, should be allowed in metropolitan districts, but should be located at some sanitary site near the city.

The author's comment on the recent international and nursing congress are interesting, and we concur with him that decennial meetings are sufficiently frequent. He says of American nurses that they "have a breezy intelligence and independence that are very entertaining and attractive. They thoroughly believe in themselves and their mission; and, if they err at all, it is on the side of inclining to the refusal of all assistance from their friends and well-wishers."

The account of the effort to create a central hospital board for London is very interesting, but we fail to note any duty of such a board that is not already performed by the trustees or board of governors of a well-regulated hospital. There seem to us to be various obstacles to the successful accomplishment of such a plan, and we shall watch with much interest the manner in which our London brethren make this body a fait accompli.

The chapter on the cost of hospital management gives many valuable data; the author maintains that fifteen per cent. should be the maximum percentage of cost of administration to that of treatment.

The hope is expressed that the authorities of the principal hospitals in the United States will co-operate with those of the United Kingdom by adopting a system of accounts that will secure uniformity and lead to important and useful conclusions. Such a step might serve as the precedent for uniformity in other matters, such as the tabulation of diseases, duration of treatment, mortality, surgical operations, etc., that would make these reports of far greater value than they are. Of some twenty-five institutions in this country, the author finds from the statements published in their annual reports that the cost of maintenance per diem varies from forty-two cents in the Charity Hospital, New Orleans, to six dollars and thirty-six cents in the Massachusetts General Hospital; these figures he accepts with reserve, remarking that there must be a reasonable mean between them, and that if it were true that a patient who re-

mained long enough at the former institution might gradually die of inanition, it seemed equally possible that he might be killed by luxurious living at the latter hospital. An analysis of his own tables will show some reason for the discrepancy; on account of climate it costs to heat the Charity Hospital about one third of what it costs to heat the Massachusetts General Hospital. Sisters of Charity perform the duties at the former institution, so that its salaries and wages account is more than twelve thousand dollars less. While the report for the Boston institution for 1892 is not at hand, that for 1891 states that 75,712 days of hospital treatment were afforded at a cost of one dollar and seventy-nine cents a day, and it does not seem possible that in 1892 only 23,275 days' treatment were afforded, making the daily cost more than six dollars.

One chapter gives the curious information that certain English hospitals require in-patients to provide certain articles of diet, clothing, and furniture, and even to pay for washing. It is almost supererogatory to state that Mr. Burdett unqualifiedly condenns such a system.

Two chapters are devoted to analyses of the Hospital Saturday and Sunday Organizations. It is mainly by the assistance of the latter of these bodies that the author has secured the adoption of a uniform system of audits and accounts.

It is a consummation devoutly to be wished for that some well-regulated city should establish a system of control whereby the multiplication of medical charities beyond the needs of the population could be prevented. We regret to say that Mr. Burdett is in error in stating that in "America every applicant is compelled to pay unless proof is afforded that his claim to free medical relief is based upon genuine necessity." Where a fee is exacted it is nominal, and no part thereof goes to the attending physician. So great is the competition for material among dispensaries that we have seen well-to-do patients unblushingly receive gratuitous medical services. Mr. Burdett's statistics show that in Dublin two in five, in Liverpool, London, and Edinburgh almost two in every five, and in Newcastle, Birmingham, and Manchester one in four of the population receives free medical relief as an out-patient. We think it is true that the larger the town the greater the abuse. While we entirely agree on every conceivable ground that every medical officer, whatever his position, attached to a hospital or medical institution should be paid for his services, we are not prepared to say that such a course would remedy the abuse of free dispensary relief.

While we have devoted considerable space to this interesting volume, perforce we have not considered many subjects of which it treats. Suffice it to say that all physicians interested in dispensaries or hospitals will find it a mine of valuable and suggestive information.

Tumors: Innocent and Malignant. Their Clinical Features and Appropriate Treatment. By J. Bland Sutton, Assistant Surgeon to the Middlesex Hospital, London. With Two Hundred and Fifty Engravings and Nine Plates. Philadelphia: Lea Brothers & Co., 1893. Pp. i to xvi-511. [Price, \$4.50.]
